2. The carburetors should be removed, disassembled, and cleaned every 6,000 miles. Refer to "Fuel System."

3. The petcock should be serviced every 3,000 miles.

450: Shut off the fuel; unscrew the petcock sediment bowl. Take out the O-ring and fuel filter screen. Clean the parts in solvent and inspect the screen for any holes or other defects. Replace it if damaged. Inspect the O-ring for any cuts or cracks. Reinstall the screen, O-ring, and bowl. Turn on the fuel and check for leaks.

Petcock components (500T)

1. Petcock body
2. Nut
3. O-ring
4. Filter screen

500T: The petcock filter screen is inside the gas tank. Disconnect the fuel lines, remove the tank from the machine, and drain off the gas. Unscrew the securing nut and carefully take out the petcock. Remove the securing nut and filter from the petcock. Wash the filter in solvent to remove any foreign matter. Replace the filter if it is badly clogged or punctured. Check the condition of the gasket and replace it if crushed or nicked. Installation is the reverse of the above. Be sure that the fuel lines are secured to the petcock with safety clips. Check for leaks before operation.

Air Cleaner Service

The paper element air cleaner should be cleaned every 3,000 miles and replaced every 6,000 miles, under normal conditions.

REMOVAL

500T

1. Remove the left and right sidecovers.
2. Remove the air cleaner covers.
3. Loosen the air cleaner hose clamps. Remove the element securing bolts, and take out the elements.

450

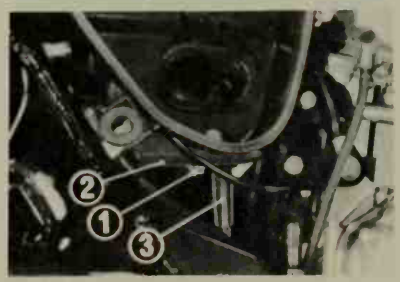
1. Open the seat. On CL models, the exhaust system must be removed.
2. Remove the left and right sidecovers.
3. Loosen the air cleaner hose clamps. Remove the air cleaner-to-frame securing bolt. Remove the bolt running through the center of the air cleaner elements.
4. Remove the covers and the air cleaner elements.

SERVICE

1. Brush off heavy deposits of dirt with a brush. Apply compressed air through the inside of the elements to blow off any remaining deposits.
2. Since this method will be only partially successful, replacement of the elements every 6,000 miles is recommended.
3. Inspect the element and connecting tube for any damage; replace any air cleaner found defective. An oil-impregnated element or one which cannot be cleaned sufficiently should also be replaced.
4. Inspect the area where the element is bonded to the mounting plate. If the bonding is cracked or separated, replace the element.

INSTALLATION

1. Check all rubber parts for deterioration and replace if necessary.
2. Be sure that the air cleaners are properly installed and that all connections are properly fitted and secured to prevent leaks.



Breather Element

The 500T is fitted with a crankcase rebreather. After removing the air cleaner elements, remove the bolt which secures the breather cover, and remove the cover and drain tube.

Remove the breather element from the air cleaner box. Clean the element in a clean solvent and dry thoroughly. Soak it in engine oil or gear oil (80 or 90W) and squeeze off the excess.

Check that the breather drain tube is clear; squeeze the end to remove any oil or water; clean out the inside of the breather case.

Install all components in the reverse of removal.

Bolt (1), breather cover (2), and drain tube (3) (500T)

Periodic Maintenance Intervals ①

Daily
- Brake adjustment
- Engine oil level
- Cable adjustments
- Chain slack
- Lights

Weekly
- Battery fluid level
- Spokes for tightness
- Tire pressure (cold)

Every 1500 miles
- Change engine oil
- Check disc brake fluid level

Every 2000 miles
- Clean final drive chain

Every 3000 miles
- Clean and gap or replace spark plugs
- Clean and gap breaker points
- Check ignition timing
- Adjust valve clearance
- Adjust cam chain tensioner
- Lubricate breaker point cam
- Service all grease fittings
- Clean fuel petcock
- Lubricate controls and cables
- Clean air cleaner elements
- Clean breather elements (500T)
- Inspect condition of chain and sprockets
- Check condition of all fuel lines
- Check carburetor operation
- Check brake pads for wear

Every 6000 miles
- Clean oil filter
- Change fork oil
- Replace air cleaner elements
- Adjust steering head bearings

Every 12000 miles
- Flush and renew disc brake fluid
- Repack wheel and steering head bearings

① Based on normal usage after break-in is complete.

Recommended Lubricants

Engine
- General—All Temperatures
  - SAE 10W-30, service rating "SE"
  - SAE 10W-40, service rating "SE"
- Alternate
  - SAE 30 — Above 50° F
  - SAE 20 or 20W — 32°-50° F
  - SAE 10W — Below 32° F

Forks
- ATF
- SAE 30W, SAE 20W

Control Cables
- 10W-30 motor oil
- Graphite-base lubricant
- Molybdenum disulphide-base lubricant

Tach. Speedo Cables
- Light-duty, lithium-base grease

Wheel Bearings
- Waterproof, medium-weight bearing grease

Steering Head Bearings
- Waterproof, medium-weight bearing grease

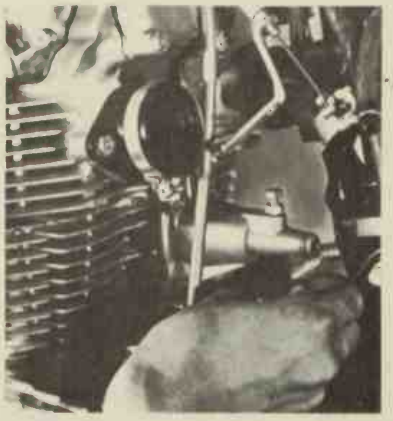
Grease Fittings
- Waterproof, medium-weight chassis grease

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information."*

CAM CHAIN ADJUSTMENT

1. The cam chain tensioner is located behind the cylinders and consists of a aluminum housing and a spring-loaded tensioner rod which is held in place by a lockbolt.
2. To adjust the cam chain, turn the engine over with the kick-starter; loosen the lock bolt nut, and back the bolt off one or two turns. The proper chain tension will be set automatically.
3. Tighten the bolt to secure the tensioner rod, then tighten the locknut.

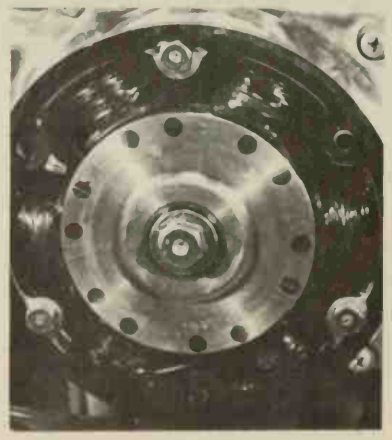


Adjusting cam chain tension

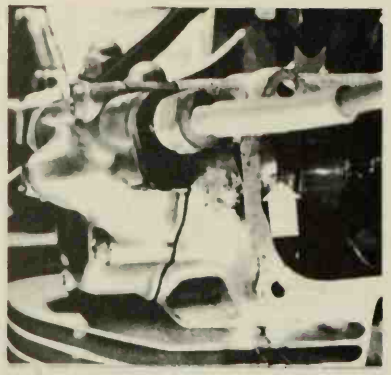
Alternate Method

1. Loosen the locknut and tensioner bolt.
2. Insert a piece of stiff wire, such as a straightened paper clip, into the tail section of the tensioner housing and hold it gently against the end of the tensioner rod (on early 450s, the rod protrudes from the housing).
3. Turn the engine over slowly in the normal direction of rotation. You will be able to feel the tensioner rod move back and forth as chain tension varies.
4. Do this several times and note that point at which the rod is farthest in. Stop the engine at this point. Tighten the tensioner bolt and locknut.

CAUTION: *Never push on the tensioner rod to force it in; do not hold the rod in place while tightening the bolt. All tension must be supplied by the tensioner spring.*

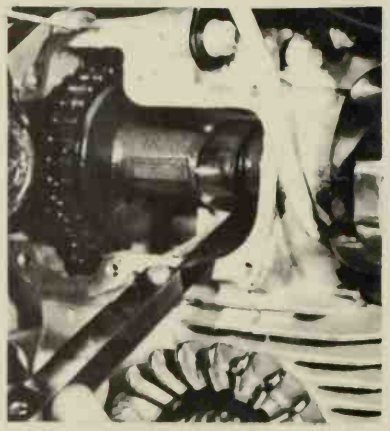


Checking cam chain tensioner rod movement



VALVE ADJUSTMENT

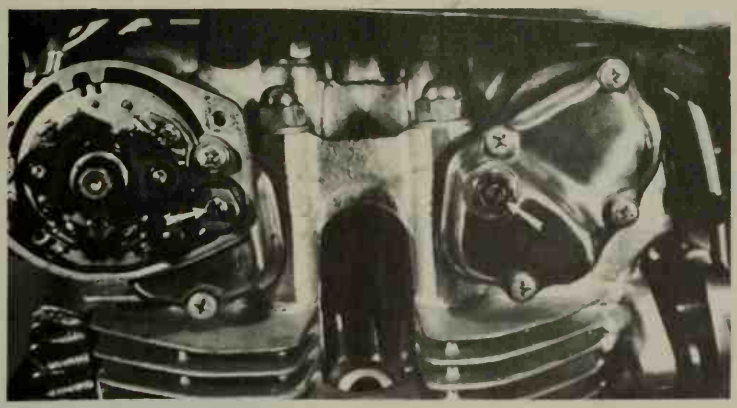
NOTE: *The valves must be adjusted when the engine is cold.*



1. Lift the seat. Shut off the fuel, disconnect the line(s) at the petcock, and remove the gas tank. Remove the carburetors.
2. Remove the intake and exhaust cam covers at the rear and front of the cylinder head.
3. Remove the alternator rotor cover. Remove the spark plugs.
4. Valve adjustment is made by turning the cam follower shafts which are eccentric. Clearance is measured between the camshaft lobe and the cam follower pad.

"LT" rotor mark aligned for left cylinder valve clearance setting

If the index marks are aligned, turn the engine 360° to adjust the valves



Valve clearance is measured between the lobe and the cam follower pad

Clearance for all valves is 0.03 mm (0.0012 in.).

5. Turn the alternator rotor in the normal direction of rotation (counterclockwise) until the "LT" mark on the rotor aligns with the stator index mark. If the index marks of the intake and exhaust cams are aligned with the marks on the bearing holders on the right ends of the cam, turn the alternator rotor 360°. The left cylinder is now at top dead center on the compression stroke.
6. Check the clearance of the valves for the left cylinder. If clearance is correct, a feeler gauge of 0.03 mm/0.0012 in. will be a light drag fit between the cam lobe and the cam follower pad.
7. If adjustment is necessary, loosen the locknut and turn the cam follower shaft as necessary to effect proper clearance.

Do not turn the shaft more than 180°.

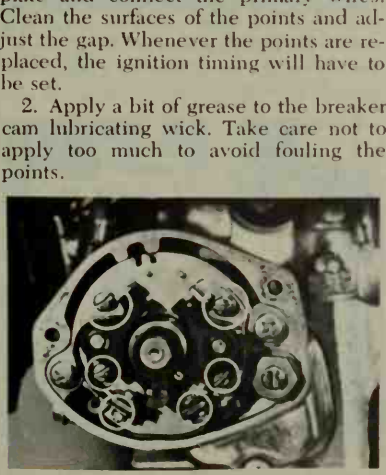
8. Tighten the shaft locknut, and recheck the clearance.
9. Turn the alternator rotor 180° so that the "T" mark on the rotor aligns with the stator index mark and check that the right cylinder is at TDC on the compression stroke. Check valve clearances and make adjustments as outlined in Steps 6-8.
10. Valve clearance is *decreased* by turning the shafts in the following directions:

The index marks on the cam follower shafts must point away from the center of the head

Left-side	EX—turn counterclockwise IN—turn clockwise
Right-side	IN—turn counterclockwise EX—turn clockwise

To increase clearance, reverse the above directions.

CONTACT BREAKER POINTS



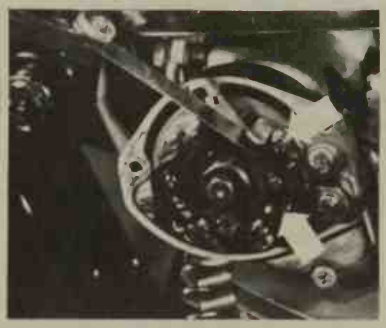
Location

1. The points are located in a case on the left-side of the cylinder head, and are operated off the exhaust camshaft. The timing advance mechanism is fitted behind the breaker point base plate.

Replacement

1. If replacement of the points is necessary, this is easily accomplished by disconnecting the primary wire, removing the two point securing screws, and taking off the points. Install the new points after thoroughly cleaning off the contact surfaces with a non-oily solvent, and adjust the gap. If a breaker plate assembly is purchased, simply disconnect the yellow and blue point wires from the wiring harness and remove the two breaker plate screws. Install the new breaker plate and connect the primary wires. Clean the surfaces of the points and adjust the gap. Whenever the points are replaced, the ignition timing will have to be set.

2. Apply a bit of grease to the breaker cam lubricating wick. Take care not to apply too much to avoid fouling the points.



Remove mounting screws and disconnect primary wire (circles) for point removal

Gapping

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the points cover.
2. Using the rotor bolt, turn the engine over until one set of points is open to their maximum gap.
3. With the proper feeler gauge, check the gap. The proper specification for all models is 0.3–0.4 mm (0.012–0.016 in.).

Loosen the two screws (arrows) to adjust the point gap

4. If adjustment is necessary, loosen the two screws which secure the points to the base plate, and use a thin screwdriver at the pry slot provided to bring the gap to the proper specification.

NOTE: *Loosen the screws just enough to allow the points to be moved. If too loose, the points will snap shut instead of holding the adjustment.*

5. Tighten the screws and recheck the gap. It may change slightly when the screws are tightened.
6. Repeat the procedure for the other set of points.
7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the set of points should be replaced.

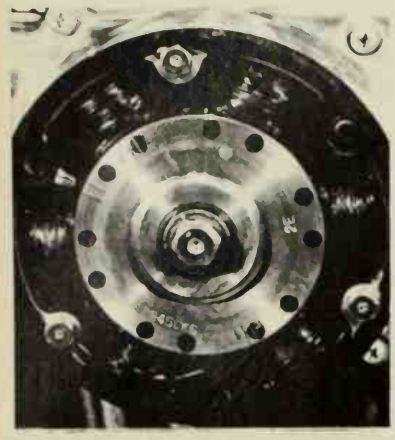
Lubrication

1. On all models it is necessary to lubricate the cam follower fiber heel and the pivot point of the contact breaker occasionally. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.
2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.
3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.
4. The lubricating wick should be adjusted so that it just contacts the breaker cam.
5. If the wick is missing the grease can be applied sparingly to the cam itself.

IGNITION TIMING

NOTE: *Points must be cleaned and gapped before checking timing. Dirty points will cause inaccurate readings.*

The method of adjusting the timing is the same regardless of the type of equipment used. The *left* cylinder is set *first* and timing is adjusted by moving the base plate. After the left cylinder is correctly timed, the right cylinder can be checked, and adjusted if necessary. To adjust the right cylinder timing, the point gap is varied so that the points open at the instant the timing marks align. A change in the point gap of 0.1 mm (0.004 in.) will change the timing 10°. Increasing the point gap will advance the timing, while decreasing it will retard the timing.

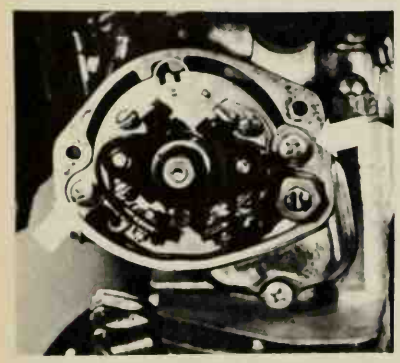


If correct timing cannot be accomplished with both point gaps set in the correct range of 0.3–0.4 mm (0.012–0.016 in.), the points should be replaced.

Dynamic Timing

1. Remove the alternator cover so that the timing marks are visible, and remove the points cover.

NOTE: *A white grease pencil or some paint can be used on the rotor and stator timing indicator marks to increase their visibility under the strobe light.*



2. Hook up the timing light according to the manufacturer's instructions. Most lights use the vehicle's own battery as a power source.
3. Start the engine, set the idle at 1,100 rpm, aiming the light on the rotor. Note the following:
   a. At idle, the "LF" (left cylinder) mark or the "F" (right cylinder) mark on the rotor should line up with the timing indicator on the stator, depending on which plug the strobe right is connected to;
   b. As the revolutions increase past 1,800 rpm, the "LF" or the "F" mark should be seen to move in a direction opposite that of the crankshaft rotation;
   c. Finally, at full advance (about 3,200 rpm and above), the twin rotor marks must line up with the timing indicator mark on the stator.
4. The full advance reading is the most important. If the rotor marks and the stator indicator do not align, proceed as follows:
5. Time the *left* cylinder *first*. Loosen the two screws which secure the breaker base plate just enough to allow the plate to be turned. Using a thin screwdriver applied at the pry point provided, rotate

Left cylinder timing when fully advanced

the plate in the direction necessary so that the timing marks align.

Rotating the plate clockwise advances the timing; rotating the plate counterclockwise retards the timing.

Adjust ignition timing by loosening the screws (arrows) and rotating the plate with a screwdriver applied to the pry point (circle)

Tighten the base plate screws and recheck the timing.

6. Connect the timing light to the right cylinder and check the timing as for the left cylinder this time using the "F" mark on the rotor.

If the right cylinder timing is incorrect, loosen the two screws which secure the right cylinder's points to the base plate.

NOTE: *The point set on the right of the breakerplate is for the right cylinder.*

Open or close the point gap so that the timing marks align as the points open, but keep the point gap within 0.3–0.4 mm (0.012–0.016 in.).

7. After the ignition timing is set, recheck the point gaps. Both must still be within the proper specification (0.3–0.4 mm/0.012–0.016 in.).

If either gap is not within this value, increase or decrease it as necessary so that it is. Increase or decrease the other point gap by the same amount. Both must be within the given range.

After making any adjustment to the point gap, the timing will have to be readjusted.

If the gaps have been changed by equal amounts, it will only be necessary to adjust the timing by moving the base plate.

If proper ignition timing is not possible, replace both sets of points, since the fiber heels are probably worn.

Static Timing

1. Remove the alternator cover, points cover, and the intake cam cover.

2. Remove the spark plugs and hook up the tester.

NOTE: *The point set on the left of the breaker plate is for the left cylinder.*

3. Turn the engine over so that the left cylinder is on the compression stroke (the left intake valve will go down and come up). Turn the engine over slowly in the normal direction of rotation (counterclockwise). At the instant in which the "LF" mark on the rotor aligns with the index mark on the stator, the left points should begin to open as indicated by the reaction of the test light or the meter.

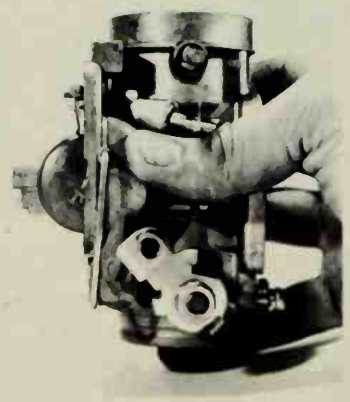
4. If the points open before the marks align, the timing is too advanced. If they open after the "LF" mark passes the index, the timing is too retarded.

5. If the timing is not correct, set the "LF" mark so that it is aligned with the index mark with the piston on its compression stroke. Loosen the two screws which secure the breaker base plate and rotate the plate until the light or meter indicates that the points have just opened. Tighten the base plate screws and recheck the timing.

6. After completing the timing for the left cylinder, connect the light or meter to the points for the right cylinder. Turn the rotor 180° counterclockwise until the "F" mark aligns with the index mark; at this point the right set of points should just open. If the timing is incorrect, align the "F" mark with the index mark and increase or decrease the point gap so that the points just open as indicated by the light or meter. Refer to Steps 6 and 7 under "Dynamic Timing," above. Tighten the set screws and recheck the timing and the point gap for both cylinders. Note that both gaps must still be within specifications.

CARBURETORS

Three adjustments to be made to the carburetors are the float level, the idle mixture, and the idle speed. For the first of these, the carburetors must be removed from the motorcycle.



Adjusting Float Level

Generally, float level will not need adjustment unless the carburetor has been disassembled, fuel delivery problems have been noted, or considerable mileage has been covered.

1. Remove the carburetors from the motorcycle as outlined in the "Fuel Systems" section.

2. Remove the float bowl. Remove the float bowl gasket.

3. Float level is defined as the measured distance from the float bowl mating surface on the carburetor body (gasket removed) to the top of the float, when the tang of the float is just touching the end of the float needle. A special gauge is available to check the float level although a vernier caliper can also be used.

Checking float level

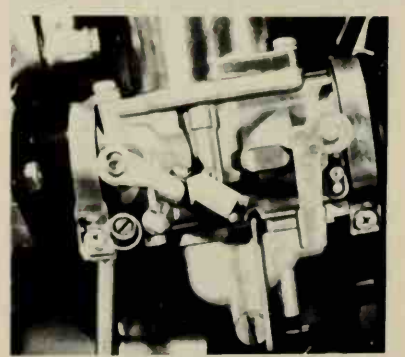
4. With the carburetor held as shown, measure the distance from the float bowl mating surface to the top of the float when the float tang is just touching, but not depressing, the float needle.

Correct float level for all models is 20.0 mm (0.79 in.).

5. If the adjustment is necessary, bend the float tang *only* to raise or lower the float level.

Be sure that both carburetors are set to the same float level.

6. Float level will not be correct if the needle is worn, or if there is foreign matter on the needle seat.



Idle Speed and Mixture

NOTE: *These items must be adjusted when the engine is at operating temperature.*

450 AND 500T

1. Remove the caps from the pilot screws (500T).

2. Check that the throttle cable has enough slack so that the throttle plates are not held open by their cables. Check by starting the engine and turning each stop screw out by about one turn. If idle speed does not decrease, the plate(s) are being held open by the cable(s).

Carburetor throttle stop (arrow) and pilot (circle) screws

3. Turn the pilot screws in very carefully until they are lightly seated, then back each one out one turn for the 450, or 1½ turns for the 500T.

4. Set the idle speed to about 1,200 rpm, turning the stop screw for each carburetor by equal amounts if adjustment is necessary to achieve proper idle speed.

5. Disconnect one spark plug lead. Adjust the stop screw for the other cylinder so that the engine runs on one cylinder as slowly as possible. Turn the pilot screw in or out until the engine runs smoothly. It should not be necessary to turn the pilot screw more than one-half turn in either direction from the standard setting.

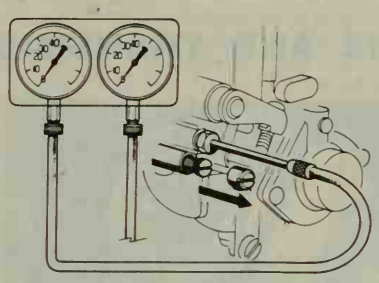
6. Connect the other spark plug lead, rev the engine a few times to clean out the engine, and then repeat this procedure with the other cylinder.

7. When both carburetors have been set, connect both plug leads. Engine idle speed will be high, so turn each stop screw out by equal amounts so that an idle of 1,100 rpm is obtained.

8. Check that the two carburetors are synchronized by opening and closing the throttle while watching the throttle stop screws. Both screws must begin to move at the same time when the throttle is opened. If one begins to move before the other, use the cable adjusters on the carburetors so that the movement of the stop screws is synchronized.

This cable adjuster is used to synchronize the throttle plates

9. Snap the throttle open and closed several times to make sure that synchronization is maintained.



10. Adjust the throttle cable free-play using the adjuster near the twist-grip so that the throttle has 10–15° of free rotation before the stop screws begin to move.

11. Install the pilot screw caps on the 500T so that the stop is pointed downward.

500T ONLY

The 500T is equipped with vacuum gauge fittings to adjust idle speed and mixture if such gauges are available.

1. Raise the gas tank as far as possible using longer fuel lines from the petcock to the carburetors.

Vacuum gauge installed on carburetor (500T)

2. Remove the vacuum gauge plugs from the carburetors and fit the vacuum lines (Tool No. 07510–3000200) and vacuum gauges (Tool No. 07504–3000100).

3. Loosen the cable adjuster locknuts and turn the adjusters in to allow a good amount of play in the cables.

4. Remove the caps from the carburetor pilot screws. Turn each screw in carefully until it bottoms, then turn each out 1½ turns.

5. With the engine idling, adjust the throttle stop screws to yield an idle speed of 1,100 rpm.

6. The vacuum gauges should show equal readings. Normal vacuum is 200–240 mm Hg. The two cylinders must be within 20 mm Hg of each other. Turn either or both of the throttle stop screws until both gauges give the same reading.

7. Turn the pilot screw on either carburetor in or out until the highest rpm is reached. It should not be necessary to turn the pilot screw more than ½ turn from the standard setting. Repeat the procedure with the other carburetor.

8. Readjust the vacuum readings and idle speed with the throttle stop screws if necessary.

9. Install the caps to the pilot screws with the stops pointed downward.

10. Synchronize the carburetors and adjust the cables as outlined in Steps 8–10, above.

Be sure that all cable adjuster locknuts are tightened. When original fuel lines are installed, be sure that all connections are tight.

11. If the carburetors cannot be adjusted so that they are within 20 mm Hg of each other or if either is not within the 200–240 mm Hg range, check the following:

a. Air leaks around the intake manifold or air cleaner;
b. Ignition timing;
c. Tappet clearance;
d. Compression pressure;
e. Spark plug gap and condition of plugs.

Tune-Up Specifications

	450	*500T*

—— Not applicable

ENGINE AND TRANSMISSION

NOTE: *For engine component inspection techniques and procedures, refer to "Engine Rebuilding" in the General Information section.*

Engine Service

1. To remove the cylinder head, barrels, and pistons, the engine must be removed from the frame.

2. Crankcase cover components: oil pump, clutch, gearshift mechanism, alternator, and countershaft sprocket, are all accessible with the engine in the frame.

3. To remove the cylinder head, a special tool is needed to break the endless cam chain. A special tool is also needed to press on a new masterlink plate when joining the chain. Disassembly should never be attempted unless these tools and a new masterlink are available.

4. Read each procedure carefully before beginning so that replacement items such as gaskets, O-rings, etc., can be purchased beforehand.

ENGINE REMOVAL AND INSTALLATION

450

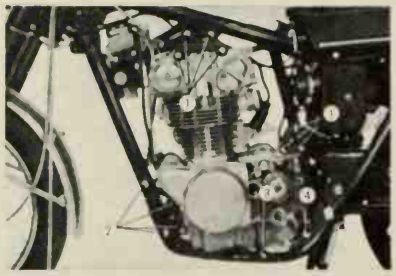
1. Drain the oil.

2. Turn the fuel tap off, disconnect the fuel lines and the balance line, and remove the gas tank.

To safely remove the tank, either drain it completely prior to removal, or obtain a four inch length of fuel line and two small clamps. Attach one clamp to the fuel tank's balance line. Disconnect the line; fit the spare length of fuel line to the tank fitting with the clamp already attached. This will prevent fuel from spilling out since the balance line must be disconnected for removal.

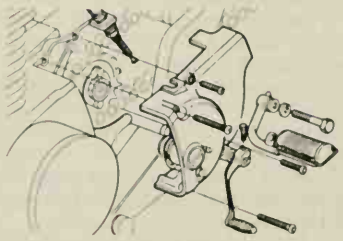
3. Remove the exhaust system.

4. Remove the air filters, disconnect the choke band from the left carb, loosen the carburetor-to-intake manifold clamps, and remove the carburetors.



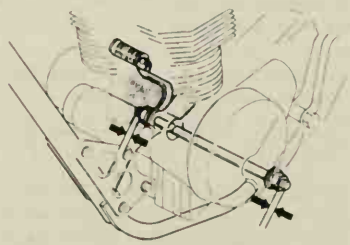
5. Remove the cable adjuster holder from each carburetor. Place the carburetors in a safe location.

6. Remove the footpeg and shift lever, and take off the left-side rear crankcase cover. Use an impact driver to remove the cover screws. Disconnect the clutch cable at the cover. Separate the chain at the masterlink. If an endless-type chain is fitted, loosen the rear brake adjuster, back off the rear axle chain adjusters, move the wheel forward as far as possible, and take the chain off the sprocket.



7. Disconnect the engine electrical leads (alternator, neutral switch, and points) at the connectors.

8. Disconnect the wires from the spark plugs and tuck them up out of the way. Loosen the spark plugs.



9. Disconnect the starter motor cable from the starter solenoid and disconnect the tachometer cable from the cylinder head. Disconnect the head breather tube. Remove the horn to prevent accidental damage.

Engine mounting bolts

Left rear crankcase cover removal

About the same number of threads should protrude from each side

10. Unscrew the engine mounting bolts and remove the engine from the left side.

Installation is a reversal of the removal procedure. Note the following points:

1. Do not forget to connect the battery ground cable when installing the engine mounting bolts. The cable connection must be clean and tight.

2. The chain master link clip should be installed so that the closed end faces the direction of forward rotation.

3. Make sure that the steel ball has been installed in the clutch release lever before reinstalling the crankcase cover.

4. Coat the threads of the cover screws with a lubricant or anti-seize compound and use an impact driver to secure them.

500T

1. Lift the seat, disconnect the fuel lines from the gas tank petcock, and remove the tank.

2. Remove the exhaust pipes and mufflers. This is done by removing the clamps at the cylinder head, removing the balance box bolts, removing the passenger footrests, and taking off the exhaust system as a unit.

3. Remove the tach cable from the head.

4. Disconnect the spark plug leads. Loosen the spark plugs.

5. Remove the left and right air cleaner covers. Loosen the clamps at the carburetors and the air cleaner bolts and remove the elements. Disconnect the choke band at one carburetor. Disconnect any overflow lines from the carburetors. Loosen the clamps at the manifold and remove the carburetors. Remove the throttle cable adjuster holder from each carburetor. Put the carburetors in a safe place.

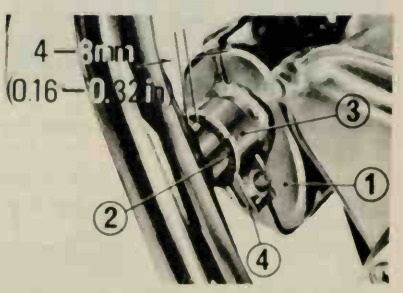
6. Disconnect the starter motor cable at the solenoid.

7. Disconnect the alternator switch, and points wires at the connectors.

8. Loosen the rear brake adjuster as much as possible. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the chain adjuster bolt locknut and screw out the adjuster bolt. Push the wheel forward as far as possible.

9. Remove the left rider footpeg. Remove the gearshift lever (carefully) from its splined shaft. Remove the rear portion of the left crankcase cover. Use an impact driver to remove the cover screws.

10. Remove the countershaft sprocket protector. Unbolt the sprocket lockplate, and slide the sprocket off its shaft.



11. Remove the horn and electrical wiring box.

12. Remove the engine mounting plates and bolts. Remove the engine from the frame.

Installation is the reverse of the above. Note the following points:

1. When installing the rider footpegs, the nuts should be tightened equally so that approximately the same number of stud threads protrude on each side.

2. Be sure that the battery ground cable connection is clean and tight.

Balance chamber (1); gasket (2); clamp (3); bolt (4)

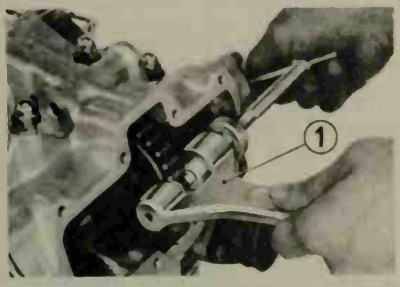
3. Use a lubricant or anti-seize compound on the crankcase cover screws and tighten them with an impact driver.

4. When refitting the exhaust system, be sure that the balance chamber gaskets are in place, flush with the ends of the chamber.

Clearance between the chamber ends and the exhaust pipes should be 4–8 mm (0.16–0.32 in.).

CYLINDER HEAD

Removal

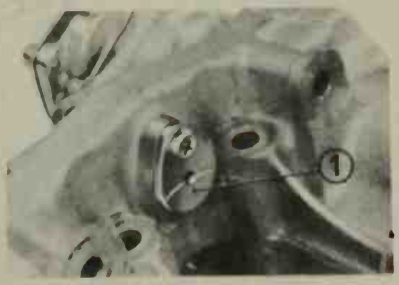


NOTE: *A special chain breaker/installation tool is needed to properly remove and install the head.*

1. Remove the engine from the frame.
2. Remove the eight bolts and take off the cam covers. Remove the gaskets if they adhere to the head. These gaskets must be replaced with new ones upon reassembly.
3. Remove the spark plugs; remove the alternator cover. Back off the cam chain tensioner bolt.

The cam chain masterlink has indentations on the rivets

4. Turn the engine over until the special masterlink on the cam chain is accessible on the intake side of the engine.
5. Wire up the cam chain on the lower side of the masterlink and below the exhaust cam sprocket so the ends will not slip into the engine when the masterlink is removed.
6. Use the chain breaker (Honda Tool No. 07968–2830100) to separate the chain at the masterlink.



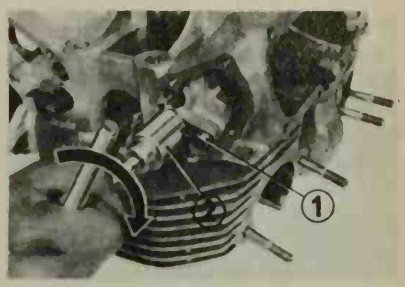
Separating the cam chain

7. Remove the eight cylinder head capnuts. These nuts should be loosened a little at a time and in a cross pattern. Loosen the outer four first, then the inner four; when all are loose, remove them from the studs.
8. Remove the cylinder head. If the head is stuck, tap around the mating surface with a plastic mallet, being cautious of the fins.
9. Remove the head gasket.
10. Attach the two ends of the cam chain to fixed points on the crankcase with pieces of wire to keep them from falling into the crankcase.
11. Note the hollow dowel pins on the cylinder-head mating surface. These must be in place on the two right-hand studs and the forward left-hand stud upon assembly.

Disassembly

1. Remove the front and rear cam chain guide rollers from the head by removing the four bolts.

Upper chain guide roller pin (1)



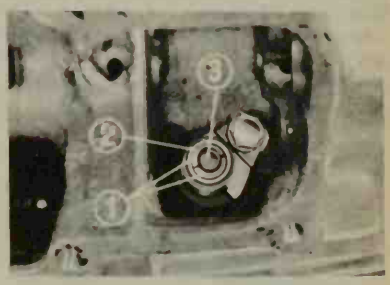
2. Remove the screw securing the upper chain guide roller pin. Remove the pin and roller.
3. Remove the locknuts from the cam follower shafts on the right and left-sides of the intake camshaft. Remove the right and left covers. Remove the intake camshaft.

CAUTION: *Note the camshaft shims. They must be installed to take up side-play.*

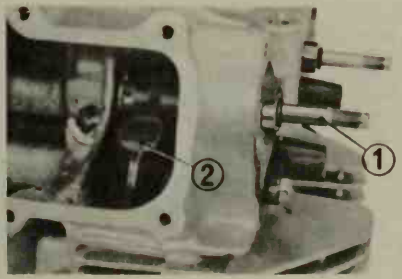
4. Remove the locknut from the tachometer drive side exhaust cam follower shaft. Remove the tachometer drive box and driveshaft from the head.
5. Remove the breaker point cover. Remove the locknut from the cam follower shaft. Scribe a line across the breaker point plate to the head to approximate ignition timing for assembly. Remove the two screws and remove the breaker plate complete with points. Remove the breaker cam bolt and pull off the timing advance assembly.
6. Remove the points housing after removing the securing screws. Remove the exhaust camshaft.
7. Pull out the cam follower shafts and the cam followers.

NOTE: *Keep each cam follower with its respective shaft. Also note the position of each follower and shaft in the head. Components must be installed in their original locations.*

8. Loosen the bolt on one of the torsion bar holders, backing it off several turns. Use the special tool (Tool No. 07973–2830001) to turn the torsion bar holder in the direction marked on the end of the bar to take the tension off the bolt. Then remove the bolt. Pull out the torsion bar; remove the outer arm. Repeat the procedure with the remaining torsion bars.

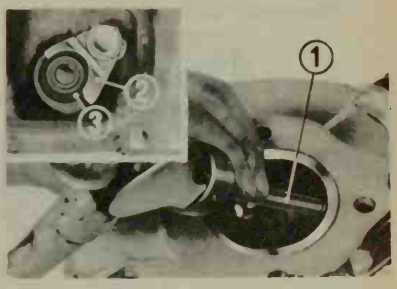


Torsion bar holder (1) and special tool (2)



NOTE: *As other torsion bar components are removed, keep each assembly together. All components must be installed in their original locations. Torsion bars should not be interchanged between cams or sides.*

9. To remove the valves, remove the valve keepers and spring retainer.
10. Inspect valve guides for condition before attempting removal. If replacement is necessary, remove the bolt securing the guide stopper. Remove the seal. Drive the guide out of the head with either the Honda tool (No. 07942-2830000) or a like substitute.
11. The exhaust cam right-side cover houses the tachometer drive mechanism. If removal is necessary, remove the phillips screw which secures the cable fitting; remove the bolt from the rear of the cover; remove the driveshaft and driven shaft.

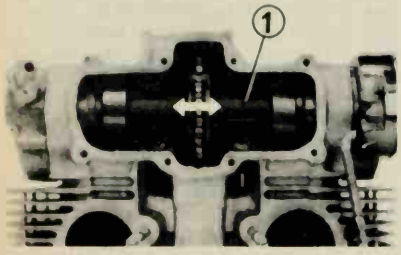


All washers and seals in this assembly should be replaced with new ones upon assembly.

Valve keepers (1); spring retainer (2); and valve (3)

Removing the cam follower shaft (1) and cam follower (2)

Removing a valve guide (1); valve guide stopper (2); and seal (3)



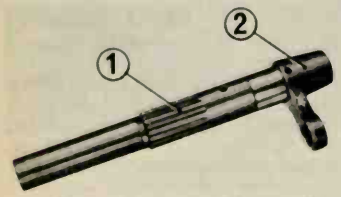
Inspection

For specifications of the top end components, refer to the charts at the end of this section.

CAMSHAFT

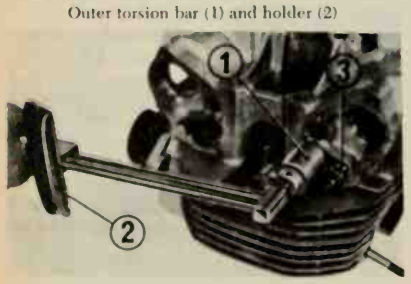
In addition to the usual checks, camshaft side-play must be checked.

1. Install each camshaft, along with its shims; lubricate, install, and secure the end covers. Check each camshaft for free rotation. Check each for side-play. Side-play must be within 0.05–0.35 mm (0.002–0.014 in.). If it is not, remove or substitute the proper camshaft shims.



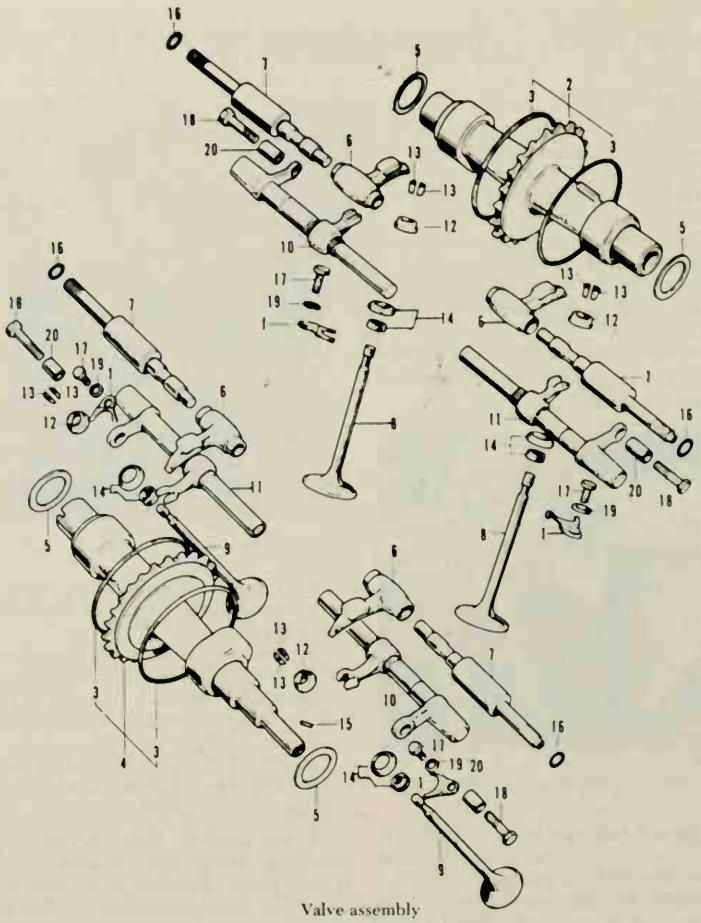
Checking cam side play

TORSION BARS



1. Check the condition of the torsion bar and outer arm assembly. The splines must be in very good condition. If either the arm or the bar show signs of heat damage or discoloration, replace them.

2. Check the tension of the torsion bar before reassembly. With the valve assembly in place, attach a torque wrench to the torsion bar holder and read the amount of force required to preload the torsion bar so that the bolt can be installed. This reading will yield the seated pressure of the valve which should be about 44–55 in. lbs. If tension is below 44 in. lbs, either replace the torsion bars or fit a thicker valve spring retainer.



If replacing the torsion bars, replace all as a set. If tension is satisfactory, do *not* fit a thicker retainer. Standard thickness is 7.0 mm. Service retainer thickness is 7.7 mm.

Outer torsion bar (1) and holder (2)

Checking torsion bar tension with a torque wrench (2) and adapter (1)

17. Bolt
18. Outer arm bolt
19. Lockwasher
20. Dowel pin

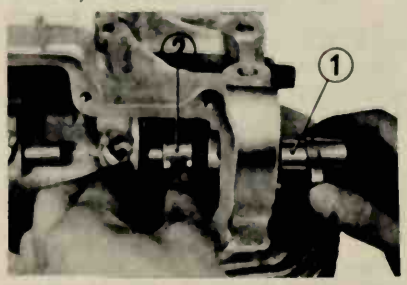
VALVES

Valves have stellite tips and edges. Machining or grinding the tips or edges of the head is not recommended.

Assembly

1. Install valve guides (if removed) using the guide driver (Tool No. 07942–1180100). Ream the guide after installation with Tool No. 07984–5900000. Be sure that the guide O-rings are installed.

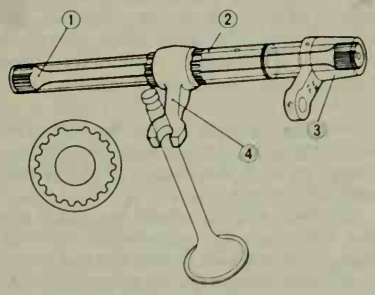
Valve assembly



1. Valve seal
2. Valve guide
3. Torsion bar
4. Valve guide keeper
5. Valve

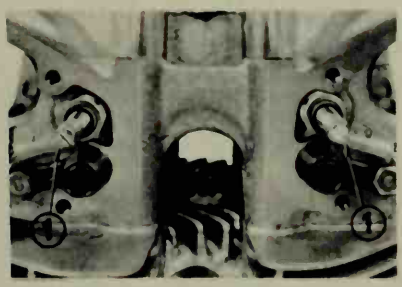
2. Install the valves and check seat width. If necessary, recut the seat and lap in the valves.

3. Install the upper cam chain guide roller and fit the roller pin ensuring that a new O-ring is installed in the groove of the pin.



4. Fit the valve guide stopper and seal. Install the outer arm, the valve, retainer, and valve keepers.

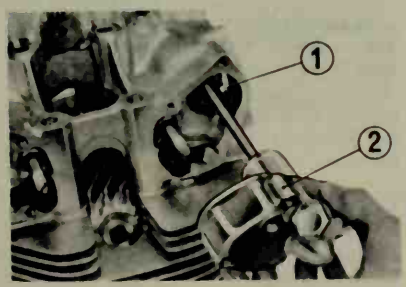
5. Assemble the torsion bar. Note that the torsion bars are marked "EX-L/IN-R" or "EX-R/IN-L"; be sure that each one is correctly installed.



Installing the torsion bar assembly (1) and outer arm (2)

6. Fit the torsion bar holder dowel pin; install the torsion bar and holder, then turn the bar in the direction marked so that the holder bolt can be installed and secured.

Valve spring assembly: 1, torsion bar; 2, torsion bar outer; 3, holder; 4, outer arm



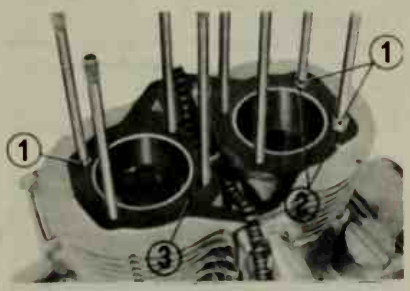
Cam follower shaft index marks (1) must point away from the center of the head

7. Lubricate the cam followers and shafts and install them. Note the small mark on the end of each cam follower shaft. This mark must point away from the center of the cylinder head and approximately 45° down from the horizontal when the shafts are installed.

8. Lubricate and install the intake cam and shims. Fit the cam covers. Be sure that cam side clearance is correct.

9. Lubricate and install the exhaust camshaft and shims. Lubricate the lips of the oil seal; install the breaker point housing. Install the tach drive box and driveshaft aligning the tabs on the drive gear with the slots in the camshaft. Check cam side-play as previously outlined.

When installing the tach drive box (2), align the tabs on the drive gear with the slots in the cam (1)



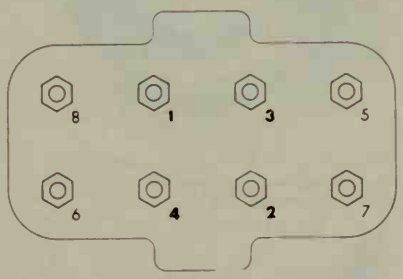
10. Install the timing advance mechanism, aligning the slot in the mechanism with the pin in the camshaft.

11. Fit the breaker plate, complete with points, and align the scribed timing mark if you made one. Check the ignition timing after assembly has been completed.

12. Install, but do not tighten, the cam follower shaft locknuts. Valves must be adjusted after assembly is completed.

Installation

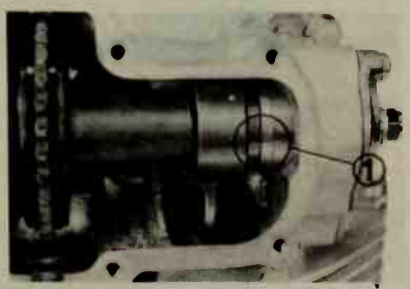
1. Fit a new head gasket to the cylinder and check that the dowel pins and O-rings are in place in the cylinder.



Be sure that the hollow dowel pins and O-rings (1 and 2) are in place before fitting the head gasket (3)

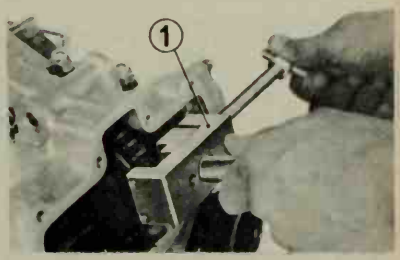
2. Install the head, pulling the cam chain up through it as it is moved down on the studs.

NOTE: *The stud threads should be cleaned and oiled lightly to ensure correct torque readings when securing the head.*



3. Fit the capnuts to the studs. Note that the nuts have special washers fitted beneath them for oil sealing.

4. Tighten the capnuts in increments of a few ft lbs until the proper torque of 25.3 ft lbs is reached. Note that the nuts must be tightened in a cross pattern beginning with the center nuts.



Cylinder head nut tightening order

5. Turn the engine over so that the "LT" mark on the alternator rotor is aligned with the timing mark. Turn the camshafts so that the index mark on the right-side of each camshaft is aligned with the mark on the cam cover bearing.

Align the cam marks with the index marks on the right side-covers

Installing the cam chain master link with the special tool (1)

6. Route the cam chain over the cam and under the idler sprocket. Use the cam chain installation tool (No. 07968–2830200) to install a new masterlink. Joining the chain on the intake side is easiest.

7. The remaining steps are in the reverse of disassembly. Be sure to adjust the cam chain and valves before operation.

CYLINDER AND PISTON

Removal

1. Remove the engine from the frame; remove the cylinder head. Remove the cam chain tensioner.

2. Lift up the cylinder so that it is several inches out of the crankcase. If the cylinder resists removal, tap around the base with a plastic mallet to free it.

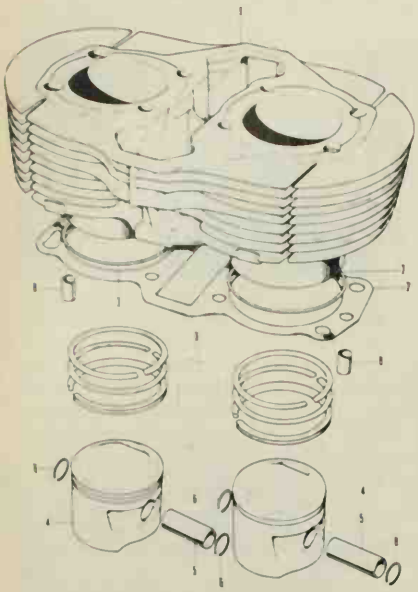
3. Stuff a clean rag between the bottom of the cylinder and the crankcase to protect the pistons and catch any pieces of broken piston ring when the pistons come out of the bore.

4. Remove the cylinder from the studs. Note the hollow dowel pins at the cylinder-crankcase mating surface.

5. Remove the piston wrist pin circlips with a needlenose pliers. Discard old circlips; new ones must be used on assembly.

6. Push out the wrist pin and remove the piston from the connecting rod.

CAUTION *Push the wrist pin out with a blunt drift using steady pressure. Do not attempt to strike or impact the drift to remove the pin or the rod will be bent. If the wrist pin resists removal, heat the piston crown gently and evenly with a propane torch until the pin can be pushed out.*



Remove the other piston in the same manner.

7. Remove the cylinder base gasket.

Inspection

1. Oversize pistons are available in four oversizes in increments of 0.25 mm. Pistons come complete with rings, wrist pin, and circlips. The size is stamped on the piston crown. When fitting new pistons, set piston-to-cylinder wall clearance to 0.025–0.050 mm (0.001–0.002 in.)

2. Check the connecting rods for a bent condition. This can be accomplished with two small rectangular blocks of metal of equal thickness. Insert the wrist pins into the rods, and position

Cylinder and piston assembly

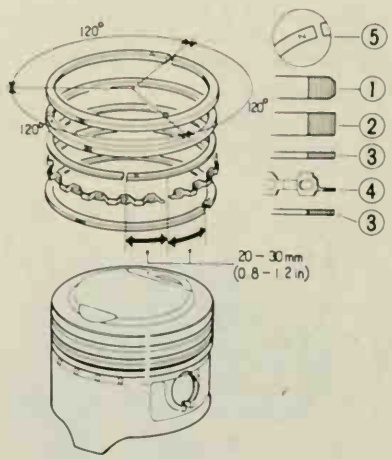
1. Cylinders
2. Cylinder base gasket
3. Piston rings
4. Pistons
5. Wrist pins
6. Wrist pin circlips
7. O-ring
8. Dowel pins

the pieces of metal beneath them on either side of the rods and resting on the crankcase. Rotate the engine so that the wrist pin rests on the blocks. Both sides of the wrist pin must contact the metal blocks or the rod is bent, and must be replaced along with the crankshaft.

3. Be sure that all oil passages in the cylinder are clear. Check the condition of the cam chain tensioner guide rollers. Replace them if the rubber is chipped, grooved, or otherwise damaged.

4. Replace the cylinder base O-ring. Check that any dowel pins or O-rings fitted to the cylinder are in their proper places before installation.

Installation



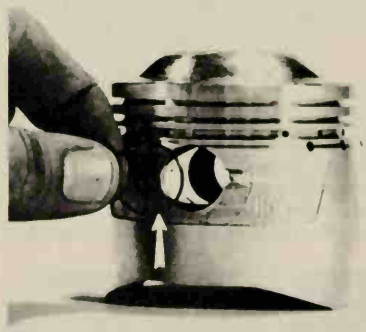
1. Before installing the rings on the piston, first note that the two compression rings are not interchangeable. The ring with beveled edges is the upper compression ring.

Also note that rings must always be installed so that the manufacturer's mark (the small letter near the end-gap) faces *up* when the rings are in place.

2. Install one rail on the piston below the oil ring groove. Install the oil rail expander in the groove, then move the lower rail into the groove. Install the upper oil rail. Install the two compression rings noting the difference between the upper and lower ones.

3. Arrange the ring end-gaps 120° apart, but do not position any end-gap of the compression rings or the oil rail expander at the very front or the very back of the piston (perpendicular or parallel to the wrist pin).

Position the end-gap of the oil ring expander 120° from the lower compression ring, then position the end-gaps of the oil rails about 45° (20-30 mm) on either side of the expander end-gap.



Piston ring installation. Be sure that rings are installed in the proper grooves (1–4) with the mark facing upward (5) and the end-gaps staggered 120° apart

4. Install one wrist pin circlip and place the piston on the connecting rod. "IN" is marked on the piston crown and must be positioned on the intake side. Oil the wrist pin and insert it. Install the other circlip.

NOTE: *Be sure to use new circlips.*

The "IN" mark must be located on the intake side when the piston is installed

When fitting the circlip, be sure that the end-gap and the cut-out in the piston do NOT align

Be sure that the circlips are properly seated. The end-gap of the circlips should point downward or positioned so that they do not align with the cutout of the wrist pin hole.

5. Check that the dowel pins are in place in the crankcase. Fit a new cylinder base gasket after any gasket compound or remains of the old gasket are removed from the crankcase mating surface.

6. Check that the piston rings are properly aligned. Lubricate the piston skirts and rings with motor oil.

7. Fit the cylinders to the studs, and hold them while pulling through the ends of the cam chain. Wire the chain ends out of the way to prevent them from falling into the engine during reassembly.

8. Have an assistant lower the cylinders slowly while you compress the piston rings with the fingers as the pistons enter the bores.

9. Push the cam chain tensioner into the housing and tighten the lockbolt. Using a new gasket, install the tensioner.

10. The remainder of assembly is the reverse of the removal procedure.

CRANKCASE COVER COMPONENTS

The following sections deal with removal, installation, and inspection procedures for those components located beneath the left and right crankcase covers.

These parts can be serviced with the engine in the frame.

Note the following points:

1. Always drain the oil before removing the right or left front crankcase covers. Place a drip pan beneath the cover before breaking the seal to catch any residue. If the cover resists removal, tap the top and sides with a plastic mallet to free it.

2. The kick-starter shaft oil seal in the right cover should be carefully checked each time the cover is removed. If the lips of the seal are torn or damaged, or if the seal leaks, remove it by prying it out of the cover with a small screwdriver or hooked tool. Take care not to use the cover itself as a leverage point without protecting it from possible damage.

To install a new seal, press it in with a block of wood which will cover the entire seal. Be sure that the seal is driven straight in until flush with the outer surface of the case, and not cocked to one side. Grease the lips of the seal before inserting any shaft into it. Where the seal must pass over splines on a shaft, ensure that there are no sharp edges from damaged splines which may tear the seal.

3. It is necessary to remove the centrifugal oil filter before the clutch housing can be removed. This requires a special wrench.

Right Crankcase Cover Components

The right crankcase cover houses the centrifugal oil filter, the clutch and primary drive, the oil pump and the gearshift linkage as well as the kick-starter return spring.

Right Crankcase Cover

REMOVAL AND INSTALLATION

1. Drain the engine oil.

2. Remove the right exhaust pipe and muffler (except CL models). Remove the footpeg stepbar.

3. Remove the kick-starter lever pinch-bolt and carefully pull the kick-starter off its splined shaft.

4. Remove the cover screws with an impact driver. Remove the cover. If stuck, tap around the mating surface with a plastic mallet. Be sure that a drip pan is beneath the cover to catch any remaining oil.

5. Installation is the reverse of the above. Note the following points:

a. Remove all traces of old gasket or gasket compound from the mating surfaces. Remove any nicks or imperfections from the mating surfaces of the cover and crankcase with an oilstone;

b. Use a new cover gasket;

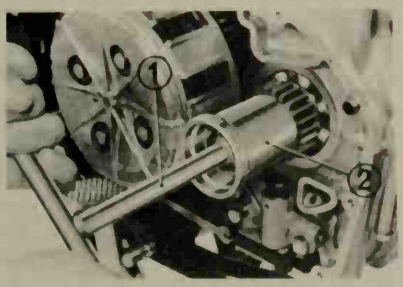
c. Be sure that the two dowel pins are in place between the cover and the crankcase before assembly;

d. Lubricate the lips of the kick-starter shaft oil seal before installing the cover;

e. When refitting the kick-starter lever, align the punch mark on the lever with that on the shaft;

f. Tighten the cover screws in a cross pattern; then secure with an impact driver.

Centrifugal Oil Filter



REMOVAL AND INSTALLATION

1. Remove the crankcase cover.

2. Remove the snap-ring from the centrifugal oil filter. Screw a 6 mm screw or bolt into the filter cap and pull off the filter cap. A crankcase cover screw is 6 mm and can be used.

3. Bend back the tabs on the lockwasher, and, holding the engine so that it does not turn over, remove the nut from the inside of the filter rotor using special Honda tool No. 07196-6390000 (500T) or No. 07086-28301 (450).

4. Remove the rotor. Clean it thoroughly in a solvent.

Removing the oil filter rotor (2) with the special wrench (1)

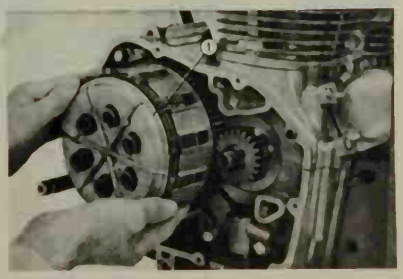
5. Installation is the reverse of the above. Replace the cap's O-ring if it is not in perfect condition. Be sure that the rotor spring washer is installed with the "OUTSIDE" marked side out. Then fit the lockwasher, secure the nut tightening it to about 35 ft lbs, and bend down the lockwasher tabs.

6. Push the filter cap into place noting that the vanes on the cap fit into the slots in the rotor. Be sure that the snap-ring is firmly seated.

Clutch and Primary Drive, Oil Pump

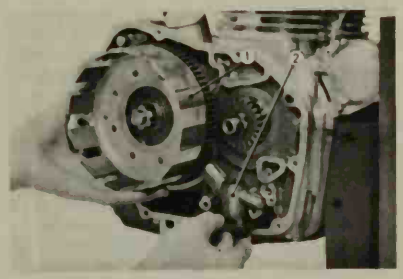
REMOVAL

The clutch housing and the oil pump must be removed together.



1. Remove the right crankcase cover.

2. Remove the centrifugal oil filter assembly.



3. Remove the clutch pressure plate bolts, washers, and clutch springs. Remove the pressure plate.

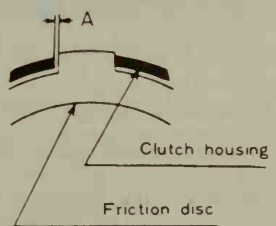
4. Remove the steel and friction plates from the clutch housing.

5. Remove the snap-ring which secures the clutch hub and remove the hub. Remove the clutch pushrod.

Removing the clutch plates

Removing the clutch housing (1) and oil pump (2) together

6. Remove the oil pump bolts; take off the clutch housing and the oil pump together. When the clutch housing is clear of its shaft, remove the oil pump plunger from the oil pump.



7. To remove the pump plunger and connecting rod from the housing, remove the circlip.

8. Remove the primary gear from the crankshaft.

INSPECTION

1. For oil pump specifications, refer to "Lubrication System."

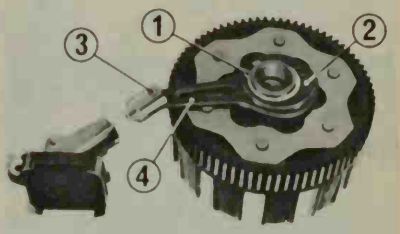
2. Clutch housing-to-plate tab backlash should not exceed 0.8 mm (0.032 in.)

Excessive clearance (A) between the clutch housing and the friction plates will cause clutch backlash

or the plates or housing should be replaced.

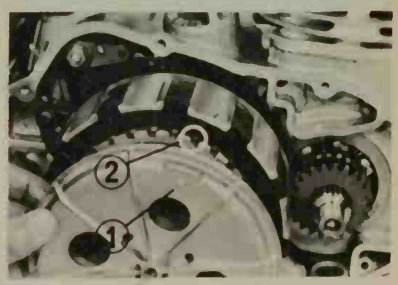
3. The clutch hub should be a close fit on its shaft. If the splines of the hub appear to be damaged, or if there is an excess of rotational movement (greater than 0.12 mm/0.005 in.), replace the hub.

INSTALLATION



1. Installation is the reverse of the removal procedure.

2. Assemble the oil pump connecting rod to the clutch housing. The shouldered side of the rod faces away from the housing. Install the side washer, fitting the tab on the side washer into the hole in the housing. Install the snap-ring.



3. Put the primary gear on the crankshaft.

4. Clean the oil pump thoroughly in a solvent. After it is completely dry, fill the pump with motor oil. Clean and install the pump filter.

5. Ensure that the hollow dowel pin fitted behind the oil pump is in place. Fit the pump plunger into the pump and install the clutch housing and oil pump.

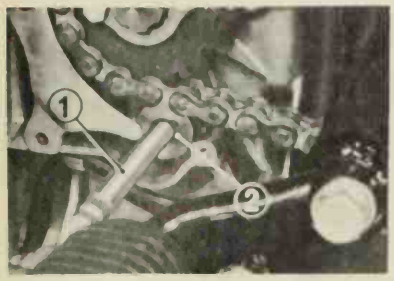
Snap-ring (1), side washer (2), plunger pin (3), and connecting rod (4)

Align the pressure plate arrow (1) with one of the cut-out splines on the hub (2)

6. Fit the clutch hub, snap-ring, plates, pushrod, pressure plate, springs, washers, and bolts. Where the pressure plate is marked with an arrow, align the arrow with one of the hub cut-out splines. Tighten the pressure plate bolts gradually in a cross pattern.

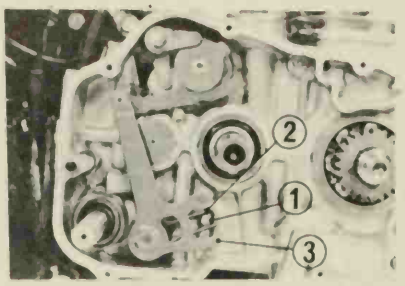
7. Install the centrifugal oil filter.

Shift Mechanism



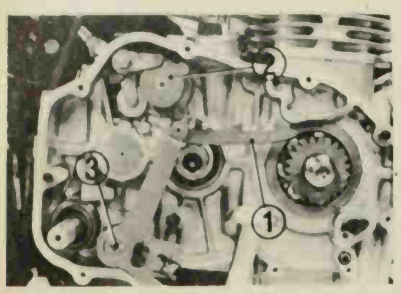
REMOVAL

The shifter shaft is fitted with an oil seal where it comes out of the left-side of the crankcase below the countershaft sprocket. If the seal leaks, it can be replaced after removal of the shifter shaft.

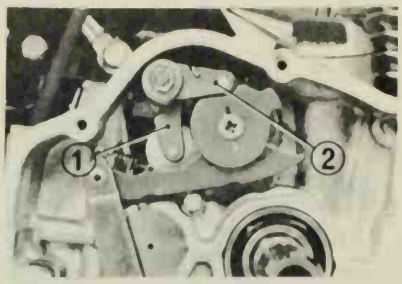


1. Remove the exhaust system (except CL models).

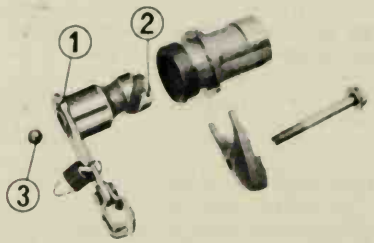
2. Remove the footpeg assembly.



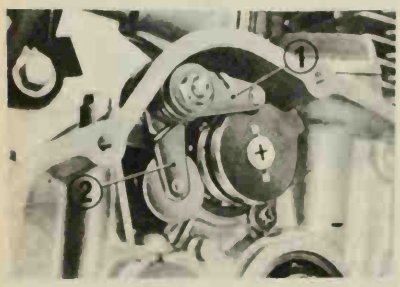
3. Drain the engine oil.



To remove the shift shaft (1), remove the snap-ring (2)



Shifter return spring pin (1), return spring (2), shift shaft (3)



Gearshift arm (1), shift drum (2), shift shaft (3)

Shift drum stopper (1) and neutral stopper (2)

Clutch lifter (1); threads (2); steel ball (3)

Neutral stopper (1); shift drum stopper (2)

4. Remove the right crankcase cover. Remove the centrifugal oil filter, clutch, and oil pump.

5. Remove the gearshift pedal.

6. Remove the rear section of the left crankcase cover.

7. Remove the snap-ring and washer from the left-side of the gearshift shaft.

8. Disengage the fingers of the shift arm from the shift drum and pull the shift arm assembly out of the crankcase.

9. Remove the nut securing the shift drum stopper and neutral stopper. Remove the stopper assembly.

10. If the shifter shaft oil seal leaks, pry it out of the crankcase. Install a new seal, driving it squarely into the case with a block of wood large enough to cover the entire seal. Grease the lips of the seal thoroughly before inserting the shifter shaft.

INSTALLATION

1. Installation is the reverse of removal.

2. Be sure that the gearshift return spring paws are positioned on either side of the pin.

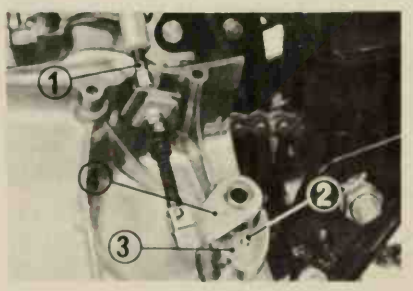
3. Check gearshifting before reassembly is complete.

Left Crankcase Cover Components

The left crankcase cover houses the alternator, starter clutch, neutral switch, countershaft sprocket, and the clutch release mechanism.

Left Crankcase Cover

REMOVAL AND INSTALLATION



1. Remove the exhaust system (CL models); remove the footpeg assembly.

2. Remove the pinch-bolt from the shift lever and pull the lever off its shaft.

3. Remove the four mounting screws from the rear cover and remove the cover.

NOTE: *Take care not to lose the steel ball from the clutch release mechanism when the cover is removed.*

4. Disconnect the clutch cable from the clutch release mechanism inside the cover.

Clutch cable (1); lockbolt (2); fixing piece (3); lifter (4)

5. Before removing the front cover, drain the engine oil. Remove three stator cover mounting screws. Remove the stator cover.

6. Disconnect the alternator wiring from the wiring harness. Disconnect the neutral switch lead from the neutral switch.

7. Remove the crankcase cover. The stator can be removed from the cover once the three mounting nuts are removed.

8. To install the covers, attach the stator to the front cover. Use a new gasket. Be sure to install the dowel pins under the cover.

Clutch Release Mechanism

1. To remove the clutch release mechanism, unscrew the adjuster lockbolt from the crankcase cover. Unhook the return spring from the inside of the cover and the release mechanism can be removed from the case.

2. Clean all parts in solvent.

3. Inspect the adjuster and lifter for damaged threads.

4. Check the dust seal for condition. If it is cracked or torn, or shows signs of age, replace it.

5. Clean the boss in the case with solvent.

6. Thoroughly grease the mechanism before installation.

Countershaft Sprocket

REMOVAL AND INSTALLATION

1. Remove the footpeg assembly and the left rear crankcase cover. Remove the sprocket protector plate if fitted.

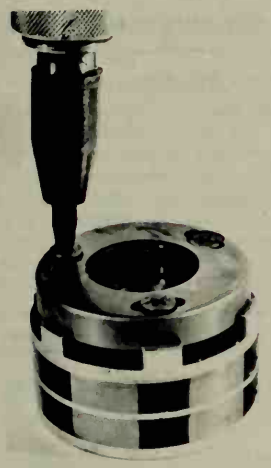
2. To remove the sprocket, remove the two bolts from the sprocket and rotate the lockplate until the tabs on the plate line up with the slots in the countershaft. Remove the lockplate.

3. Either move the rear wheel forward in the swing arm or remove the masterlink from the chain, and pull the sprocket off the countershaft.

4. When refitting the sprocket, if the masterlink has not been removed, refit the chain to the sprocket before installing the sprocket to the countershaft. Install the lockplate on the countershaft and rotate it until the holes in the sprocket line up with the holes in the lockplate. Install the two bolts and torque to 5.8–8.7 ft lbs.

Alternator and Starter Assembly

REMOVAL



1. Remove the crankcase covers and stator as previously described.

2. Remove the rotor bolt.

3. Remove the alternator rotor using the factory rotor puller. The starter clutch is removed with the rotor.

4. Remove the woodruff key from the crankshaft taper.

5. The starter clutch can be removed

Removing the starter clutch screws

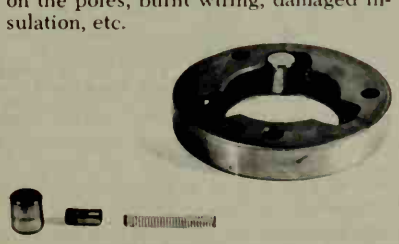
from the back of the rotor after removing the three phillips head screws. Remove the starter clutch side plate.

6. The starter motor chain can be removed by removing the sprocket retaining plate and pulling off both sprockets and the chain together.

7. Disconnect the starter motor cable at the motor; unbolt the motor from the engine, and remove the motor, tapping the shaft lightly with a plastic mallet.

INSPECTION

1. For electrical tests of the alternator rotor, stator, and starting motor, refer to "Electrical System."



2. Check that the rollers in the starter clutch are free to move. Also check that they all have the same amount of spring tension on them. If any spring feels weak in relation to the others, replace it by removing the roller, spring cap, and spring. Replace the spring and install the cap and roller.

3. Inspect the starter clutch housing for any cracks. If found defective, it must be replaced.

4. Inspect the surface of the starter sprocket where the rollers contact it. If badly scored, the sprocket and the rollers should be replaced.

5. Inspect the condition of the sprocket teeth. If they are hooked or appear to be worn badly, replace both sprockets and the chain.

6. Check the rotor and stator for signs of wear. If there has been contact between the rotor and the stator assembly, this condition must be rectified. In addition, the components should be tested to make sure that they still operate properly. Check the stator for foreign matter on the poles, burnt wiring, damaged insulation, etc.

Starter clutch components

7. Check that the stator assembly is securely mounted, and properly aligned. If the rotor has contacted the stator, check for play in the crankshaft. This condition may sometimes be caused by a bad crank bearing.

8. Remove any rust or corrosion from the crankshaft taper. Check the woodruff key for step-wear.

9. Check that the rotor has little or no run-out as it turns. If run-out exists, determine the cause.

10. If scoring on either the rotor or the stator components is severe, the part(s) should be replaced.

INSTALLATION

1. Mount the starter motor on the front of the engine with the two mounting bolts.

2. Install the starter motor chain and the two sprockets at the same time. Install the starter sprocket retaining plate.

3. Mount the starter clutch on the rotor with the three screws. Be sure to install the side plate between the rotor and the clutch.

4. Install the woodruff key in the crankshaft and install the rotor lining up the slot in the rotor with the key in the crankshaft. Draw the rotor down on the crankshaft with the rotor bolt; never strike the rotor as this may affect the magnets.

5. Install the stator in the crankcase cover, then install the cover using a new gasket. Check that the rotor does not come in contact with the stator as the engine turns over. Install the stator cover and the rear cover.

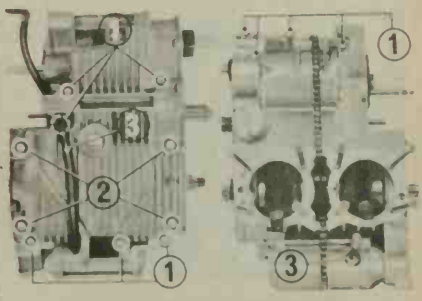
LOWER END AND TRANSMISSION

The following section deals with service to the transmission, shift drum assembly, kick-starter, and crankshaft.

Engine removal is required. If only the transmission needs service, the top end may remain in place. If removal of the crankshaft is required, the top end assembly must be removed first.

Splitting the Crankcases

1. Remove the engine from the frame.

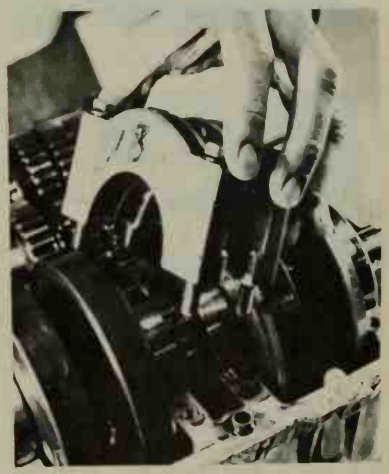


2. Remove the left and right crankcase covers and the components therein: alternator and starter, starter sprockets, countershaft sprocket, centrifugal oil filter, clutch, oil pump and primary gear, gearshift shaft, drum stoppers, etc. Refer to the preceding sections for procedures.

3. Remove the kick-starter shaft return spring.

4. If the crankshaft must be removed, remove the cylinder head, cylinder, and pistons.

5. Remove the crankcase bolts on the top case half. Turn the engine over so that the crankcase bolts on the lower case half are accessible.

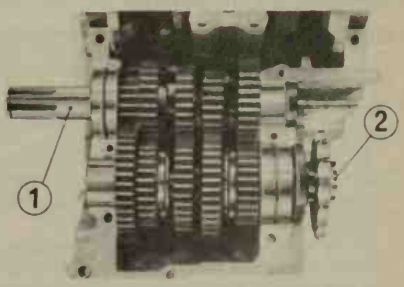


6. Remove the crankcase bolts. Remove the lower crankcase half. If it is stuck, tap the front and back of the lower

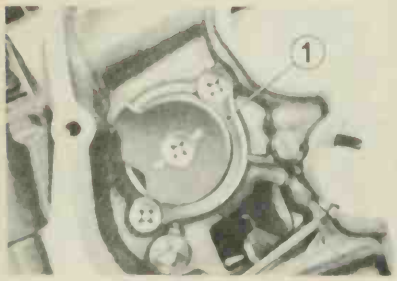
Crankcase bolts: (1) 6 mm; (2) 8 mm

case at the mating surface with a plastic mallet to free it.

7. To remove the crankshaft, remove the center main bearing cap bolts. Remove the bearing cap, noting that the cap should be reinstalled with the correct side facing forward. The cap is marked for location ("F" for forward) on late models.

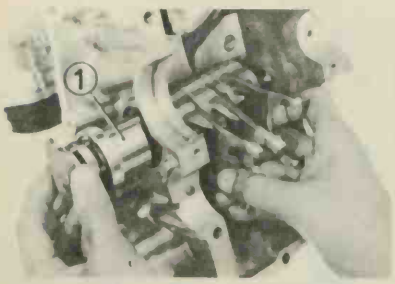


Removing the center main bearing cap

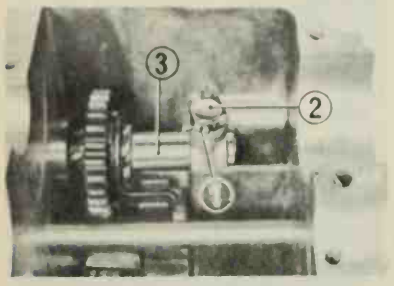


8. Carefully lift out the crankshaft.

9. Inspection of the transmission gears should be made with the gears in place. If removal is necessary, carefully lift out the gear clusters and shafts complete. Do not disassemble the shafts unless necessary. All circlips must be replaced once they are removed. Lay out each bearing, gear, thrust washer, and circlip in the order removed.



10. 4-speed: To remove the shift drum, remove the shift fork pin clip from each shift fork. Use a magnetic-tipped screwdriver or the like to remove each guide



Mainshaft (1); countershaft (2)

Shift drum bearing retaining plate (1)

Removing the shift drum (1)

Kick-starter lockplate (1), bolt (2), shaft (3)

pin. Remove the neutral stopper plunger bolt from the top of the upper case half. Remove the shift drum from the right-side and remove the shift forks.

11. 5-speed: To remove the shift drum, remove the shift drum bearing retainer plate. Remove the guide pin clip from each shift fork; remove the guide pin from each shift fork, drawing them out with a magnetic-tipped screwdriver or the like. Pull out the shift drum. Remove the forks.

12. To remove the kick-starter assembly, remove the return spring. Remove the circlip from the shaft. Bend down the locking tabs on the kick-starter shaft bolt and pull out the shaft. Remove the kick-starter gear and friction spring.

Component Inspection

CRANKCASES

1. Clean the top and bottom cases thoroughly in a solvent, taking care to remove all traces of metal particles, sludge, etc.

2. Carefully inspect the mating surfaces. Remove all traces of gasket compound. Remove any nicks or burrs on the mating surfaces with an oilstone.

3. Check that the bearing locating pins for the crankshaft and transmission shafts are not pushed into the case. Check that all bearing locating half-rings are in place

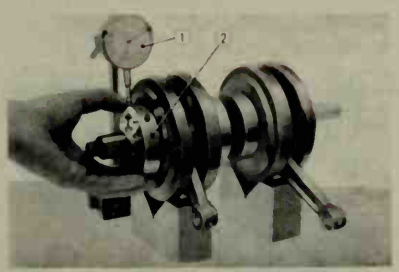
in their grooves.



CRANKSHAFT

1. Lubricate each of the crank bearings with motor oil and rotate them slowly. Bearing rotation must be smooth, effortless, and quiet; otherwise, the bearing(s) may be damaged.
2. Check the bearings for discoloration or obvious damage. The race on the outer crank bearings may be removed to check the rollers. The right-side race is secured by a circlip.
3. If a dial gauge is available, mount the crank in a set of V-blocks and check for run-out at both ends. Maximum allowable run-out is 0.1 mm (0.004 in.). This figure (run-out) will be ½ of the true indicated reading of the gauge.

Checking crankshaft run-out

4. Lubricate the big end bearing of each rod and slowly rotate the rod around the crankpin. Any noise or halting in the bearing movement may indicate that it is defective. Any vertical play indicates a worn bearing.
5. Use a feeler gauge to measure the side clearance between the rod big end and the flywheel. Standard clearance is 0.07–0.33 mm (0.0028–0.013 in.). Maximum allowable clearance is 0.5 mm (0.020 in.). Clearance in excess of this necessitates replacement of the rod and bearing.
6. Measure the radial clearance of each big end bearing by mounting a dial indicator on it and moving it up and down. Standard clearance is 0.008 mm (0.0003 in.) or less. The serviceable limit is 0.05 mm (0.002 in.). If clearance exceeds this amount, the con rod bearings must be replaced.

Checking main bearing radial clearance

7. Measure the inside diameter of the small end. Replace the rod if diameter exceeds 17.07 mm (0.672 in.).
8. Check the radial clearance of each crankshaft bearing with the dial gauge mounted directly on top of the bearing.

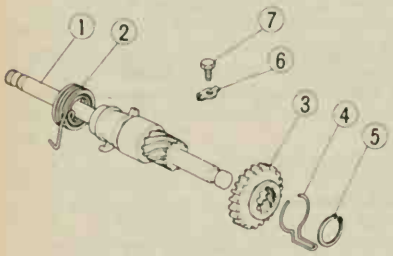
Standard radial (up and down) clearance is 0.014 mm (0.0005 in.). Replace all the bearings if the clearance of any exceeds 0.03 mm (0.0012 in.).

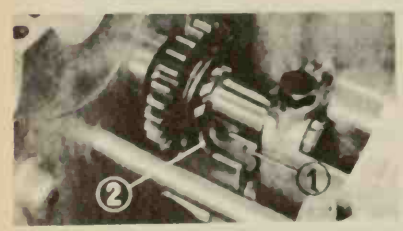
NOTE: *Special presses and jigs are necessary to disassemble or align the crankshaft. If they are not available, the crankshaft will have to be replaced in the event of damage to the rods or center main bearings.*



KICK-STARTER

1. Inspect the splines on the end of the kick-starter shaft. If they are damaged to the extent that the kick-starter lever cannot be fastened tightly to the shaft, replace it.
2. Check the condition of the circlip. Replace it if deformed or weakened.
3. Check the condition of the kick-starter return spring. If the spring cannot return the shaft quickly and hold it firmly against its stop, it should be replaced.
4. Check the friction spring for deformation.
5. Check the curved splines on the shaft and the corresponding splines on the kick-starter gear. The gear must move smoothly on the shaft. If it binds or sticks or if it can become cocked, replace the gear and shaft.
6. Check the kick-starter gear for broken or worn teeth. Replace it if damaged.

Assembling the Cases



In every case the bearings should be cleansed by squirting clean oil through them to carry away any particles of foreign matter. Bearing rotation must be perfectly smooth. If the rotation is halting, this is a sign that some particles are trapped in the bearing.

1. Fit the kick-starter shaft assembly, using a new lockwasher for the bolt. The friction spring fits into the groove in the upper case half.
2. The shift forks are marked for position: "R," "C," and "L."

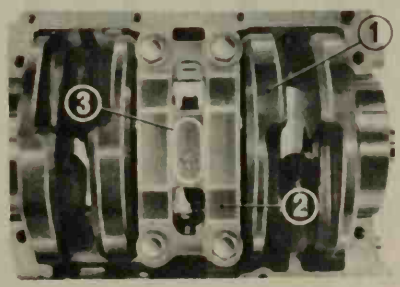
Shift forks installed (4-speed)

Shift drum assembly

1. Gearshift fork, right
2. Gearshift fork, left
3. Gearshift fork, center
4. Gearshift fork guide pins
5. Guide pin clips
6. Shift drum
7. Shift drum stopper plate
8. Stopper cam
9. Shift drum pins
10. Shift drum stopper
11. Stopper spring
12. Neutral stopper spring
13. Stopper collar
14. Neutral stopper
15. Bearing retainer plate
16. Washer
17. Ball bearing
18. Stud
19. Retainer screws
20. Stopper screw
21. Stud nut
22. Dowel pin

3. Install the shift drum, slipping it through the shift forks. Insert the guide pins, and the guide pin clips. Refer to the illustrations showing correct pin clip positions. Install the bearing retainer plate (5-speed), or the neutral stopper plunger (4-speed). Lubricate the shift drum assembly.



4. Carefully fit the crankshaft into the case. Note the bearing locating pins and the corresponding slots. Each of the bearings must be properly seated. There is no need to force the bearings into place. Line up the locators and install the crank. Lubricate the crank bearings with clean motor oil.

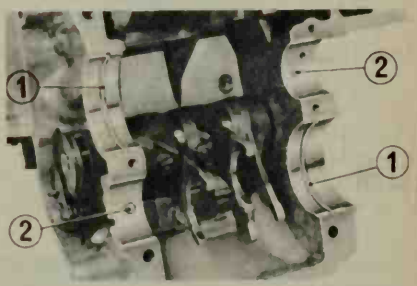
Fit the center main bearing cap, proper end forward, and tighten the bolts in a cross pattern to 18–25 ft lbs.

5. Install the gear clusters, engaging the shift forks with their proper gears as the clusters are fitted.

Crank bearings are fitted with pins which must be seated in the cut-outs in the crankcase

Where applicable, the main bearing cap must be installed with the arrow pointing toward the front of the engine

Be sure that the shaft bearings are properly located either by the locating pins or the locating rings. The needle bearing with the oil groove is installed on the countershaft, and the bearing without the groove on the mainshaft (unloaded sides).



6. Lubricate the transmission gears and bearings and check for smooth operation.

7. Fit a new countershaft oil seal and mainshaft oil seal.

8. Apply gasket compound to the mating surface of the upper case. An excess of compound will run down into the cases when they are mated.

Check that the oil passage dowel pins are in place on the left-side of the upper case. Fit the lower case. Install the bolts and tighten them in a cross pattern starting with those closest to the center. The cases should be mated all the way around prior to tightening the bolts. Do not attempt to force the cases together.

10. The remainder of the procedure is the reverse of disassembly.

Be sure that the locating pins and rings for the transmission shaft bearings are in place

Engine Torque Specifications

Part	Torque (ft lbs)

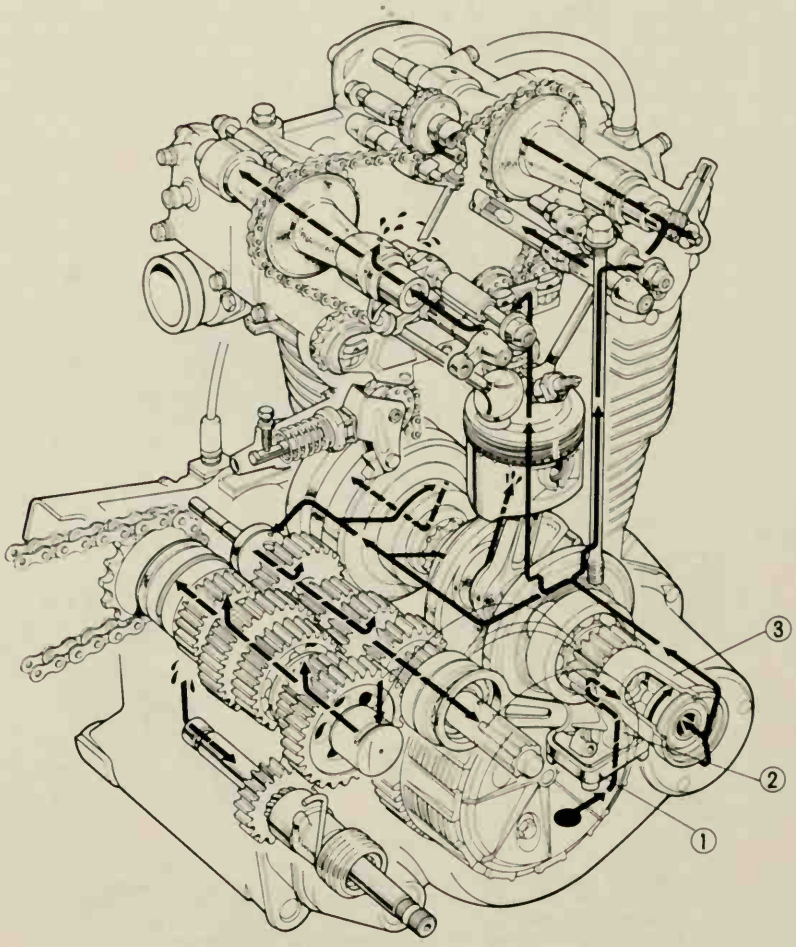
LUBRICATION SYSTEM

Honda 450 and 500 models have the same type of lubrication system: a wet-sump engine with plunger oil pump.

The oil pump consists of a body incorporating steel ball(s) as check valves, and a plunger whose movement in the housing alternately sucks in and pumps out oil. The plunger is driven by a connecting rod off the clutch housing.



Oil in the crankcase is sucked up by the oil pump, passing through a wire mesh filter screen to remove any large bits of foreign matter before it enters the pump body. From the pump, the oil is passed through a centrifugal oil filter mounted on the crankshaft. The rotation of the centrifugal oil filter rotor forces any particles in the oil against the rotor walls while the clean oil passes out and is forced through the crankcase, to lubricate the pistons and lower end, and up along the cylinder studs to lubricate the cams and valve gear.

Cross-section of 450 oil pump

1. Plunger
2. Steel ball
3. Ball seat
4. Ball stopper
5. Rubber seat

Additional oil is pumped through the transmission shafts, all of it eventually returning to the crankcase sump where the cycle is repeated.

Lubrication system: (1) pump filter screen, (2) oil pump, (3) centrifugal oil filter

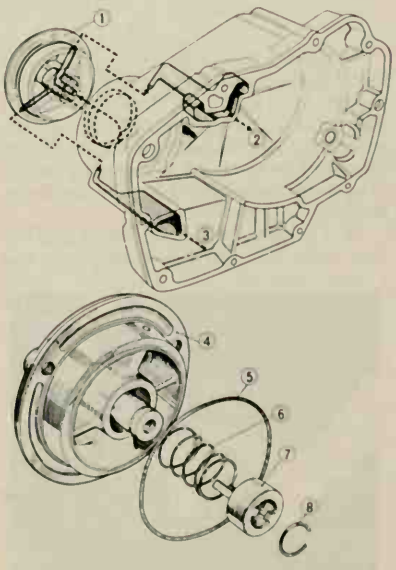
OIL PUMP

The oil pump was changed beginning with K3-model 450s. The early-type uses a steel body and an alloy plunger. The later-type pump has an alloy body with a steel plunger.

In addition, the later pump has a bore some 3 mm larger than the earlier type. The new pump can be fitted to older machines with no modifications.

Removal

To remove the oil pump, drain the oil, remove the right exhaust system (CB models), the right crankcase cover, and the centrifugal oil filter; the clutch and oil pump are removed together.



Inspection

1. Clean the centrifugal oil filter rotor in solvent.
2. Check that the oil guide piece on the centrifugal filter cover can move freely.

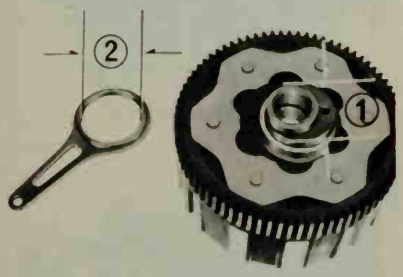
New style oil pump (left) has an alloy body and steel plunger

3. The O-ring on the cover must be in good condition. If it is not, replace it.
4. Remove the filter screen from the bottom of the oil pump and clean it thoroughly in solvent and blow dry.
5. Clean the oil pump body in clean motor oil.
6. Check the pump plunger and the bore of the pump for scoring or wear marks. Replace pump and plunger if any

Centrifugal oil filter cover assembly

1. Oil filter cover
2. Oil passage to crankcase
3. Oil passage from sump
4. Oil filter cover
5. O-ring
6. Oil guide spring
7. Oil guide
8. Stop-ring

defects are noted on the plunger or the pump bore.



7. With a micrometer, measure the diameter of the plunger and the diameter of the pump bore, and subtract the two values.

Standard clearances are 0.030–0.054 mm/0.0010–0.0030 in. (500) and 0.02–0.063 mm/0.0010–0.0025 in. (450).

Replace both plunger and body if clearance exceeds 0.2 mm/0.0079 in. (500) or 0.17 mm/0.0067 in. (450).

8. Remove the snap-ring from the clutch housing and remove the connecting rod and thrust washer.

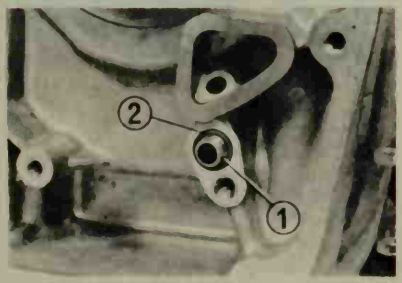
9. To remove the plunger from the rod, push out the pin.

Check the clearance between the rod (2) and the clutch housing (1)

10. Check the inner surface of the connecting rod big end for wear or galling, and the rod mounting area on the clutch housing as well.

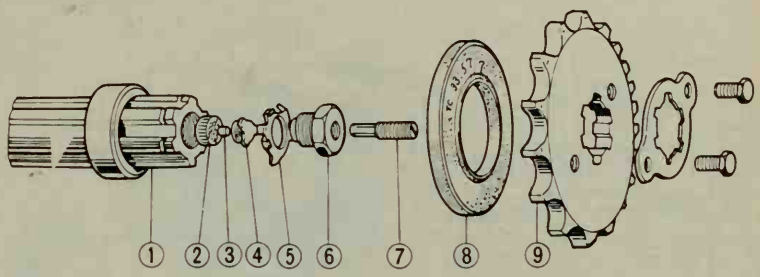
11. Measure the inside diameter of the rod big end and the outside diameter of the clutch housing area and compare the two measurements.

Standard clearance between the two is 0.025–0.075 mm/0.0010–0.0030 in.



Replace rod or housing if clearance exceeds 0.15 mm (0.0059 in.)

12. Late models: Shake the oil pump and listen for the rattle of the check valve ball(s). The ball(s) must be free in the pump body.



13. On some early models, the pump can be disassembled for cleaning or inspection by removing the pump ball stopper plug at the top. This should not be undertaken, however, except in the event of pump failure, in which case the pump will have to be replaced anyway.

Installation

1. Apply a quantity of clean motor oil to the pump bore before installation.

Be sure that the hollow dowel pin (1) and O-ring (2) are in place behind the pump

Automatic chain oiler components

1. Countershaft
2. Oil plug
3. Oil stopper
4. Rubber orifice
5. Lockwasher
6. Oiler plug
7. Adjusting screw
8. Oil seal
9. Countershaft sprocket

2. Be sure that the hollow dowel pin is in place behind the pump in the crankcase, and that a new O-ring has been fitted to the pin.

3. Install components as directed in "Engine and Transmission."

4. After installation is completed and the correct quantity of oil added, kick the engine over several times with the kickstarter (ignition off) before starting the engine.

5. Allow the engine to idle for a minute or so, then loosen the two cylinder head capnuts on the right-side of the head.

If oil seeps out, the pump is operating properly.

Tighten the head nuts to 33–40 ft lbs (500) or 20–22 ft lbs (450).

CHAIN OILER

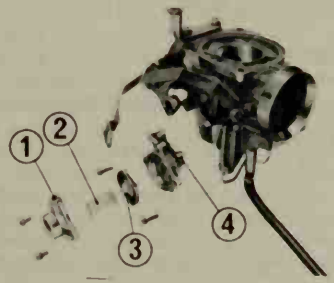
Some models are equipped with an automatic chain oiling device incorporated into the sprocket side of the countershaft. The oiler is fitted with an adjusting screw to meter the amount of oil which passes through.

The screw may be turned in (clockwise) to decrease or shut off the flow of oil; turning it counterclockwise will increase the oil flow.

Maximum oiling is achieved when the screw is turned three turns out from closed.

FUEL SYSTEM

Air Cut-Valve



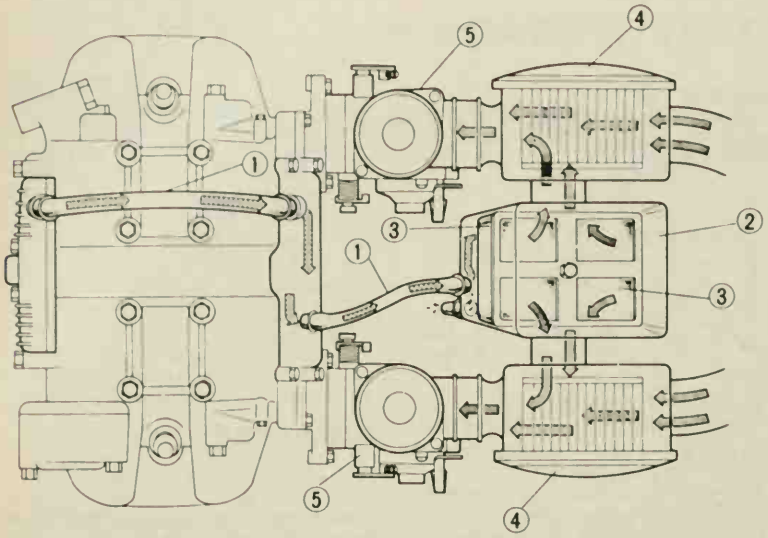
The carburetors on the 500T are fitted with a diaphragm-operated air cut-valve.

The purpose of the valve is to prevent popping in the mufflers when the throttle is suddenly closed.

When the throttle plate is closed after high-speed operation, the amount of fuel supplied to the engine is limited by the idle circuit's pilot screw. Due to the fact that the engine is still turning rapidly after the throttle is shut off, a high vacuum is created on the engine side of the throttle plate. This results in an excess of air being drawn into the engine through the slow jet.

This lean mixture may be too unbalanced to burn in the combustion chamber, so that the unburned or partially burned gases accumulate in the exhaust pipes and muffler. After the engine has turned over a number of times, the amount of fuel passing through may eventually make this mixture in the exhaust system rich enough to ignite which causes a popping in the exhaust system.

To prevent this, an air cut-valve is fitted to the slow jet. The valve takes advantage of the high vacuum condition noted above. When this condition occurs, the spring-loaded diaphragm of the valve is activated by the high vacuum and moves to obstruct the amount of air passing through the slow jet. The valve allows only a small amount of the air to pass into the carburetor intake, effectively richening the mixture so that combustion occurs in the engine, rather than in the exhaust pipes.



Air cut-valve (500T)

1. Cover
2. Spring
3. Diaphragm
4. Air cut-valve body

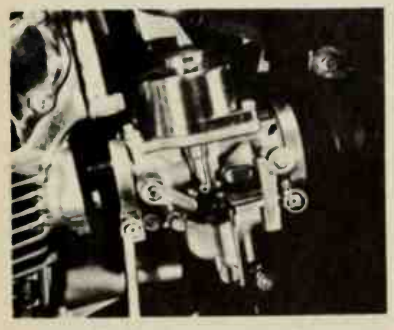
Blow-By Gas Circulator

The 500T is equipped with a recirculation system for crankcase gases. The gases are forced out of the head by the downward movement of the pistons. They are ejected into a breather box located between the two air cleaners.

A breather element separates any oil from the crankcases gases, and the oil is fed back into the crankcases. The gases are fed to the air cleaners where they join fresh air from the outside, and then are burned in the combustion chamber.

Induction and recirculation system (500T)

1. Breather tube
2. Breather box
3. Breather element
4. Air cleaners
5. Carburetors



CARBURETORS

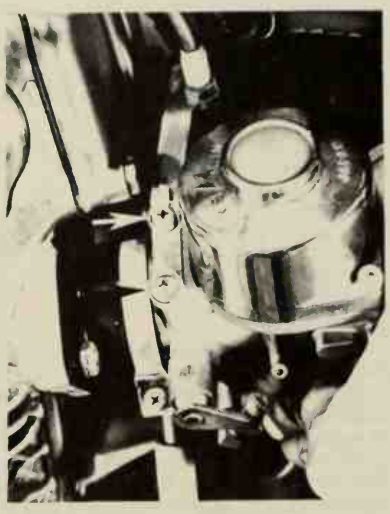
Removal

1. On CL models, remove the exhaust system.

2. Remove the left and right sidecovers.

3. Shut off the fuel petcock; disconnect the lines from the petcock. Disconnect the overflow lines from the float bowls.

Carburetor clamp screws (circles)



4. Lift the seat and remove the gas tank.

To safely remove the tank on 450 models, either drain it completely prior to removal, or obtain a four in. length of fuel line and two small clamps. Attach one clamp to the fuel tank's balance line. Disconnect the line; fit the spare length of fuel line to the tank fitting with the clamp already attached. This will prevent fuel from spilling out of the tank when the balance line is disconnected for removal.

5. Drain the carburetor float bowls, catching the gasoline in a suitable receptacle.

CAUTION: *Do not allow gasoline to spill on a hot engine.*

6. Loosen the clamps which secure the carburetors to the air cleaner and manifold hoses. Remove the air cleaners.

Cable adjuster holder screws

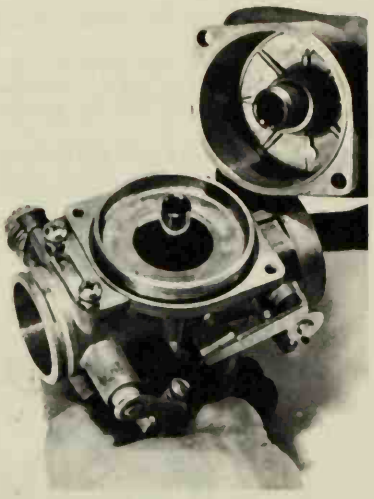
7. Disconnect the choke band from the left carburetor.

8. Pull off one of the carburetors; unscrew the cable adjuster holder from the carburetor body. Disconnect the cable from the throttle plate. Remove the remaining carb in the same manner.

Disassembly

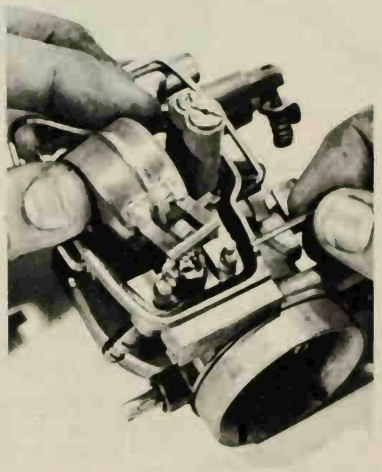
1. Have carburetor rebuild kits on hand before disassembling the carburetors.

All O-rings and gaskets should be replaced when the unit is assembled.



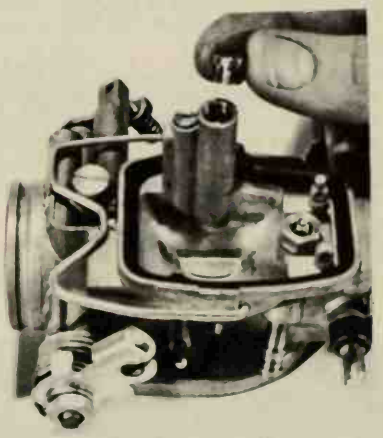
2. Remove the screws which secure the carburetor cap. Remove the cap, throttle slide, and needle. Four-speed 450s have a return spring fitted beneath the cap.

3. Remove the throttle slide gasket from the carburetor body.

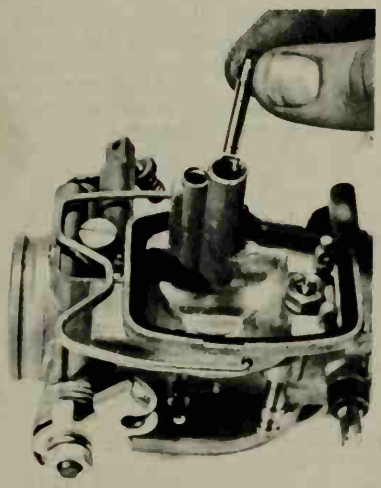


4. Pry up the float bowl retainer and remove the float bowl. Do this carefully. If it is stuck, hold the carburetor *and* float bowl firmly and tap the bowl with a plastic mallet.

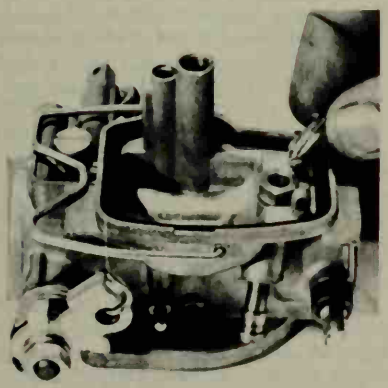
5. Pull out the pivot pin and remove the float. Unscrew and remove the main jet and the needle jet holder. Remove the needle jet.



6. Unscrew and remove the pilot jet and the slow jet.



Removing the carburetor cap



Removing the float pivot pin

Removing the main jet

Removing the needle jet holder

Removing the float needle

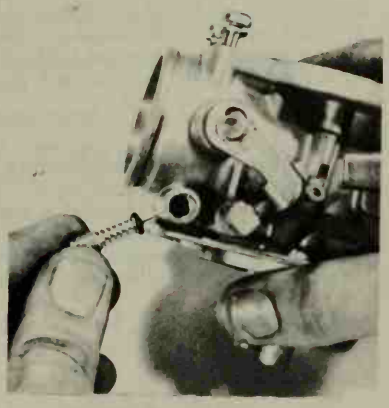
7. Remove the float needle. Unscrew the needle seat.

8. Remove the pilot screw cap (if fitted), and remove the pilot screw and spring. Use a small hooked wire to remove the pilot screw washer and O-ring.

9. 500T: Remove the two screws which secure the air cut-valve. If disassembly of the valve is required, remove the two screws which secure the valve cap; carefully remove the spring and diaphragm.

10. If disassembly of the throttle slide is required, remove the needle set screw and separate the needle and slide.

Assembly



Assembly is basically the reverse of the disassembly procedure. Note the following points:

1. Always use new gaskets and O-rings.

2. Exercise care when installing jets—they are made of soft brass and are easily damaged if overtightened.

3. If the throttle slide and needle have been disassembled, first check that both needle clips are installed in the third groove from the top. Install the needle in the slide and secure the set screw.

4. When installing the pilot screw, first assemble the spring, washer, and O-ring; screw it in very gently until it is seated, then back it off 1 turn (450) or 1½ turns (500T).

Installing the pilot screw

5. When installing the throttle slide into the carb body, engage the tab with the slot in the slide.

Installation

1. Reverse the removal procedure to install the carburetors.

2. Be sure that all connections are tight. Check that fuel lines are secured with clips, and are not contacting the carburetors except at the connections.

3. Check that the choke band is connected. Be sure that both carburetors are vertical. Check cable adjustments.

4. Before operation, turn on the fuel and check for leaks.

Carburetor Specifications

	450	500T
Setting Number	14H	75IA
Main Jet	130	145
Slow Jet	38	80
Pilot Jet	38	NA
Needle (groove from top)	3	3
Pilot Screw (turns open)	1	1½
Float Level (mm/in.)	20.0/0.79	20.0/0.79

NA Not available

ELECTRICAL SYSTEM

NOTE: *The following precautions should be observed when carrying out electrical system tests.*

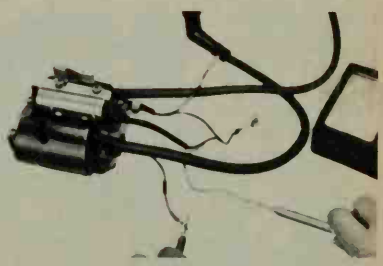
1. Be positive that battery connections are not reversed. This will burn out the rectifier almost immediately.

2. Be certain that all electrical connections are noted before disconnecting them, so that they may be reconnected properly.

3. If the battery is being charged in the motorcycle, the battery terminals *must* be disconnected, or the voltage regulator may be damaged.

4. Never disconnect the battery while the engine is running.

5. Check battery condition first, before carrying out any other charging system checks.



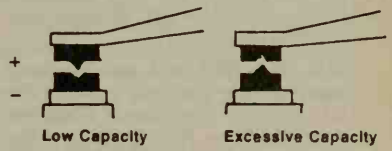
IGNITION CIRCUIT TESTS

1. Noise suppressor spark plug caps are fitted, which are designed to eliminate radio interference by means of a resistor in the cap. Sometimes the resistor breaks down, and the cap then becomes an open circuit. Remove the cap from the spark plug lead, and ground the end of the lead against the cylinder head. If a fat, blue spark is produced when the engine is kicked over, the problem was the cap. Replace it with a new one.

2. The ignition coil windings should be checked for continuity, using an ohmmeter.

a. Disconnect the two low-tension coil leads (blue or yellow and black or black/white), and check for continuity between them. This is a check of the primary winding. If there is no continuity, replace the coil;

b. Check for continuity across the black or black/white low-tension lead and the high-tension (spark plug) lead. Resistance may be very high, but continuity must exist. This checks the secondary winding;



Testing the ignition coil primary winding for continuity

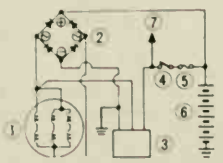
c. Even if continuity is present in the coil windings, it is possible that the coil is still defective. Replacing the coil temporarily with one which is known to be serviceable is recommended.

10. The condenser can be checked if a capacitance tester is available. Condensers should have a capacitance of approximately 0.24 mf. Checking with a "megger" (high-voltage ohmmeter) should yield a resistance of 10M ohms or better at 1,000v. Replace the condensers if they fail either test.

NOTE: *After testing, ground the condenser lead against the case to discharge it.*

As noted above, sparking at the points, or points which pit or burn rapidly would

Mounds and pits on contact breaker surfaces caused by a defective condenser



indicate a defective condenser. Bad condensers will cause mounds and matching depressions on the points.

11. If the trouble is a misfire, and the tests above do not pinpoint the problem, check the condition and operation of the automatic timing advance unit.

CHARGING CIRCUIT

1. In the event that the battery overcharges, check the battery itself, and the voltage regulator.

2. If the battery discharges quickly, or fails to hold a charge, check the battery, the regulator, rectifier, and alternator.

Charging circuit components

Voltage Regulator

A bad voltage regulator may cause the battery to go dead, or may overcharge it causing electrolyte loss, short light bulb life, etc.

The regulator is located beneath the battery box, and is rubber mounted. It can be tested with an ohmmeter, continuity tester, or ammeter.

1. If the battery goes dead, disconnect the three regulator leads (yellow, green, and black).

2. With an ohmmeter or continuity light, check for continuity between the yellow lead and the green lead. Check for continuity between the yellow lead and the motorcycle frame.

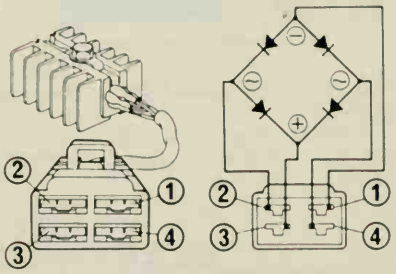
There must not be continuity in either case. If there is, the regulator must be replaced.

3. If an ammeter is available, connect it in series with the battery positive wire. Connect the regulator leads. Start and run the engine at more than 2,000 rpm. If the ammeter indicates that the battery is discharging, disconnect the regulator yellow lead and repeat the test. If the battery now shows that it is receiving a charge, the regulator must be replaced. If no change is noted, proceed with the rectifier and alternator tests which follow.

4. If the battery overcharges, check as follows:

Assuming that the battery is in good condition and *fully* charged, start the engine and connect a good voltmeter across the battery terminals. Run the engine at 4,000 rpm. The voltage across the battery should increase to between 14–15 volts, but not more. If the meter reads more than 15 volts, the regulator must be replaced.

NOTE: *This test will not be valid unless the battery is fully charged. To check this, run the engine until the voltage stabilizes, then disconnect the regulator black lead. If the voltage increases, the results of the test were valid.*



5. When mounting the regulator, be sure that the rubber dampers are in place. The regulator could be damaged by excess vibration.

Rectifier

The rectifier is located behind the battery or under the battery case.

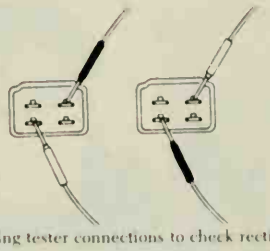
The rectifier should be checked in the event of insufficient battery charging. Tests can be carried out with a continuity light or a standard (low-voltage) ohmmeter.

CAUTION: *Do not apply high-voltage to the rectifier.*

Rectifier leads. (1) green; (2) red/white; (3) yellow; (4) pink

1. Disconnect the leads and remove the rectifier from the machine.

2. The test involves testing current flow through the rectifier in both directions. The rectifier consists of four diodes. When in working condition, a diode will pass current in one direction only.



If the diode passes current in both directions, or in neither direction, it is defective. If any of the diodes is defective, the rectifier must be replaced.

3. Connect the negative lead of the tester to the green wire, and the positive lead to the yellow, red/white, and pink wires in turn.

In each case, note whether or not there is continuity.

NOTE: *On an ohmmeter, "continuity" will be indicated by a resistance of 5–40 ohms. "No continuity," by a resistance of 100 or more ohms.*

4. Now reverse the tester connections, connecting the positive tester lead to the green wire, and the negative to each of the others in turn.

Reversing tester connections to check rectifier

In every case, the reaction of the tester must be the opposite of the first test: i.e., if the first test showed continuity between two leads, reversing the tester connections must show no continuity.

Continuity in both directions, or lack of continuity in both directions for any given pair of wires is indicative of a defective rectifier.

Alternator

The alternator should be checked in the event of low or no battery charging not attributable to the other components.

1. A dynamic output test can be carried out if a voltmeter (500T) and ammeter (450 and 500T) are available. The battery *must* be fully charged or the test may be invalid.

Hook up the voltmeter across the battery terminals (500T), disconnect the battery red/white lead, and connect it the ammeter. Connect the other side of the ammeter to the battery positive terminal.

Disconnect the black regulator lead.

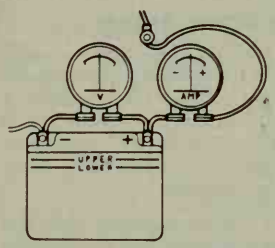
Start the engine and compare the voltmeter and ammeter readings with lights off and lights on at the given rpm as shown in the "Alternator Output" chart.

If the readings are not within 10% of the given specifications, the alternator should be replaced.

NOTE: *The alternator should not be excessively hot when this test is carried out.*

2. Using an ohmmeter or continuity tester, a static stator test can be carried out.

Disconnect the alternator wiring at the plastic connector.



3. Check for continuity between the white, the yellow, and the pink leads. Continuity must exist, or the stator assembly has a broken wire and it must be replaced.

Alternator Output

	Lights Off	Lights On (Low Beam)	Lights On (High Beam)
450			
Beginning of Charging (rpm)	1000	1500	1800
Charging Current (amps)			
3000 rpm	3.5	2.1	1.1
5000 rpm	4.5	2.9	1.9
10,000 rpm	5.7	4.0	3.2
500			
Beginning of Charging (rpm)	—	—	2800
Charging Current/Battery Voltage			
5000 rpm	—	—	1.2a/15.5v
8000 rpm	—	—	3.5a/15.5v

4. Check for continuity between the yellow lead and the stator core. If continuity exists, there is a short, and the stator must be replaced.

5. Check for broken or cracked insulation or scored or burned coil core ends.

Voltmeter and ammeter set up for alternator output test

STARTER MOTOR

1. If the starter motor spins when the button is pushed, but the engine does not, the starter clutch is defective. Refer to "Engine and Transmission," for starter clutch removal and inspection procedures.

2. If the warning lights dim when the starter button is pushed, but the engine and starter do not turn over, the battery may be too low, or the starter may be defective.

3. If nothing happens when the starter button is pushed, either the starter solenoid is defective, or there is a loose wire in the electric starter circuit.

Removal and Disassembly

1. Disconnect the lead at the starter motor.

2. Remove the alternator cover, both sections of the left crankcase cover, and disconnect the neutral switch lead.

3. Remove the alternator rotor, using either the special puller.

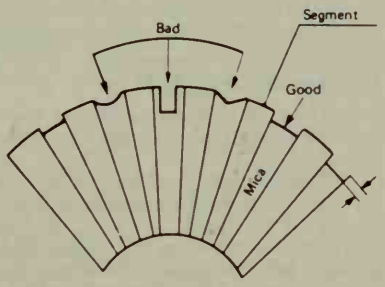
4. Remove the starter sprocket setting plate (secured by a phillips screw), and remove the two sprockets and chain together.

Starter motor end plate removal

5. Remove the two screws which secure the starter motor, and tap the starter out of the case.

6. To disassemble the starter, remove the two long phillips screws and remove the end plates.

NOTE: *Exercise caution when removing the output side end plate as this contains the reduction gears.*



7. Disconnect the starter carbon brush leads (2) and remove the brush mounting plate.

Disassembly past this point is not necessary.

Inspection

1. Use an ohmmeter or continuity tester to check the starter motor.

2. Check for continuity between each of the commutator segments. There must be continuity between all of them. If there is a dead spot, the starter must be replaced.

States of commutator condition

3. Check for continuity between the armature core and the commutator; there must be none. If continuity exists, the starter must be replaced.

4. Check for continuity between the starter lead terminal and the brushes. Continuity must exist or the starter must be replaced.

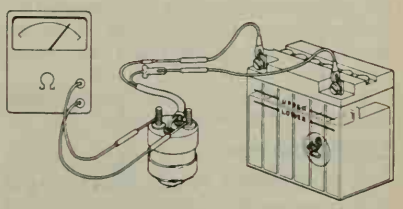
5. Measure the length of each carbon brush. Replace them if either is less than 5 mm (0.2 in.). Standard brush length (new) is 11.0–12.5 mm (0.43–0.49 in.). Replace any brush which is pitted or cracked.

6. Clean the commutator surface thoroughly with a solvent. Check that there is no scoring on the commutator surface. The mica insulation should undercut the commutator segments by at least 0.3 mm (0.012 in.). If less than this, the mica should be undercut by a qualified specialist.

7. Check the condition of the brush springs and replace them if deformed or if they will not hold the brush firmly against the commutator.

Assembly and Installation

1. Reverse the above procedures. Be sure that the output side O-rings are in place.



2. After assembling the starter, check that the armature will turn without excessive binding.

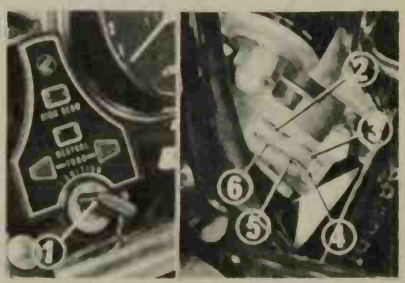
Solenoid

1. The starter solenoid can be checked by disconnecting the high-tension lead from the starter motor, and pushing the starter button. The starter switch should click when the button is pushed.

2. If it does not, use an ohmmeter or continuity light to check for continuity across the switch's primary leads (black and yellow/red 450, or yellow/red and green/red, 500T). If continuity does not exist, replace the switch.

3. Connect a fully charged 12-volt battery to the primary leads, then check for

Testing the starter solenoid



continuity across the starter switch high-tension leads. If there is no continuity, replace the switch.

ELECTRICAL SWITCHES

All electrical switches are easily checked with an ohmmeter or self-powered continuity light after disconnecting the switch leads at the plastic connectors.

Ignition Switch

1. With the key turned to the first position, check for continuity between the black and red leads. If continuity does not exist, replace the switch.

Ignition switch connections (500T)

1. Ignition switch	4. Brown
2. Brown	5. Red
3. Brown/white	6. Black

2. With the key in the first position, continuity must exist between the brown and the brown/white leads.

3. With the key in the second or "Park" position, continuity must exist between the red and brown leads.

Brake Light Switches

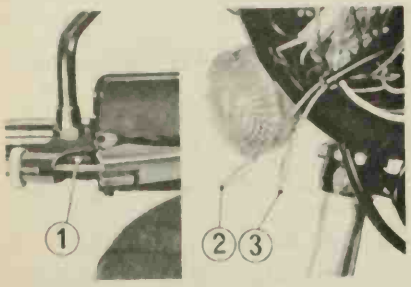
1. Check for continuity across the front brake light switch terminals. Continuity should occur when the brake lever has moved about 1 in. (25 mm), measured at the tip of the lever.

2. Check for continuity between the black and green/yellow leads to check the rear brake light switch. Continuity should occur when the brake pedal has moved about 25 mm (1 in.). This switch is adjustable.

Kill Button

1. The kill button should show no continuity between the black and the black/white leads when in either "off" position. When in the "run" position, there must be continuity.

Neutral Switch



1. Disconnect the alternator wiring at

the plastic coupler. With the transmission in Neutral, check for continuity between the lightgreen/red lead and the crankcase. There should be continuity.

2. When the transmission is in gear, there should be no continuity.

Clutch Switch

1. Late models have a clutch starter switch incorporated into the clutch lever holder to prevent operation of the electric starter when in gear with the clutch engaged. The lead connectors are in the headlight shell.

Clutch switch (1) and green and green/red clutch switch leads (2 and 3) (500T)

2. Check for continuity between the green and green/red switch leads. Continuity should exist only when the clutch is disengaged.

Silicon Diode

1. The diode is a part of the electric starter interlock circuit.

2. Check for continuity across the diode with an ohmmeter in the high reading range. Current must flow in one direction only. Current flow (continuity) in both or neither direction is indicative of a defective diode.

Horn

1. If the horn will not function, connect a 12-volt battery directly to the horn terminals. If the horn does not sound, it is defective.

2. If the horn does sound, check the horn button by disconnecting the light green lead and check for continuity between the lead and ground, which should be present when the horn button is pushed.

Dimmer Switch (500T)

1. There are five dimmer switch leads (located in the box beneath the triple clamp).

2. When switched to "Lo" beam, continuity should exist between all wires, except the blue lead.

3. When switched to "Hi" beam, there should be continuity between the black/yellow and the blue leads only.

4. When in the median position between "Lo" and "Hi" there should be continuity between all leads.

Headlight Switch (450)

1. The headlight switch lead connectors are inside the headlight shell.

2. When the headlight is switched off, there will be no continuity between the leads.

3. When the headlight is switched to "Lo" beam, there will be continuity between the yellow and white leads and between the black, brown/white, and white leads.

4. In the "Hi" beam position, there will be continuity between the yellow and white leads and between the black, blue, and brown/white leads.

Turn Signal Switch

1. When the left-hand turn signal is activated, there will be continuity between the gray lead and the orange lead.

2. When the right-hand switch is activated, continuity will exist between the gray lead and the light blue lead.

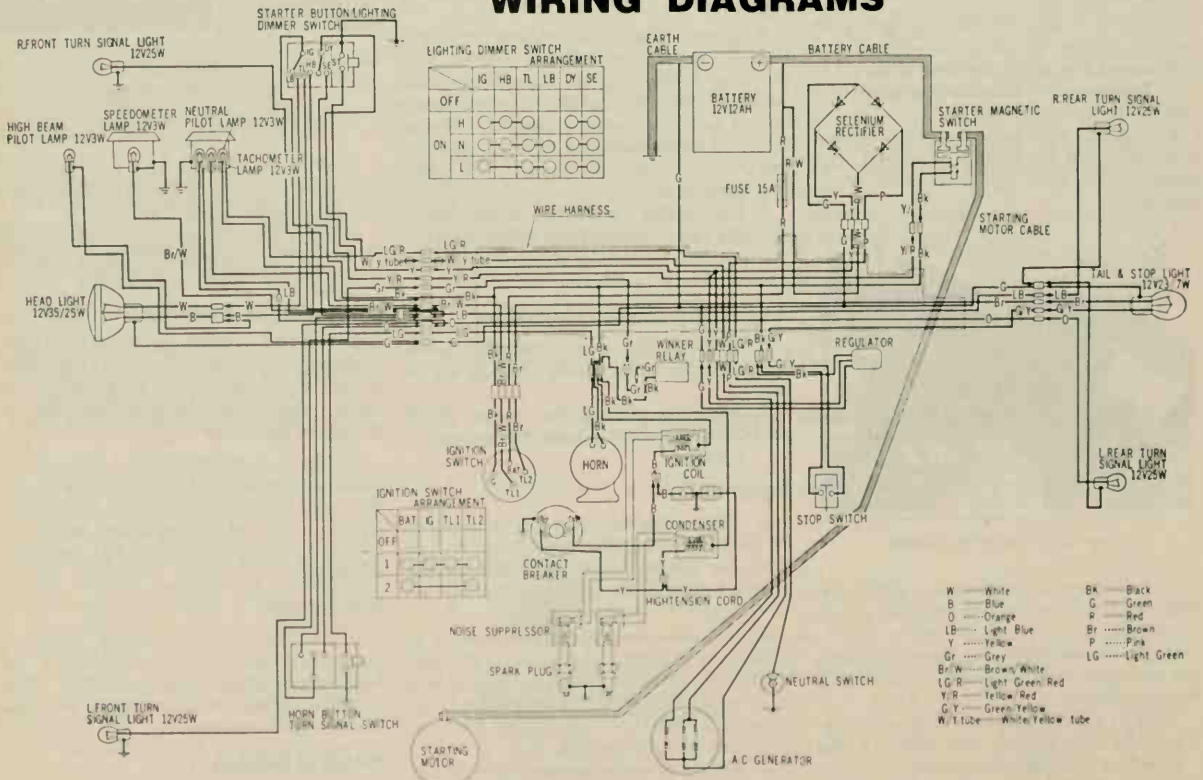
Starter Button

1. If nothing happens when the starter button is pushed, and the solenoid seems functional, check the starter button.

500T

a. Disconnect the starter button leads. When the button is free, continuity should exist between the black and black/red leads;

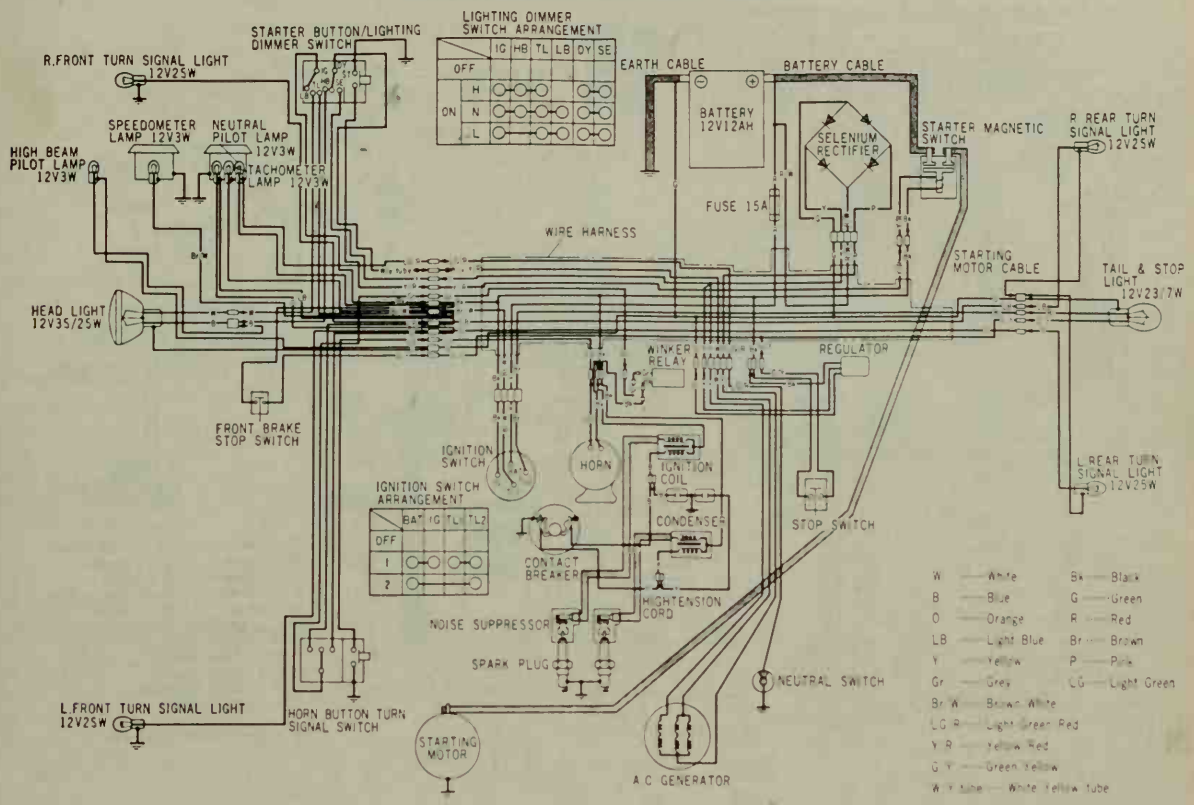
b. When the button is depressed, continuity should exist between the black and yellow/red leads.



NOTE: *The black/red lead shuts off the headlight when the starter button is pushed. This lead has an inline 7A fuse in the fuse box.*

450

a. Disconnect the yellow/red starter button lead. Check for continuity between the yellow/red switch lead and ground. Continuity should exist *only* when the starter button is pushed.



NOTE: *After separating the starter button housing, spray the button contacts with electrical connector cleaner.*

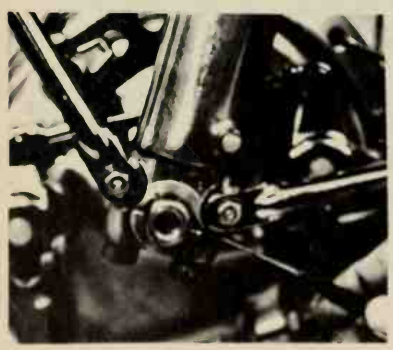
CHASSIS

WHEELS, BRAKES

Front Wheel Removal and Installation



Procedures will vary according to the type of front brake fitted.

DRUM FRONT BRAKE

1. Remove the phillips head screw securing the speedometer cable to the drive housing and disconnect the cable.
2. Loosen the locknut on the front brake cable adjuster at the handlebar lever, and screw the adjuster into the lever housing to increase the amount of slack in the cable. Remove the cotter pin from the front brake arm, pull the brake arm back by hand, and disconnect the cable. Unscrew the locknut on the lower cable adjuster (on the brake plate) until it is removed from the adjuster. Remove the cable and adjuster from the brake plate.
3. Bend back the tabs on the lockplate securing the brake anchor bolt (on the brake plate) and remove the bolt.
4. Loosen the four nuts (two on each side) securing the axle caps. Place the motorcycle on the center stand, and place a support under the engine to raise the front wheel at least 2 in. off the ground. Remove the two nuts, lockwashers, and plain washers from each of the axle caps. Remove the caps. The front wheel can now be removed.
5. To install, hold the wheel in place and install the axle caps, plain washers, lockwashers, and nuts in that order.

CAUTION: *The axle caps are machined unevenly (one side is slightly higher than the other) the high side MUST face the front. The front nuts should also be tightened first so that a small gap exists between the bottom of the fork slider and the axle cap to the rear. If in doubt which side is the high side, place a straightedge across the top of the cap, the high side should be apparent.*

6. Connect the speedometer cable to the brake plate, and secure it in place with the phillips head set screw.
7. Bolt the brake anchor to the brake plate. Be sure that the lockplate is installed correctly, the large tab on the lockplate should fit into a hole in the brake anchor. The brake anchor bolt should be secured by bending up the tabs on the lockplate against the flats on the head of the bolt.

The gap between the axle cap and the fork must be at the rear of the fork

DISC FRONT BRAKE

1. Place the motorcycle on the center stand, and place a support under the engine to raise the front wheel at least 2 in. off the ground.
2. Disconnect the speedometer cable from the speedometer drive housing after removing the phillips head set screw.
3. Remove the two nuts, plain washers, and lockwashers from each axle cap. Remove the caps. The front wheel can now be removed.

CAUTION: *Do not squeeze the brake lever when the front wheel is removed. This will force the piston in the caliper out.*

4. To install, hold the wheel in place with the speedometer drive housing facing slightly down and to the rear, and install the axle caps, plain washers, lockwashers, and nuts in that order.

CAUTION: *The axle caps are machined unevenly (one side is slightly higher than the other) the high side MUST face the front. The front bolts should also be tightened first starting on the disc side so that a small gap exists between the bottom of the fork slider and the axle cap at the rear. If in doubt which side is the high side, place a straightedge across the top of the cap, the high side should be apparent.*

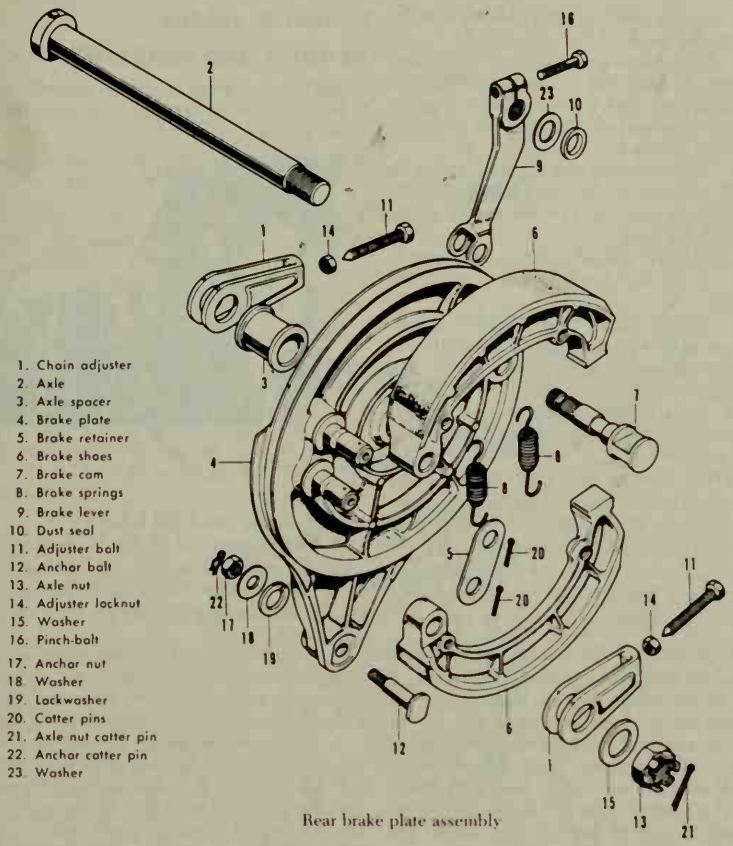
5. Connect the speedometer cable to the speedometer drive housing, and secure it in place with the phillips head set screw.

Rear Wheel Removal and Installation

1. Place the motorcycle on its center stand so that the rear wheel is off the ground.
2. Remove the mufflers (CB models only).
3. Remove the cotter pin, nut, lockwasher, and plain washer from the brake anchor bolt, and separate the brake anchor from the brake plate.
4. Remove the rear brake adjusting nut, depress the brake pedal, and separate the brake rod from the brake lever. Place the clevis pin, spring, and adjusting nut on the brake rod for safekeeping.
5. Remove the cotter pin from the rear axle nut. Remove the axle nut and flat washer.
6. Remove the masterlink from the drive chain. Place the masterlink on the end of the chain for safekeeping. If the chain doesn't have a masterlink, loosen the chain adjuster locknuts and turn the adjusters out. Move the wheel forward in the swing arm and slip the drive chain off the rear sprocket once the axle is removed. This can be done for either type of chain and does not require removal of the masterlink.

NOTE: *Place the wheel spacers on the axle in the order that they are removed, and screw the axle nut on the axle for safekeeping.*

7. To install the wheel: wrap the drive chain around the rear sprocket. Hold the wheel in place and slip the axle in place from the right-side. Be sure that the wheel spacers are in their correct locations. If the masterlink was removed, place both ends of the chain on the rear sprocket and install the masterlink with the open end of the spring clip facing opposite the direction of rotation.
8. Turn the axle nut on finger-tight. Adjust the drive chain slack; the slack, measured midway between the sprockets, should be about ¾ in.
9. Secure the brake anchor to the brake plate with a plain washer, lockwasher, nut, and a new cotter pin in that order.
10. Slip the brake cable or brake rod through the fitting in the brake lever and screw on the adjusting nut. Adjust the cable so that the brake pedal has 1 in. of free-play before the brake shoes contact the drum.
11. Tighten the axle nut to the proper torque. The proper torque can be found in the "Chassis Torque Specifications" chart. Then back the nut off until a slot in the axle nut is lined up with a hole in the axle. Secure the axle nut in place with a new cotter pin.



Drum Brake Service

All models use a single-leading shoe rear brake, while, a twin-leading shoe is used on the front. Hondas use brakes in which the lining is bonded to the brake shoe. Lining and shoe, therefore, are purchased and replaced as a single unit.

1. Inspect the lining for wear. There should be at least 0.08 in. (2.0 mm) of lining material left (measured at the linings thinnest point) or the shoes must be replaced.
2. To disassemble the brake plate, remove the cotter pin(s) and washer(s) from the brake pivot(s). Grasp each shoe and fold them toward the center of the brake plate. They may be installed in the same manner.
3. Remove the brake springs. Remove the brake lever pinch-bolt(s) and pull the lever(s) off the splined brake cam(s).

NOTE: *The plurals refer to the twin-leading shoe brakes.*

4. Push the brake cam(s) out of the brake plate from the outside using hand-pressure or if necessary by tapping with a plastic mallet. Remove the plain washer and dust seals from the brake plate.
5. Inspect the splines on the brake cam(s). These should be in good condition. Check that the brake cam(s) are not bent and that they can rotate freely in the brake plate passage. If it will not, use a fine grade of sandpaper on the camshafts and the surface of the brake plate passage.

Rear brake plate assembly

6. Clean the cam(s) thoroughly in a solvent to remove any old grease, rust, or corrosion. Use sandpaper or emery cloth to polish the cams. Clean off any residue; before reassembly, smear the cams with chassis grease.

7. On twin-leading shoe brakes, the brake plate linkage should be checked. The connecting rod is secured to each brake lever by a clevis pin and cotter pin. These pins can be removed after the cotter pins are taken off. They should be checked for wear, especially on high mileage machines, and replaced if necessary.

8. When reassembling the brake plate, note the following points:

a. Ensure that the brake cams are lubricated with chassis grease;

b. The use of new dust seals is recommended;

c. Lubricate the brake shoe pivot points with a little grease;

d. Install the shoes as on removal. Hook them together with the springs, and fold them down over the brake cam(s) and pivot(s). Install new cotter pins to the pivot points;

e. When installing the brake lever on the brake cam, be sure that the punch marks on the lever and cam align, if they are there.

Disc Brake Service

When handling disc brake fluid, observe the following cautions:

a. Brake fluid absorbs moisture very quickly, and then becomes useless. Therefore, never use fluid from an old or unsealed container;

b. Brake fluid will quickly damage paint. Place a protective cover on the gas tank;

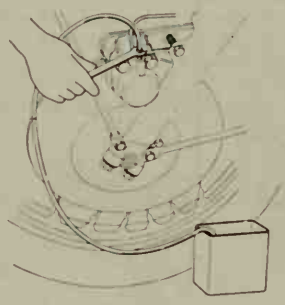
c. Use only DOT #3 brake fluid.

FLUSHING

The brake system should be flushed out every 8,000 miles, or once a year.

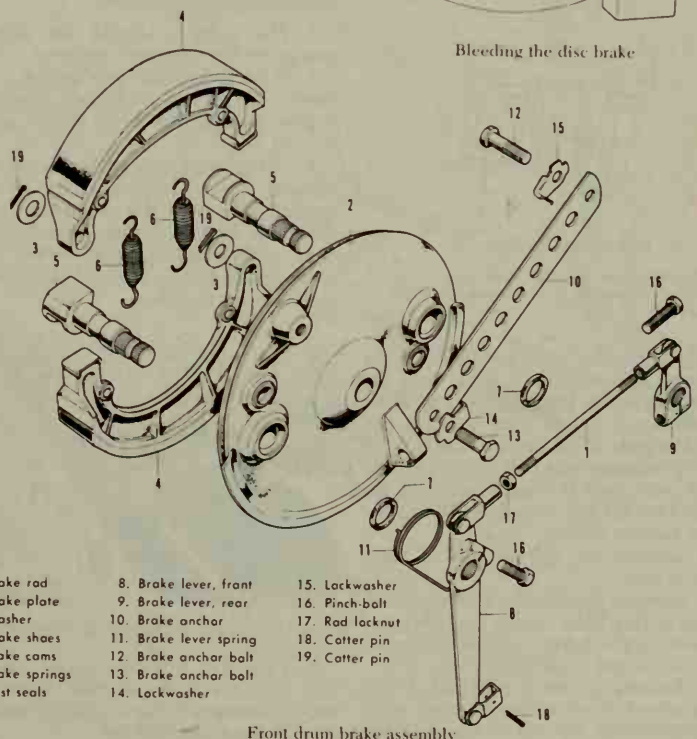
1. Attach a length of vinyl tube to the bleed screw on the brake caliper and put the other end into a small container.

2. Remove the master cylinder cap, and the diaphragm. Loosen the bleed screw about ½ turn. Pull the brake lever slowly to the handgrip, then tighten the bleed screw. Release the lever. Repeat until the master cylinder is almost empty.



3. Add new brake fluid to the master cylinder and continue squeezing and releasing the brake lever slowly until the new fluid begins to come out of the vinyl tube. Bleed the system as outlined below.

BLEEDING



1. Needed for this operation are a torque wrench, a small cup, and a vinyl tube.

2. Be sure that the reservoir is topped up. After checking the reservoir level, replace the diaphragm and cap.

3. Connect the vinyl tube to the bleed screw on the caliper, making sure that it is a tight fit; then insert the other end of the tube into a small container with several inches of brake fluid in it. Be sure

Bleeding the disc brake

Front drum brake assembly

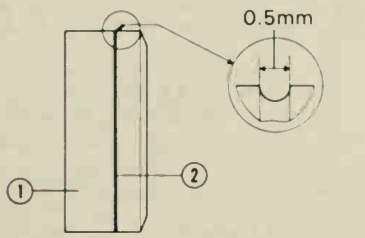
that the end of the tube is below the level of the fluid in the container.

4. Apply the brake lever *slowly* several times, then hold it ON.

5. While holding the brake lever on, loosen the bleed screw. The brake lever will be pulled toward the handgrip. Close the bleed screw BEFORE the lever bottoms out on the handgrip.

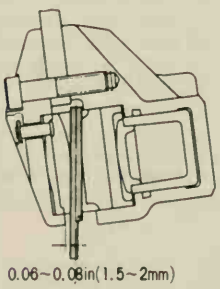
6. Repeat the procedure until the fluid issuing from the lower end of the tube is completely free of air bubbles.

NOTE: *During the operation, keep a check on the reservoir fluid level, maintaining it near its normal position.*



7. Tighten the bleed screw to 4.5–6.7 ft lbs.

8. Top up the reservoir to the level line.



PAD REPLACEMENT

1. Both pads should be replaced as a set when either pad is worn past the red limit line.

The brake pads that came as standard equipment on the early disc brake models (pre-Ks), were not marked with a limit line. To determine pad wear on these models, apply the brake and measure the clearance between the caliper and the disc with a feeler gauge as shown. When the clearance is less than 0.08 in. (2.0 mm), the pads should be replaced.

Brake pads are fitted with a red wear limit line (2)

On older disc brakes, replace the pads when caliper-to-disc clearance is less than 0.06–0.08 in. (1.5–2.0 mm)

2. Disconnect the brake line from caliper A and cover the open end with the rubber bleeder cap, which will keep out dirt or foreign matter.

3. Loosen the caliper setting bolts about ¼ turn.

4. Remove the front wheel. Now the caliper setting bolts can be removed, and the two caliper halves can be separated from the caliper pivot arm.

5. To remove pad B (the pad closest to the wheel) from caliper B, remove the cotter pin from the top of the pad. On early models the pad is held with a cotter pin on the back of the caliper.

6. To remove pad A (piston pad) from Caliper A, hold the caliper with the pad facing down, and tap the caliper lightly on top. The pad should fall out with the pad seat if fitted.

7. When installing pads, apply a small amount of silicon grease to the sides of the pad, and to the center of the back of the pad.

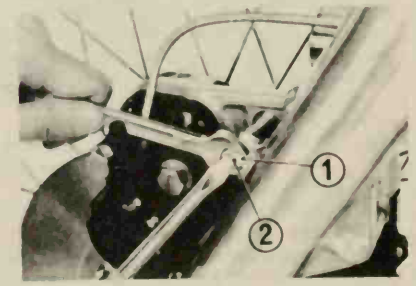
CAUTION: *Avoid getting any grease or oil on the braking surface of the pad.*

8. Install pad B into Caliper B and secure with a new cotter pin. Install pad A into caliper A with the slot in the pad facing the top of the caliper.

9. Install the two caliper halves to the caliper pivot arm and tighten the two setting bolts.

NOTE: *Fitting new pads in the place of a set which were considerably worn will cause the fluid level to rise. The excess fluid will be forced out of the inlet passage when the front wheel is mounted and the piston is forced back into the caliper.*

10. Install the front wheel taking care to locate the disc between the pads. It may be necessary to turn the caliper adjusting screw clockwise to fit the wheel. The piston pad may have to be forced back in the caliper. With the wheel in place connect the brake line and check that the setting bolts are tightened to the proper torque of 9–12 ft lbs. Adjust the caliper and bleed the system.



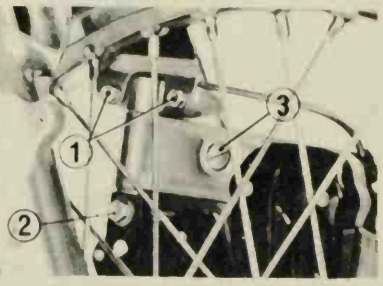
NOTE: *After installing new pads, avoid hard application of the brake for at least 50 miles.*

CALIPER ADJUSTMENT

1. The caliper should be adjusted whenever the pads are replaced.

2. Place the motorcycle on the center stand, and place a support under the engine to raise the front wheel off the ground.

3. Using a 10 mm socket, loosen the adjuster screw locknut. With a small screwdriver turn the adjusting screw clockwise until the wheel rotates freely, then rotate the adjusting screw counterclockwise until the fixed pad (pad B) just contacts the disc.



Caliper adjustment: (1) locknut, (2) adjusting screw

4. Turn the adjusting screw another ½–1 turn clockwise so that there is a small clearance between pad B and the disc. Tighten the locknut.

Caliper Assembly

REMOVAL AND DISASSEMBLY

NOTE: *A compressed air supply will be necessary to remove the piston from the caliper.*

6 mm bolts (1), 8 mm bolt (2), caliper adjusting screw (3)

1. Remove the front wheel.

2. Disconnect the hydraulic brake line from the caliper, and fit the rubber cap from the bleeder valve onto the end of the brake line to prevent dirt from entering the system.

3. Remove the caliper adjusting screw locknut from the adjusting screw and unscrew the adjusting screw from the right-side. Remove the adjusting screw spring.

4. Remove the three mounting bolts which secure the caliper pivot arm to the left fork slider. Remove the mud guard and the caliper assembly. The pivot shaft can be pulled from the pivot arm.

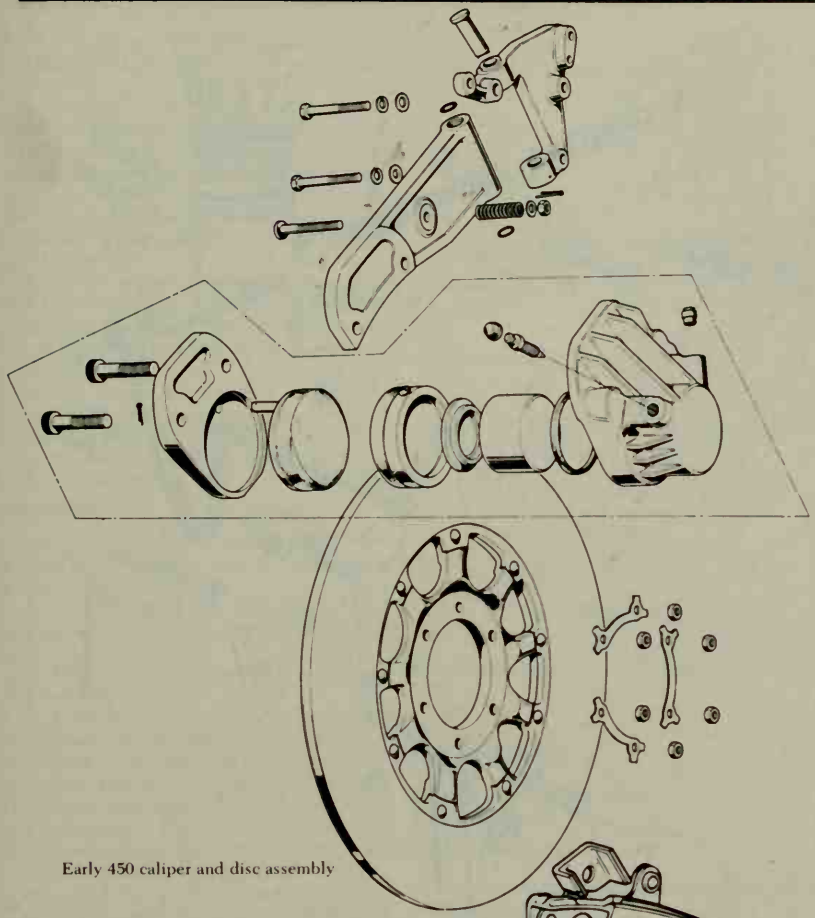
NOTE: *The two caliper halves can be removed from the pivot arm and disassembled without removing the pivot arm or the front wheel. To remove the caliper halves in this manner, see the section under "Pad Replacement."*

5. To disassemble the caliper, remove the two setting bolts from the caliper and separate the two caliper halves from the caliper pivot arm. Remove the two pads as described under "Pad Replacement."

6. Remove the piston from caliper A by blowing compressed air into the fluid inlet passage.

7. The piston seal can be removed from caliper A using a wood or plastic tool. However, note that if the cylinder walls are scored while removing the seal, the caliper half will have to be replaced.

INSPECTION



1. Check pad wear. If either pad is worn past the red limit line, it must be replaced. If no red line is present inspect the pads as described under "Pad Replacement."

2. Measure the inside diameter of the caliper cylinder bore and the outside diameter of the piston. Compare the measured value with the service limit given at the end of this section; if either part is worn beyond its service limit, it must be replaced.

3. Check the bore in caliper A for scoring. If scoring is evident, the caliper half should be replaced.

4. Check the piston for scoring; replace it if scoring is evident.

5. Check the pivot shaft for wear, also check the pivot arm for wear at the pivot

Early 450 caliper and disc assembly

points. Replace as necessary.

6. Check the condition of the two pivot shaft O-rings. If they are torn or cracked they should be replaced with new ones.

ASSEMBLY AND INSTALLATION

Since it is imperative that no dirt or foreign matter be allowed to enter the hydraulic system, assembly should take place in a clean area preferably on a sheet of white paper.

Clean and lubricate all internal brake parts with fresh DOT 3 brake fluid before assembly.

Use only "Genuine Honda Parts" when replacing any parts in the brake system.

1. Install the pivot shaft into the pivot arm. Be sure to apply some grease to the pivot points. Note that an O-ring is fitted to either side of the pivot arm.

2. Mount the pivot arm to the left fork slider with the three mounting bolts. Install the adjusting screw, spring, and locknut.

3. Install the piston seal into the caliper using a wood or plastic tool. Take care not to score the cylinder bore. Installing a new seal is recommended.

4. Install the piston into the caliper half, then install the piston pad. Install the fixed pad to caliper B and secure it with a new cotter pin.

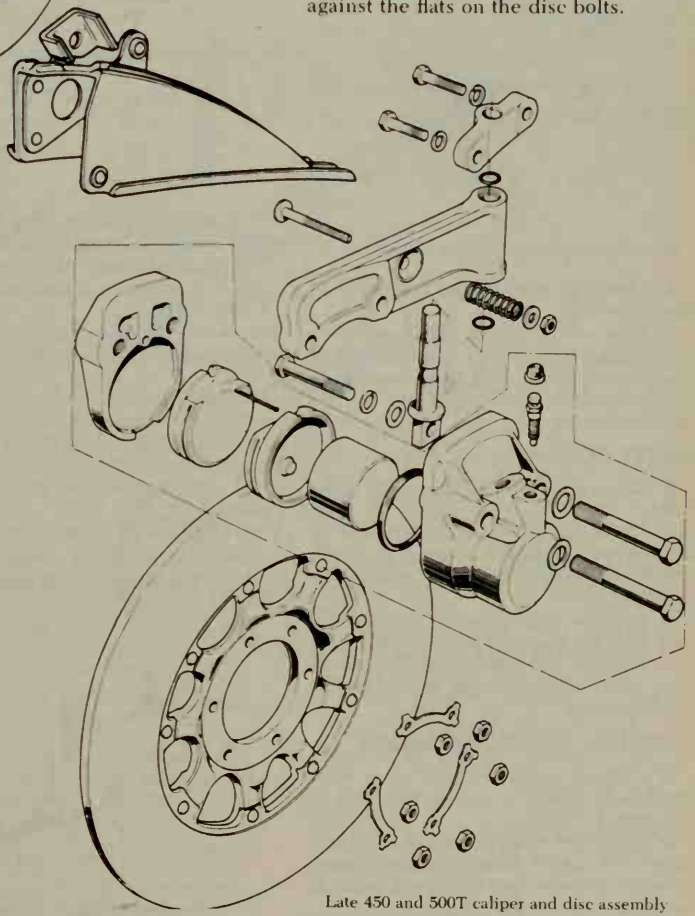
5. Install the two caliper halves to the pivot arm, and torque the setting bolts to 9–12 ft lbs.

6. Mount the front wheel. Bleed the brake as described under "Bleeding". Adjust the caliper as described under "Caliper Adjustment".

Brake Disc

1. Check the disc for warpage by attaching a dial gauge to the fork slider and its indicator on the side of the disc. Maximum warpage is 0.3 mm (0.012 in.).

Check for run-out by placing the dial gauge indicator on the edge of the disc. Maximum allowable run-out is 0.05 mm (0.002 in.).



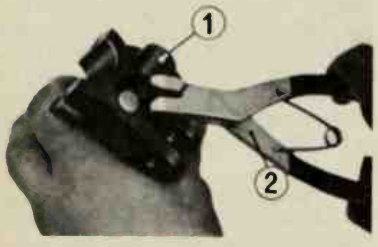
If either measurement exceeds these service limits, emove the disc from the wheel and recheck warpage. If it exceeds the specification, replace it; if it does not, suspect worn wheel bearings.

Excessive run-out can also be caused by worn bolt holes or bolts. Worn bolt holes will necessitate replacement of the disc.

2. Measure the thickness of the disc. Minimum allowable thickness is 6.0 mm (0.236 in.)

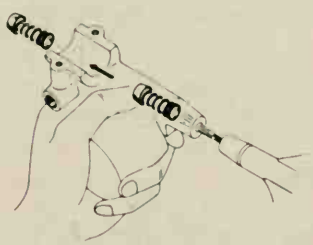
3. To remove the disc, remove the front wheel, bend down the locking tabs on the disc securing nuts, and remove the nuts.

4. When installing the disc, care should be taken to tighten the bolts evenly and gradually until the proper torque of 13–16.6 ft lbs is reached. Ensure that the locking tabs are bent up against the flats on the disc bolts.



Late 450 and 500T caliper and disc assembly

Master Cylinder



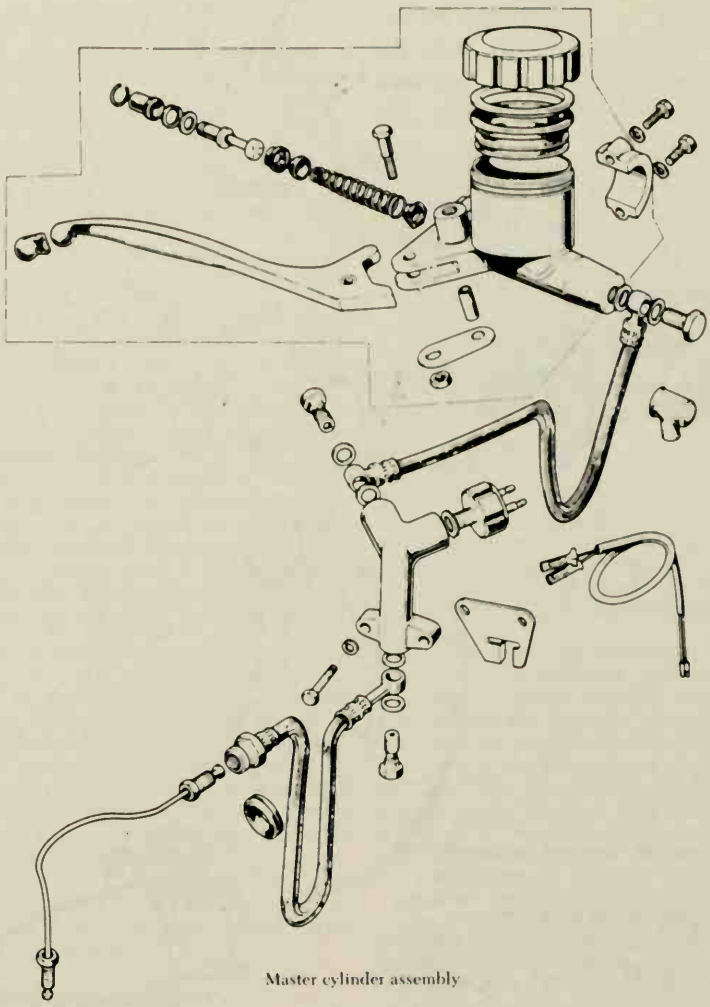
REMOVAL AND DISASSEMBLY

NOTE: *Be very careful when removing and replacing the master cylinder or refilling the reservoir. Brake fluid can remove paint or damage plastic in seconds and therefore should be handled with care.*

1. Place a cloth underneath the connection to absorb any spilled fluid and disconnect the brake line from the master cylinder. Cover the open end of the brake line with a plastic bag secured with a rubber band to prevent dirt from entering the brake system.
2. Remove the two mounting bolts and remove the master cylinder from the handlebar. Unscrew the reservoir cap and discard the brake fluid.
3. Remove the brake lever by unscrewing the pivot bolt.

Removing the master cylinder snap-ring

Removing the primary cup with compressed air



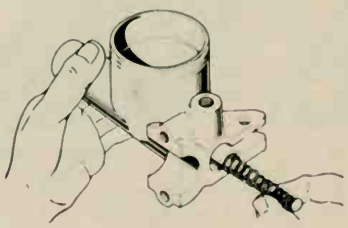
4. Carefully remove the boot and 18 mm snap-ring.
5. Remove the piston, check valve, return spring, and primary cup by blowing compressed air into the brake line fitting or by carefully pushing it out with a wooden dowel.

INSPECTION

1. Clean all components in clean brake fluid.
2. Check the master cylinder bore for signs of wear, grooves, scoring, etc.
3. Check the piston for seoring or grooves.
4. Replace the primary cup with a new item each time it is removed.
5. Replace any rubber items which show signs of wear or age, cracks, brittle condition, etc.

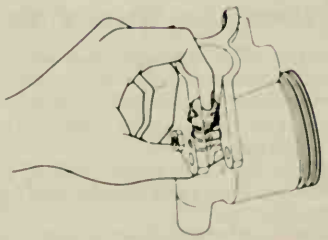
ASSEMBLY AND INSTALLATION

1. Coat all internal brake parts with fresh brake fluid, including the bore in the master cylinder.
2. Install the return spring to the check valve and install them into the master cylinder. Be sure that the check valve is facing the correct direction.



Master cylinder assembly

3. Install the primary cup after lubricating it with fresh brake fluid.



NOTE: *Make sure that the primary cup does not turn sideways during installation.*

4. Install the piston assembly and 18 mm snap-ring. Install the boot and brake lever.
5. Mount the master cylinder on the handlebar. Connect the brake line and torque the banjo bolt to 24–29 ft lbs. Fill the reservoir with fresh brake fluid and bleed the system as previously described.

NOTE: *Be sure that there is a joint washer on either side of the brake line where it is bolted to the master cylinder.*

Installing the return spring

Installing the primary cup

Wheel Bearings

Removal of the wheel bearings necessitates removing the hub oil seals on some wheels. These must be replaced with new ones upon reassembly.

DISASSEMBLY

1. Remove the wheel. For the front wheel remove the axle, spacer, and brake plate (drum brakes), or the speedometer drive housing (disc brakes). On the rear wheel, remove the brake plate and any spacers.
2. Remove any dust covers, or dust seals. Unscrew the bearing retainer, if fitted (all rear wheels, sprocket side and disc brake, disc side).
3. Pry out the oil seal. An oil seal is fitted to the disc side on disc brake wheels.

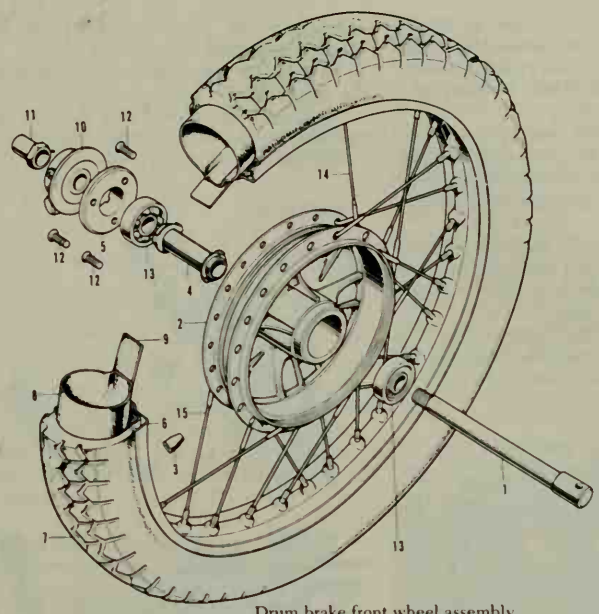
Use a small screwdriver, or, preferably, an elbow-shaped tool to remove the oil seal.

4. Remove the wheel bearings by reaching through the center of the hub with a long drift and tapping one of the bearings evenly around its circumference until it is removed. Be careful not to turn the bearing sideways in its seat on removal as there is danger of causing damage to the hub.

5. When either bearing is removed, the spacer tube can be removed from the hub. After removing the spacer tube, remove the other bearing in the same manner as the first.

NOTE: *On some models, especially high mileage machines, the hub should be heated gently with a propane torch in the vicinity of the bearing bosses to facilitate removal.*

ASSEMBLY



Assembly is in the reverse order of disassembly; however, note the following points:

1. Obtain a good grade of wheel bearing grease to lubricate the wheel bearings.

2. Pack the wheel bearings until they are completely filled.

3. Place a small amount of wheel bearing grease to the inside of the hub and drive one of the bearings into its seat. Install the retainer if so equipped. Install the spacer tube and drive the other bearing into its seat. The sealed surface of the bearing must face the outside of the hub.

NOTE: *When a bearing retainer is fitted, the bearing closest to the retainer should be installed first. Then install and tighten the retainer, spacer tube, and the other bearing.*

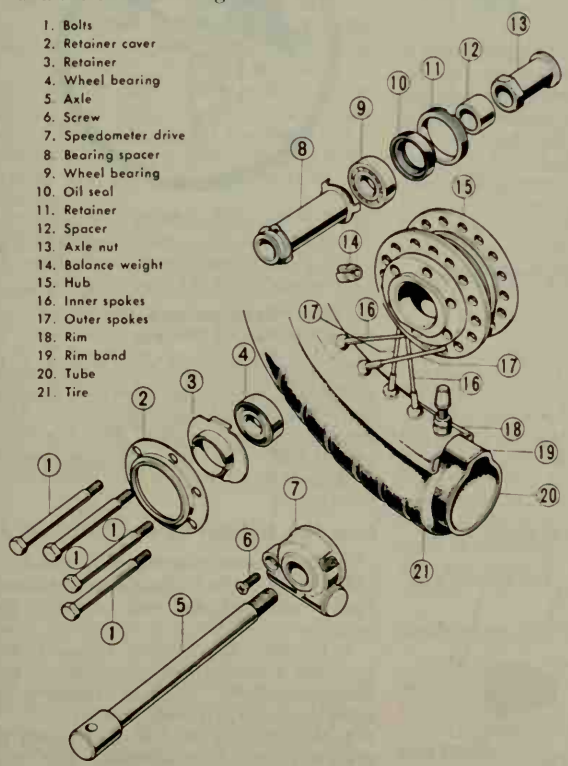
4. Replace all of the oil seals with new ones.

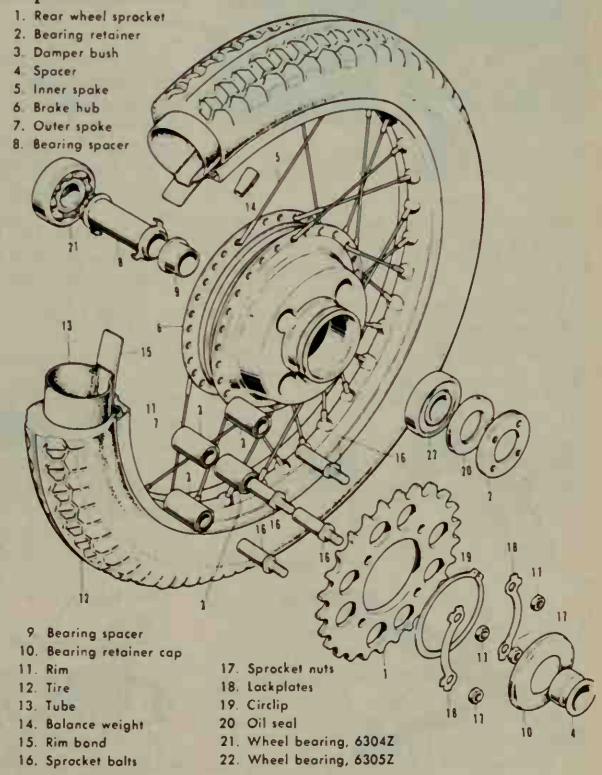
FINAL DRIVE



Chain Removal and Installation

1970 and Earlier Models

The chain can be separated and pulled off the sprockets after the master link has been removed. Threading the chain back onto the countershaft sprocket is made easier if you have an old length of chain lying around that you can hook onto the chain on the bike as it is removed. Leave the old chain draped over the sprocket so that you can hook the good chain back onto it and pull it over the sprocket when you are ready to reinstall it. Be sure to install the master link clip with the closed end facing in the direction of forward rotation of the chain.



1971 and Later Models

To remove the endless chain used on

1. Bolts
2. Retainer cover
3. Retainer
4. Wheel bearing
5. Axle
6. Screw
7. Speedometer drive
8. Bearing spacer
9. Wheel bearing
10. Oil seal
11. Retainer
12. Spacer
13. Axle nut
14. Balance weight
15. Hub
16. Inner spokes
17. Outer spokes
18. Rim
19. Rim band
20. Tube
21. Tire

Disc brake wheel assembly

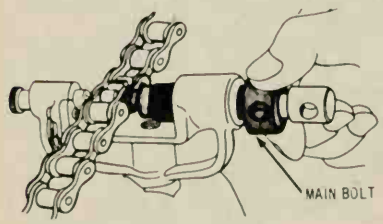
19. Circlip
20. Oil seal
21. Wheel bearing, 6304Z
22. Wheel bearing, 6305Z

Rear wheel assembly

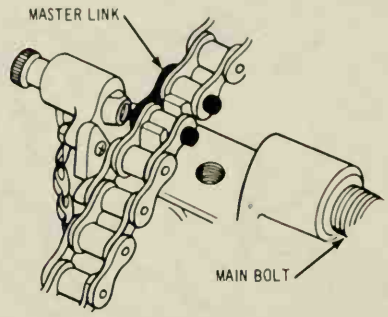
these models it is necessary to use a chain breaking tool. A heavy-duty chain breaker is available from Honda dealers, part number 07062–30050. To break the chain using this tool:

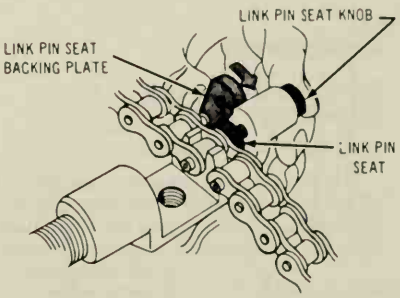


1. Grind or file the pins of the link to be removed flush with the link side plate. Do not cut the chain at the master link (identifiable by the depression in the pin centers).
2. Swing the pin seat backing plate on the chain breaker away from the pin seat and place one of the link rollers in the holding lugs of the tool.
3. Seat the main bolt against the side plate of the link and turn the link removal bolt in until the pin is driven out.

Chain breaker

1. Pin seat knob
2. Pin seat
3. Halder
4. Cotter pin
5. Main bolt
6. Link removal bolt
7. Body
8. Pin seat backing plate
9. Wedge
10. Grip
11. Guide
12. Lever

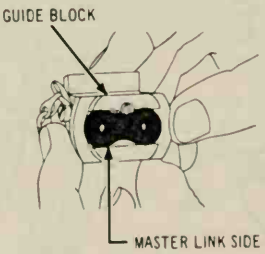


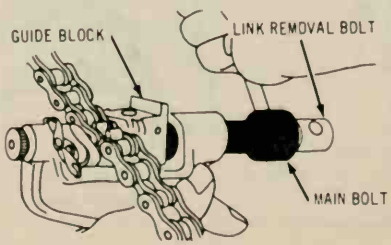


4. Place the other link roller in the holding lugs and repeat Step 3.

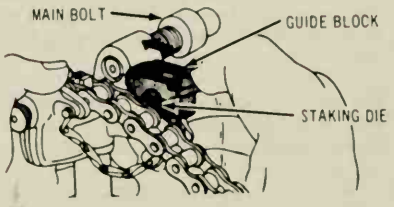
To install a new master link (replacing the chain on the motorcycle):

1. Insert the master link through the ends of the chain so that the side plate is inside (closest to the wheel).



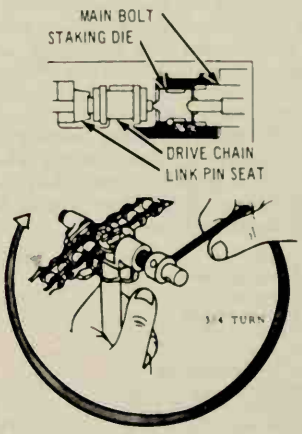


2. Place one of the master link rollers in the holding lugs of the tool with the pins facing the main bolt.
3. Push the pin seat knob in until it contacts the pin and swing the pin seat backing plate over to lock the pin seat in position.



4. Place the master link side plate in the guide block, as shown, so that the stamped letters or numbers on the plate face the surface of the guide block (facing out when installed on the chain).
5. Back out the link removal bolt until it is behind the nose of the main bolt.

CAUTION: *The link removal bolt will be damaged if it is allowed to protrude beyond the nose of the main bolt.*



6. Place the guide block in the tool with the master link side plate against the pins. Make sure that the pins are aligned with the holes in the side plate.
7. Turn the main bolt in until the pins pass through the plate and seat against the recess in the guide block.

8. Reposition the guide block so that the staking die faces the pin and the protruding shoulder of the guide block is below the side plate.
9. Turn the main bolt in until the staking die contacts the pin and check to make sure that the die is centered across the pin.
10. Turn the main bolt in an additional ¾ turn to stake the pin. Repeat Steps 8–10 for the other master link pin. Examine both pins to amke sure that they are properly staked.

CAUTION: *The main bolt must be turned no more or no less than ¾ turn. Less than ¾ turn will not secure the side plate properly, and more than ¾ turn may crack the pin.*

Sprocket Removal and Installation—All Models

To gain access to the countershaft sprocket it is only necessary to remove the left-side rear crankcase cover. The sprocket can be unbolted after the locktabs (if applicable) are bent back. Loosen or remove the chain and then remove the sprocket.

Rear Hub Damper Service

1. Remove the rear wheel assembly.
2. Remove the axle assembly. Bend back the locktabs and unbolt the sprocket.
3. Remove the circlip, separate the sprocket from the hub, and remove the damper rubbers. Replace damaged or worn dampers as a complete set.
4. Reassemble the hub and wheel in reverse order of disassembly. Use new locktabs to secure the sprocket nuts.

HANDLEBAR

Disassembly

1. On models with a disc front brake, remove the master cylinder by unscrewing the two clamp bolts.

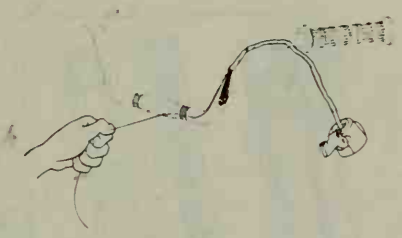
2. On models with a drum front brake, disconnect the brake cable at the lower end by loosening the locknut on the cable adjuster on the brake plate. Screw the adjusting nut back while holding the cable with a pair of pliers, this will increase the amount of free-play in the cable. Remove the cotter pin from the brake arm and pull the arm back by hand, slip the cable end pin down and out of the brake arm.

3. Remove the brake (drum brakes) and clutch cables from the handlebars by loosening the adjuster locknut and screwing the adjuster into the lever housing. Line up the slots in the adjuster and locknut with the slot in the lever housing. Pull the lever back to the handlebar and pull the cable sheath out of the adjuster as the lever is released. Remove the cable end pin from the lever.

4. To disconnect the clutch cable at the lower end, remove the gearshift lever and left rear crankcase cover. Screw the adjuster on the crankcase cover in to increase the amount of cable free-play. Disconnect the cable from the clutch release mechanism in the crankcase cover.

5. To remove the throttle cable from the twist-grip, unscrew the phillips head screws from the bottom of the lever housing. Lift up the top of the housing and disconnect the cable from the twist-grip. To replace the cable first note how it is routed, disconnect the cables from the carburetors, and route the new one in the same way as the one which was removed.

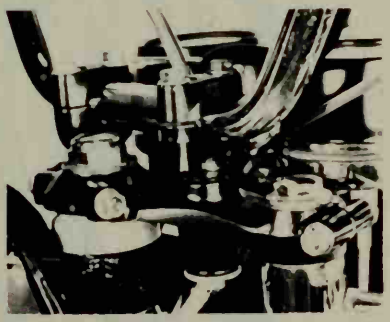
6. The electrical wiring for the horn, starter motor switch, dimmer switch, turn signals, kill switch, and the headlight switch (450 only) can be disconnected in the headlight shell (450 models) or in the wiring box on the frame downtube (500 models).



7. Remove the handlebars by unscrewing the four bolts from the handlebar holders (two bolts on each holder). Mark the front of the holders before they are removed so that they can be installed in the same direction.

8. If the lever housings are to be removed, do not pull the wiring out of the handlebars using the housing as this is likely to pull the wires out of the housing. Pull on the wires while feeding the wires in the other side.

Assembly



1. Install the electrical switches on the handlebar pulling the wires through the center of the handlebars using a lead of wire or string fastened to the longest wire.

2. Mount the handlebars on the upper triple clamp, and install the handlebar holders, with the punch mark on the handlebars aligned with the top of the lower holder.

Routing electrical wires through the handlebars

CAUTION: *The handlebar holders are machined unevenly (one side is slightly higher than the other); the high side must face the front. The high side (front) on some models can be identified by a punch mark on the top of the holder. If in doubt which side is the high side, place the holder on a straightedge, the high side should be apparent.*

The gap of the handlebar clamps should be toward the rear of the machine. The front of the clamp is fitted with a punch mark on recent models.

Tighten the front bolt first, so that the upper and lower holder are touching in the front and a small gap is left at the rear.

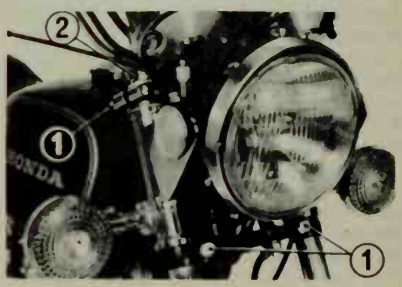
3. Connect the cables to the controls. When installing the twist-grip into the housing, be sure that the cable tensioner is correctly installed.

4. The remainder of assembly is in the reverse order ot disassembly.

5. Check the operation of all controls before riding the motorcycle.

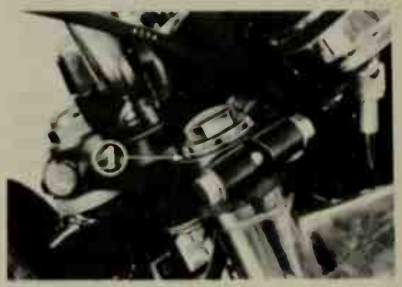
FRONT FORKS

There are several types of forks fitted to the 450 models. Early models had a sliding bushing fork with an external fork spring. Later models used a sliding bushing fork with an internal fork spring. The K5 and later models used a damper rod type fork. The removal and installation procedures are the same regardless of the type of fork fitted. Refer to the exploded view of your type fork when performing the disassembly and assembly procedures.



Removal and Installation

1. Remove the front wheel, fender, and caliper (disc brake) or brake anchor (drum brake).



2. Loosen the fork filler caps as they may be hard to loosen after the fork leg is removed. On early 450 4-speed models, the caps will have to be removed before the fork leg can pass through the upper triple clamp.

3. Loosen the pinch-bolts on the upper and lower triple clamps, and remove the fork legs, one at a time, by pulling them straight out from the bottom. Removal can be facilitated by spreading the lower triple clamp with a wedge if necessary.

4. To install the fork leg, slip it in place in the upper and lower triple clamps. On 450 4-speed models, tighten the filler caps to pull the fork into position in the upper triple clamp. On other 450 models, position the fork legs so that the top of the fork tube is flush with the top of the upper triple clamp. On the 500, the chamfered edge of the fork tube should be flush with the triple clamp surface. Tighten the lower triple clamp pinch-bolts, the filler caps, and the upper triple clamp pinch-bolts (if fitted), in that order.

Fork upper and lower triple clamp pinch-bolts (1) and filler cap (2)

The chamfered edge of the fork tube should align with the top surface of the triple clamp (500T)

5. Install the fender and the caliper or brake anchor. Install the front wheel and check the forks for proper operation. Be sure that the brake anchor bolts are properly secured with the tabs on the lockplates. Install the axle caps with the high side toward the front, and tighten the front nuts first. Adjust the brake caliper (disc brake), after assembly is complete.

Overhaul

CB450 (4-SPEED MODELS)

1. Drain the oil from the fork either from the drain plug or out the top of the fork tube. If draining the oil out the top, removing the drain plug to let air in will result in faster draining.

2. Unscrew the fork seal housing from the fork slider. If the factory tool is not available, wrap the housing in a piece of

old inner tube and fasten a hose clamp tightly around it. Grasp the fitting on the hose clamp with a pair of vise-grips, and using the vise-grips turn the fork seal housing off.

3. After the fork seal housing is unscrewed from the slider, the slider can be removed. The two fork springs and the spring seat can be removed from the bottom of the fork tube.

4. To remove the damper components from the fork tube, remove the bottom stop-ring, piston, damper valve, damper valve stop-ring, slider bushing stop-ring, and the slider bushing.

5. If the fork seal is to be replaced, remove the seal housing from the fork tube. Pry out the fork seal retainer, and the fork seal. If the fork seal is removed from the fork tube, the seal *must* be replaced. Replacing the seal as preventive maintenance when ever the fork leg is disassembled is recommended.

6. For inspection of the components of the fork leg refer to the inspection section in the following text.

7. Assembly is in the reverse order of disassembly. Install the fork seal into the fork seal housing, and replace the seal retainer. Coat the lips of the seal with fork oil before installing the housing on the fork tube. The housing should be installed from the bottom of the fork leg.

8. Coat all parts in clean fork oil before installing them on the fork tube. Install the slider bushing, slider bushing stop-ring, damper valve stop-ring, damper valve, piston, and the bottom snap-ring.

9. Install the springs in the fork tube in the order and direction that they were removed. Be sure to install the spring seat with a washer on either side between the springs.

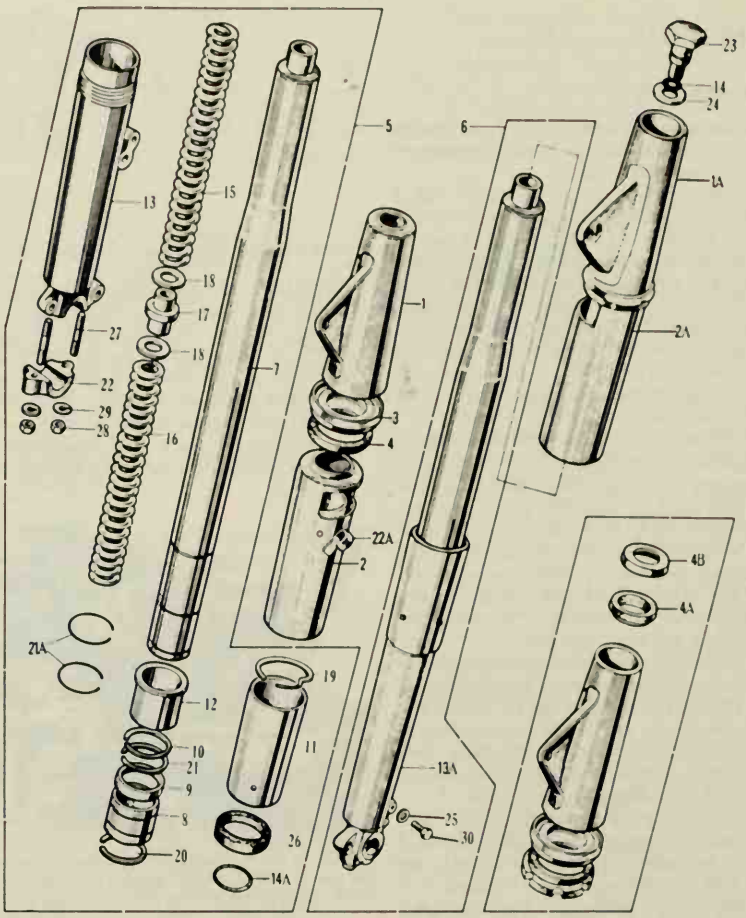
10. Install the fork tube into the slider. Fill the fork leg with the proper amount and type of oil. Refer to the "Recommended Lubricants" and "Maintenance Data" charts at the end of "Maintenance."

450 (*BEFORE 1972*)

1. Remove the fork filler cap from the top of the fork leg. Remove the spring and invert the fork over a container to drain off the oil.

2. Remove the rubber boot (if fitted). With an impact driver remove the bolt from the bottom of the slider. Remove the circlip at the top of the slider, and separate the slider from the fork tube.

3. New oil seals should always be used once the slider has been separated from the tube. Pry out the old seal with a screwdriver, but be careful not to score the slider surface.



4. Remove the circlip from the bottom of the fork leg and remove the damper components.

5. For inspection of the fork components, refer to the "Inspection" section in the following text.

6. To assemble the fork, coat the lips of the oil seal with fork oil and slip the seal on the fork tube from the bottom.

7. Install the damper components in the reverse order in which they were removed. Refer to the exploded view of your fork leg.

8. Coat the threads of the allen bolt with thread locking compound before installing it with an impact driver.

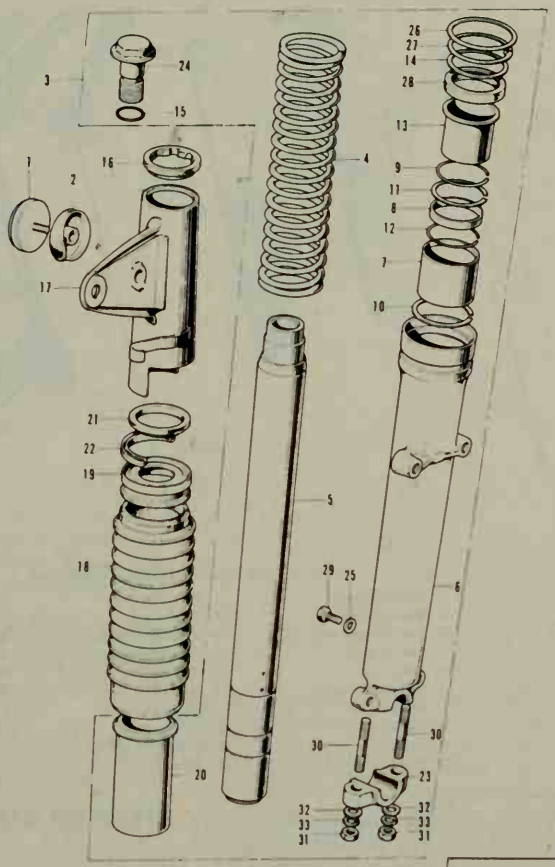
Removing the fork slider circlip

450 (*1972 AND LATER*)



1. Remove the fork filler caps and the piston rod locknuts.

2. Pull the spring out of the tube and invert the fork leg assembly over a suitable container to drain the oil.

3. Pull the rubber boot off the leg if it remained attached when the leg was removed. Remove the circlip at the top of the fork slider, and separate the fork leg and slider.

4. Pry the seal out of the fork slider, taking care not to damage the inside surface.

5. The damper assembly can be removed from the slider after unscrewing

the allen bolt that is recessed into the bottom.

6. Refer to the following "Inspection" section for inspection of the fork leg components.

7. To assemble the fork leg, coat the lips of the oil seal with grease and drive it into the top of the slider. Be sure that it is driven in far enough to allow the circlip to be refitted. If necessary, the old oil seal can be used to drive in the new one.

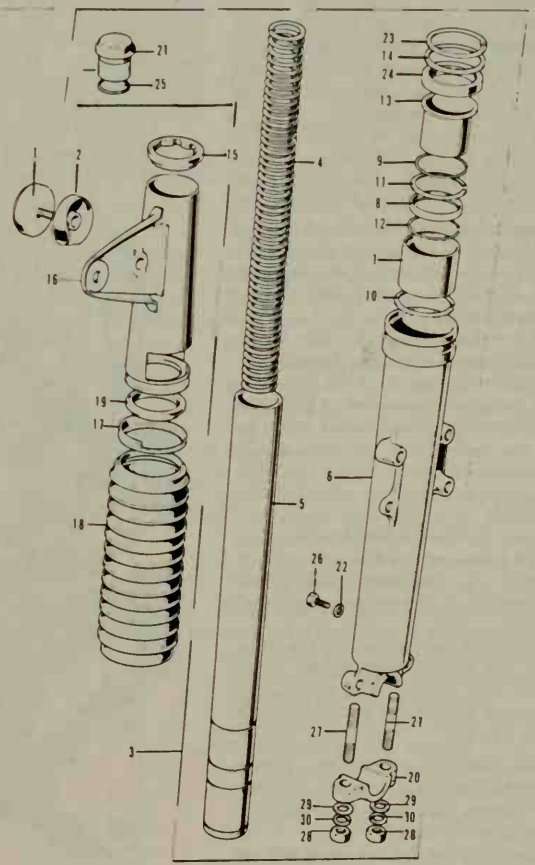
Separating the fork slider from the fork leg

8. Install the damper assembly into the slider and tighten the allen bolt with an impact driver. The threads of the allen bolt should be coated with thread locking compound before installing it.

9. Install the fork tube into the slider and refit the slider circlip.

10. Fill the fork leg with the proper amount and type of oil. Refer to the "Maintenance Data" chart at the end of "Maintenance." Tighten the filler caps after installation.

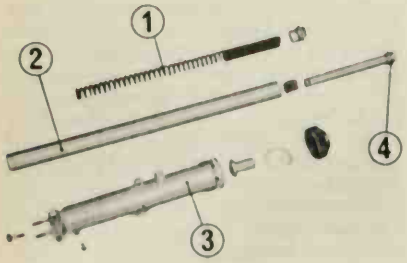
500T



The procedure is given for one fork leg but applies to both.

1. Remove the filler cap from the top of the fork leg and pour the oil into a suitable container to be disposed of. The fork spring will come out when the fork leg is turned upside down and can be removed at this time.

2. Turn the fork leg upside down and rest it on a block of hard wood. With an impact driver and the proper bit, remove the allen bolt from the bottom of the slider.



NOTE: *These bolts are installed with thread locking compound and trying to remove them without an impact driver will result in rounding the head of the bolt.*

3. When the bolt is removed from the bottom of the slider, the damper rod complete with piston ring, and the rebound spring can be removed by taking them out from the top of the fork leg.

29. Washers
30. Lockwashers

Front fork assembly (CB450K3-K4)

Fork components (CB500T)

4. The inner tube can now be pulled out of the slider. Once the inner tube is pulled out of the slider, the oil seal in the slider will have to be replaced.

5. Remove the dust cover and retainer from the top of the slider and pry out the oil seal with a hooked tool. The pin wrench from the Honda tool kit may be used by slipping the hooked end under the seal and tapping on the handle with a hammer. A strip of copper or soft metal can be placed between the top of the slider and the wrench to protect the slider.

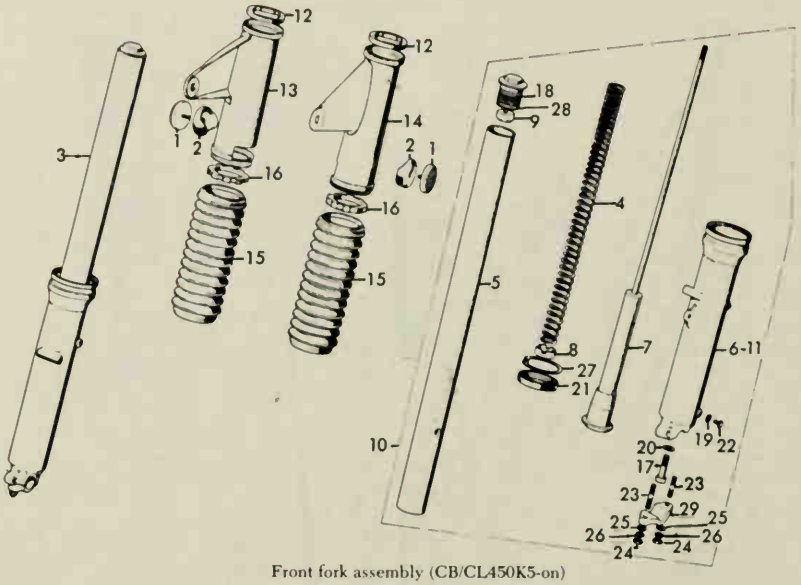
6. For inspection procedures, refer to the following "Inspection" section.

7. To assemble the fork leg, lubricate the oil seal with ATF and install it in the top of the slider. Place a block of hard wood over the seal and drive it into the slider as far as possible. Then place the old oil seal on top of the new one and drive them in until the new seal clears the snap-ring groove in the slider. Take out the old seal. Be sure that the new seal is straight in the slider. The distance from the top of the seal to the retainer groove should be the same all around the seal. Install the retainer.

8. Fit the dust seal to the fork tube, then carefully install the slider. Install the rebound spring then the damper rod from the top of the fork tube. Refit the fork spring and cap temporarily. Turn the fork upside down and install the bolt in the bottom of the slider. The threads of this bolt should be coated with thread locking compound.

9. Fit the drain plugs; be sure to install a copper washer on the drain plug.

10. Remove the cap and fill the forks with the proper amount of ATF. The specifications for your model can be found at the end of the "Maintenance." Refit the cap.



Inspection

1. Inspect the fork tubes for bends as might have been incurred in an accident. Replacement is recommended rather than attempting to straighten bent fork tubes.

2. Check that the surface of the tube on which the slider components move are smooth and free of rust or scoring. Minor rusting should be removed with fine emery cloth.

3. Check the spring condition; check that the spring heights are equal. If either spring is compressed more than 0.25 in., both should be replaced.

4. Check that the damper rod (where fitted) is straight and that all damper components are clean.

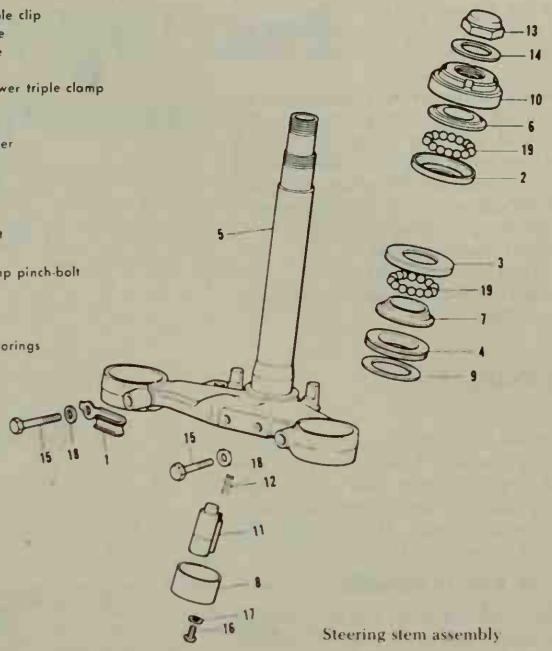
STEERING STEM ASSEMBLY

Bearing Adjustment



On models equipped with a friction steering damper, the damper should be loosened (counterclockwise) as much as possible so that it does not interfere with the bearing movement while checking or adjusting the bearing.

1. The steering stem bearings are uncaged #8 balls or ¼ in. balls. They are adjusted by means of a ring nut beneath the upper triple clamp.

Adjusting the steering head bearings

1. Speedometer cable clip
2. Upper frome race
3. Lower frome race
4. Dust seal
5. Steering stem/lower triple clamp
6. Top cone race
7. Lower cone race
8. Steering lock cover
9. Washer
10. Adjuster nut
11. Steering lock

13. Steering stem nut
14. Washer
15. Lower triple clamp pinch-bolt
16. Screw
17. Washer
18. Washer
19. Steering stem bearings

Steering stem assembly

2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender, place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The fork should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

6. To adjust the bearings, remove the upper triple clamp. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above.

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Disassembly

1. Remove the front wheel, front forks, and handlebars. If a friction steering damper is fitted, remove it by removing the two cotter pins from under the lower triple clamp, and unscrewing the damper rod and removing the friction plates.

2. Loosen the rear pinch-bolt on the triple clamp. Unscrew the steering stem nut and disconnect the speedometer and tachometer cables from their instruments. Remove the upper triple clamp.

3. Disconnect the wiring inside the headlight shell, and remove the headlight shell and the fork ears.

4. Loosen the steering stem adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race and the ball bearings from the top race.

5. Carefully pull the steering stem out from the bottom. Some of the ball bearings from the lower race will probably fall out at this time so be prepared for this.

6. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. These will have to be pried off with a chisel, therefore only remove them if necessary.

7. The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

Removing the lower frame race

New races are installed with a suitable sized bearing driver: i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

These races can also be installed using a block of hard wood of sufficient size to cover the race in place of a bearing driver.

Inspection

1. Inspect the bearing race surfaces. They must be clean and smooth. That is free from any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races. Note any roughness or ripples on the race surface. If any imperfections are noted, both the sets of races and all of the balls must be replaced.

2. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

NOTE: *Balls and races must always be replaced in a set as worn races will destroy new balls and worn balls will destroy new races.*

Installation

1. Install the dust seal washer, dust seal, and lower cone race on the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the upper race in the frame lug.

2. Embed 18 balls into the grease of the top frame lug and 19 balls into the steering stem through the frame lug and hold it in place while refitting the top cone race and threading on the adjuster nut.

4. Tighten the adjuster nut all of the way by hand, rotating the steering stem

to work the grease into the balls.

5. Tighten the adjuster nut until the steering stem turns freely, but has no play.

6. Install the fork tubes, headlight assembly, and upper triple clamp, flat washer, and steering stem nut. Check that the stem moves freely to the steering lock of its own weight when released from 5°–10° off center; if not check for:

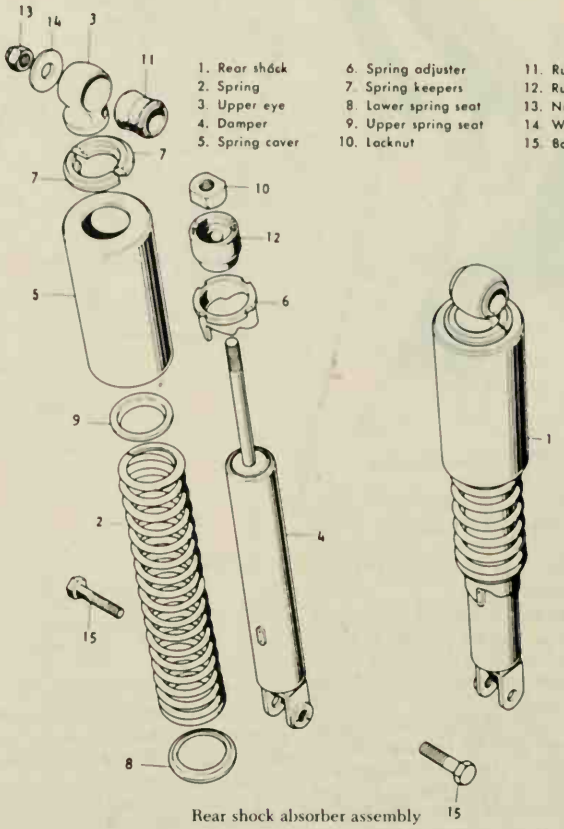
a. Steering bearings too tight;
b. Bent steering stem;
c. Worn races or balls.

7. Install the front fender, front wheel, and handlebars.

REAR SHOCKS

DeCarbon type damper units are fitted to the rear shocks. These units are filled with oil and nitrogen gas under high pressure, therefore no attempt should be made to repair them. If defective, the units must be replaced.

Removal and Installation



1. The shock absorber can be removed after the upper and lower mounting bolts and the lift bar on the right-side are removed.

2. To remove the spring, first set the spring adjustment cam on the softest position. Then compress the spring either using a spring compressor (Tool No. 07958-3290000) or by hand and have an assistant remove the spring retainers.

3. Measure the free-length of the spring, if less than 7.7 in. (195 mm) (450) or 8.1 in. (205 mm) (500T), the springs should be replaced.

4. Assembly is the reverse of disassembly. Progressively wound springs are installed with the close coils at the bottom of the shock.

5. Install the shock on the machine and check that it does not bind in operation.

Rear shock absorber assembly

SWING ARM

Inspection

1. Remove the exhaust system (CB models).

2. Remove the rear wheel, shock absorbers, and chain guard.

3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.

4. Check that the rear wheel mounting plates are parallel.

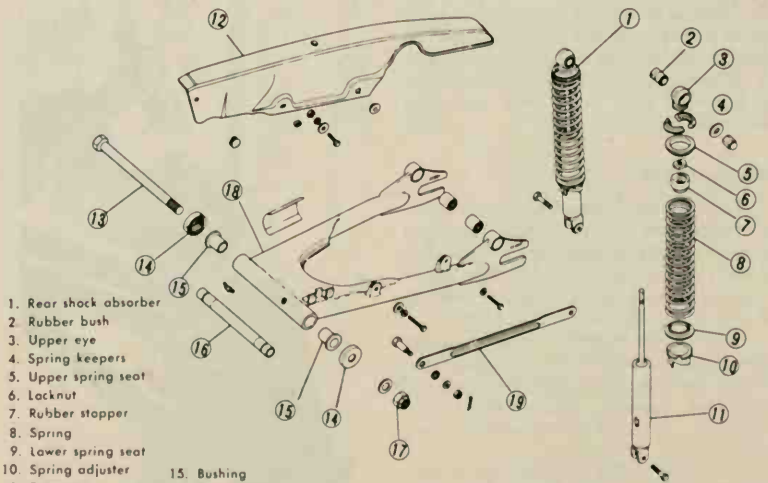
5. Grasp the legs of the swing arm and attempt to move it from side-to-side. Any noticeable side-play will indicate that the swing arm bushings need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

Removal and Installation

1. Proceed as above. Then remove the swing arm pivot bolt nut, and pull the pivot bolt out from the right-side.

2. Remove the swing arm by pulling it straight back.



3. The swing arm should be inspected for cracks or fractures, especially around the welds.

After removal of the swing arm, the dust seals and bushings can be replaced. This should be done every 10,000 miles, or more often depending on how the machine is used, or if the bushings are worn (see "Inspection").

4. Remove the bushings, tapping them out with a hammer and punch. Once the bushings are removed, they should be replaced.

5. Lubricate new bushings with a good chassis grease. Press the bushings into the swing arm, then lubricate and install the swing arm collar.

6. Install the swing arm on the machine. Grease and install the pivot bolt. After tightening the swing arm pivot bolt nut, move the swing arm up and down to ensure that movement is smooth and effortless.

Swing arm assembly (CB500T)

GENERAL INFORMATION

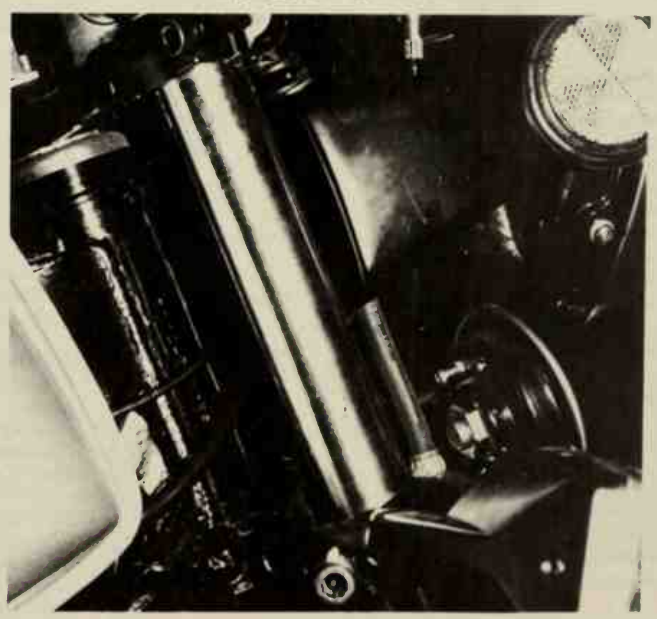
SERIAL NUMBER LOCATION

In order to prevent possible confusion when purchasing parts, always refer to the engine and frame serial numbers. The frame number is stamped on the right side of the steering lug, while the engine number is behind the cylinders on the top right side of the crankcase.

Engine serial number location

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in the "General Information" section.*

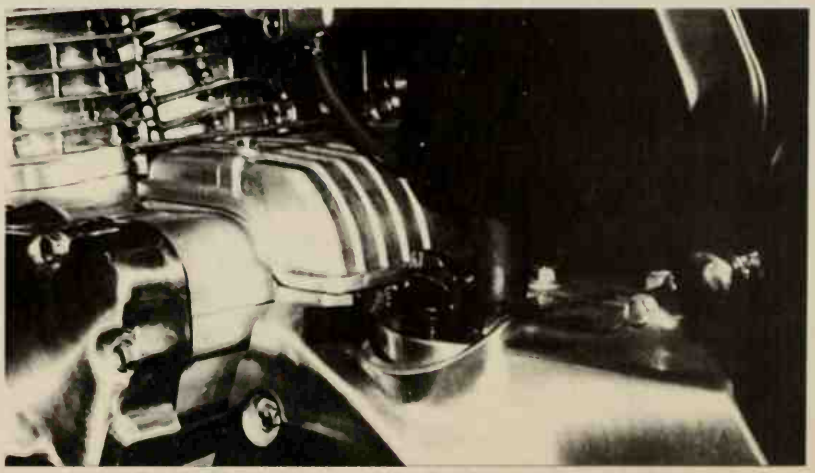


LUBRICATION

Motor Oil

For use in all temperatures, Honda recommends SAE 10W-40 motor oil, service rating "SE" or "SF."

1969–78



1. Due to the dry-sump lubrication system, if the machine has been sitting idle for more than a few hours the engine must be run for several minutes before the oil is checked.
2. The motorcycle should be parked on the center stand on level ground.
3. Check the oil level with the dipstick that is part of the oil tank cap. The level should be between the upper and lower marks inscribed on the dipstick. If the oil level is below the lower level mark, top it up with the proper grade of oil to bring the level to the upper mark.

Frame serial number location

Upper and lower oil level marks

The dipstick must rest on top of the threads for an accurate reading

750A

1. The 750A has a wet-sump lubrication system, all of the oil being contained in the crankcases.

2. Allow the engine to run for several minutes before checking the oil level.

3. With the machine parked on the center stand on level ground, and with the engine shut off, unscrew and remove the dipstick and wipe it clean. Reinsert the dipstick, allowing it to rest on the threads of its hole. Do not screw it in. Remove it and check the level. It should be between the upper and lower level marks inscribed on the dipstick. If it is at or near the lower mark, add enough oil to bring the level up to the upper mark, but do not overfill the crankcase.

1979–81

1. These models have a wet-sump lubrication system, all of the oil being contained in the crankcases.

2. Allow the engine to run for several minutes before checking the oil level.

3. With the machine parked on the center stand on level ground, and with the engine shut off, unscrew and remove the dipstick and wipe it clean. Reinsert the dipstick, allowing it to rest on the threads of its hole. Do not screw it in. Remove it and check the level. It should be between the upper and lower marks inscribed on the dipstick. If it is at or near the lower mark, add enough oil to bring the level up to the upper mark, but do not overfill the crankcase.

Wet-sump dipstick level marks

Changing Oil

NOTE: *Manual transmission models 1969–1978 have a dry-sump lubrication system.*
1979–1981 models have a wet-sump system, as does the 750A.

1. The recommended oil change interval is 1,500 miles or 3 months for manual transmission models 1969–1978, 3,000 miles or 6 months for the 750A, and 4,000 miles or 1 year for 1979–1981 models.

Time and mileage intervals are both important and the oil should be changed at whichever occurs first.

These intervals are based on normal motorcycle usage *after* initial break-in is completed.

2. Oil should be changed when the engine is warm. This ensures more complete draining and makes it more likely that the oil will carry off any particulate matter with it.

3. On dry-sump models, remove the oil tank cover, raise the seat (if necessary), and remove the tank filler cap. Remove the tank drain plug, draining the oil into a suitable container (at least 4-qt capacity). After drain-

ing is completed, check the condition of the drain plug gasket, replacing it if necessary; then install the plug and tighten it securely (torque to about 25 ft. lbs.). Remove the crankcase drain plug, allowing this oil supply to drain for several minutes. Kick the engine over several times with the kickstarter to remove any oil in the delivery system. Install the plug and tighten it to about 25 ft. lbs.

Oil tank drain plug

750A crankcase drain plug

4. On 750A and 1979–1981 models, all of the oil is contained in the crankcases, and it can all be removed after the drain plug is taken out. Your container should be able to hold more than 4 qts. Check the condition of the drain plug gasket, and install the plug, tightening to 25–33 ft. lbs. on the 750A and 25–29 ft. lbs. on 1979–1981 machines.

5. If the oil filter is to be replaced, see "Oil Filter," below.

6. On the 750A, add about 4.2 qts (4.0 l) of SAE 10W-40 oil to the engine. Secure the filler cap and allow the engine to run for several minutes. After shutting it off, check the oil level and top up if necessary.

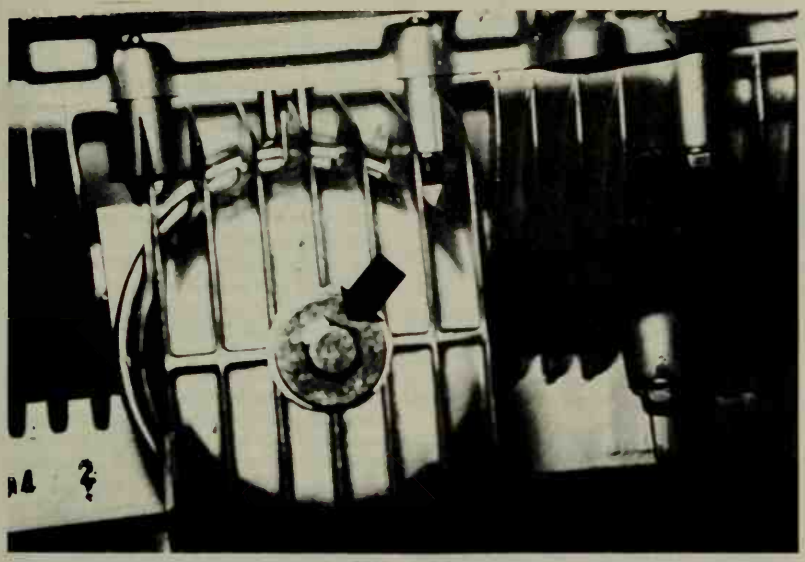
7. On all other 1969–1978 models, add about 2.6 qts (2.5 l) of SAE 10W-40 motor oil to the tank. Start the engine and allow it to run for several minutes. Then shut it off and check the oil level. It will be necessary to add additional oil until the level is at the top dipstick mark. System capacity is 3.7 qts. (3.5 l).

8. On 1979–1981 motorcycles, add about 3.7 qts. (3.5 l) of SAE 10W-40 motor oil, or equivalent. Tighten the dipstick, start the engine and let it run for a minute or so. After shutting it off, check the oil level and top up if necessary.

Oil Filter

1. The filter element should be changed at every oil change on the 1979–1981 models and the 750A, at every other oil change on 1969–1978 models.

2. After removing the crankcase drain plug and allowing the oil to run off, remove the oil filter housing bolt, placing a drip pan or suitable substitute beneath the housing to catch any oil in the filter housing.



3. Take out the old filter, washer, and spring. Clean the housing. Check the condition of the housing o-ring.

4. Wipe off the mating surface on the crankcase with a clean rag. Oil the o-ring lightly with clean oil.

5. Slipping the filter housing bolt into place, fit the spring and washer, then the

Removing the filter from the housing

Oil filter bolt

new filter element. Install the housing, tightening the housing bolt to 20–24 ft. lbs.

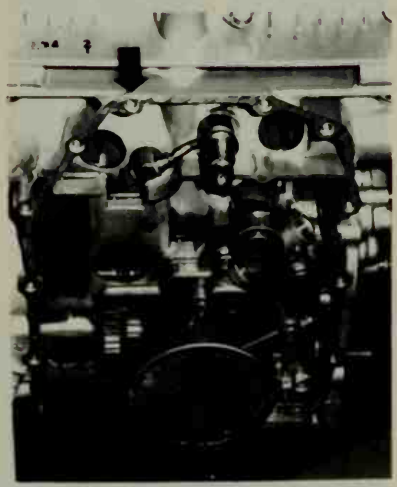
CAUTION: *Do not overtighten the housing bolt. If this is done, it will not only be difficult to remove, but it may crack the housing in the area around the bolt hole. If the bolt is difficult to remove, be sure to inspect the housing closely around the bolt hole for small cracks.*

6. Add oil to the crankcase or oil tank as outlined under "Changing Oil" above.

Filter Screen

1. All models are equipped with a filter screen in the sump which should be cleaned and inspected at 12,000-mile or 24-month intervals.

2. After draining the sump, unbolt and remove the oil pan.



On 1979–1981 models, note the locations of the three pan bolt copper washers which are located on the right side.

3. Withdraw the screen from the oil pump, and clean it in a safe solvent, brushing off foreign matter if necesary. Inspect the screen mesh for holes, and replace it if any are noted.

4. When installing the pan, a new gasket should be used. After refilling the system with oil, start the engine and check for leaks around the oil pan mating surface.

Note that after pan rmoval, the engine may require more oil than after a routine change.

Oil pan bolts should be torqued to 7–10 ft. lbs.

Arrows indicate holes for bolts which have copper washers

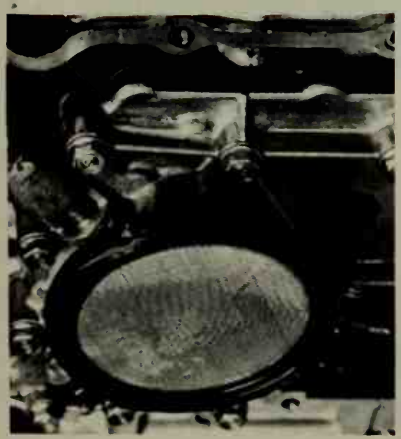
Oil Path Body (1979–80)

The oil path body should be checked when the filter screen is serviced. Remove the oil path body after the screen. Check it for cracks or other damage. Replace it if any is noted.

Note: All replacement oil path bodies have an oil flow restriction and can be installed even if the original part does not.

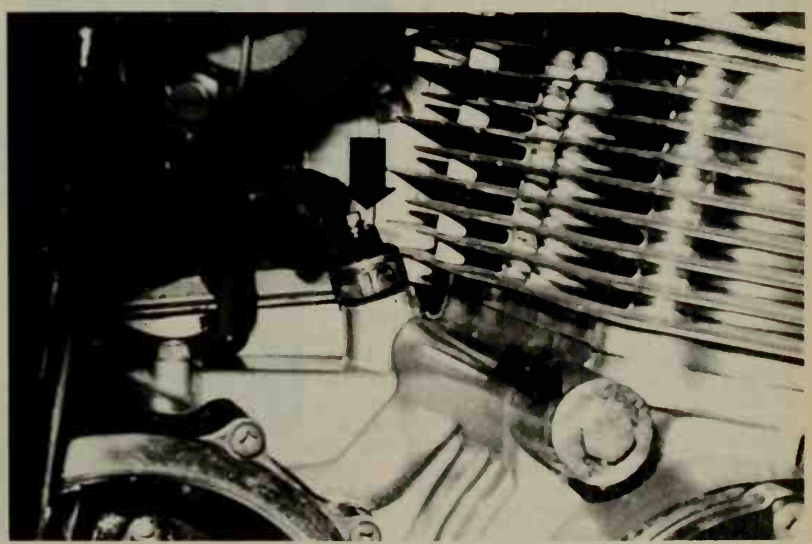
Oil Pressure (1969–78)

Oil pressure should be checked every 6,000 miles or 12 months. A gauge may be connected at the oil gallery access hole at the right side of the engine after the plug has been removed. Honda service tools No. 07068-30001 (adapter) and No. 07065-30001 (pressure gauge) may be used. The gauge should register 50–64 psi when the engine is warm (oil temperature 140–160°F) and running at 3,000 rpm. If the oil is cold, a higher reading will be obtained.



If oil pressure is unsatisfactory, determine and correct the fault. Refer to chapter 5, "Lubrication Systems," for additional information.

Oil Pressure (1979–80)



Oil pressure should be checked every 6,000 miles or 12 months. Honda service tools No. 07506-3000000 (oil pressure gauge) and No. 07510-4220100 (adapter) may be used. The gauge is attached to the oil pressure switch hole behind the cylinders.

Check the pressure when the engine is at operating temperature (about 176°F/80°C). At 7,000 rpm, pressure should be 71 psi. If the oil is cold, a higher reading will be obtained.

If oil pressure is unsatisfactory, determine

Crankcase filter screen

Oil pressure sensor and gallery plug (1969–1978)

Oil pressure sensor and pressure gauge fitting (1979–1981)

the reason and correct the fault before further operation of the motorcycle. Refer to "Lubrication Systems," for additional information.

Use a liquid sealant on the threads of the oil pressure switch when reinstalling it. Check that the oil pressure light operates properly.

Transmission Oil Pressure (750A)

A test of the transmission oil pressure is undertaken in the event of trouble. Refer to "Engine and Transmission."

Subtransmission Oil

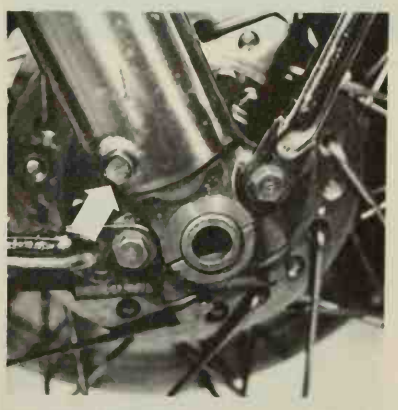
A level plug is fitted to enable a quick check of the subtransmission oil level.

1. Park the motorcycle on the center stand on a level surface.
2. Shift the subtransmission into "Low."
3. Remove the cover.
4. Remove the level plug. The oil should be level with the lower threads of the plug hole. In other words, oil should just begin to ooze out.

Add SAE 80 hypoid gear oil if the level is low.

5. To change the oil, proceed as above. Remove the drain bolt and the filler cap.
6. Fit the drain bolt after several minutes have elapsed.

NOTE: *Draining will be much quicker if the engine is at operating temperature.*



7. Tighten the drain bolt to 12–14 ft. lbs.
8. Add about 20.4 oz. (600 cc) of SAE 80 hypoid gear oil to the subtransmission. Check the level as before.

Rear Drive Box

1. To check the oil level in the rear drive box, park the machine on the center stand on a level surface.
2. Remove the level plug/filler. The oil should be just level with the bottom threads of the hole, or just ready to ooze out. Add SAE 90 hypoid gear oil for temperatures above 40°F or SAE 80 for temperatures below this.
3. To change the oil, remove the drain bolt and allow the oil to drain for several minutes. Draining will be quicker if the engine is at operating temperature.
4. After refitting the drain bolt, add 5.1 oz. (150 cc) of the proper oil grade. Check level as before.

Front Forks (1969–80)

1. ATF oil is recommended for all forks after 1972, SAE 10W-30 oil for forks 1972 and earlier. If slightly stiffer damping characteristics are desired, SAE 20 or SAE 30 oil can also be used. Special types of oil designed specifically for motorcycle forks can also be used, although care must be taken to flush the forks thoroughly when changing types or brands of fork fluid, since some may be incompatible with others.
2. Fork oil should be changed every 6,000 miles or 12 months on all 1969–1978 models except the 750A, whose recommended interval is 12,000 miles or 24 months. Models 1979–1980 should have this service done at 4,000 miles or 12 month intervals.

Front fork oil drain plug

Fork filler cap

3. Place a container beneath one of the fork sliders and remove the drain plug. Pump the slider up and down until all the oil is expelled. Examine the plug gasket, then refit the plug. Repeat the procedure with the other slider.
4. Examine the drained oil. If it contains water or is exceptionally dirty, it may be that the fork gaitors or dust covers are damaged and allowing foreign matter to get past. This will also damage fork seals quickly. Check that the gaitors or dust covers are properly secured and replace them if cracked, ripped, or otherwise damaged.
5. Support the front wheel off the ground by placing a scissors jack or similar device beneath the engine.
6. Remove the handlebar clamp bolts and move the bars to one side or the other to allow access to the fork filler caps.
7. Remove the rubber cap plugs on 1979–1980 machines. Remove the fork filler caps. Often loosening the upper triple clamp pinch bolts will make it easier to remove the caps. Since the caps are under spring tension, care should be exercised when removing them. Note the spring seats below the caps on some models.
8. Remove the fork springs to facilitate the job of adding the fork oil. Add the proper amount to each leg, as given in the "Maintenance Data" chart at the end of this section
9. Inspect the filler cap o-rings for damage and replace them if necessary. Fit the springs, seats (if fitted), and caps, tightening them securely.

Proper filler cap torque is 40–47 ft. lbs. (1969–1978) or 15–22 ft. lbs. (1979–1980). Tighten the triple clamp pinch bolts if they were loosened. Secure the handlebars, tightening the forwardmost bolts first.

10. After several miles of operation, check the area around the fork slider seals for leaks or seepage. Even a minimal amount of seepage will require replacement of the seals. A coating of grime building up in this area over a period of time is also indicative of ineffective seals.

Air Forks (1981)

No routine oil changes are necessary on these forks. Refer to "Chassis" for service procedures.

Drive Chain

1977–81 MODELS

These models are fitted with a chain which has rubber o-rings between the plates to aid lubricant retention.

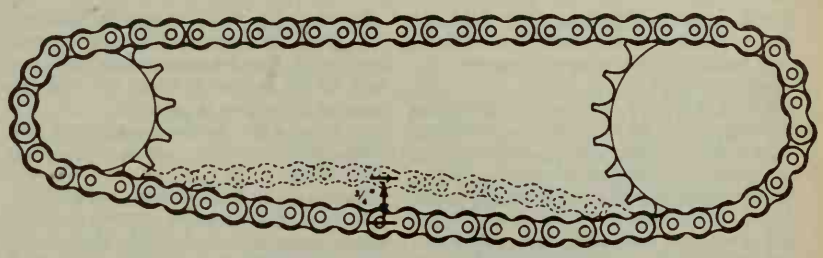
The chain should be lubricated about every 300 miles, or sooner if it appears to be dry. For lubrication, use SAE 80 or 90 weight gear oil only. Do not use commercial chain lubricants, as they may contain additives which will damage the rubber o-rings.

About every 2,000 miles, the chain should be cleaned with kerosine.

The chain o-rings can be damaged by steam cleaning, high-pressure spray, and certain solvents. Keep this in mind when cleaning the motorcycle.

1976 AND EARLIER MODELS

Chains for these models are serviced in the usual manner. Refer to the "General Information" section under "Maintenance."



On models with a chain oiler incorporated into the engine sprocket shaft, adjust the oiler as follows:

1. Remove the engine sprocket cover and wipe the sprocket and chain clean.
2. Ride the bike for a minute or two at about 50–60 mph, then stop and check the oil output to the chain. Normal output will yield a chain which is wet with oil, but the lubricant should not be found on the tire or rim.

3. To increase chain oil flow, turn the adjusting screw counterclockwise about ¼ turn, and recheck. To decrease the oil feed, turn the screw clockwise about ¼ turn and recheck.

4. Maximum output is obtained when the adjusting screw is turned out about three turns from the seated position.

It is recommended that the chain be lubricated periodically with a good brand of motorcycle chain lubricant in any case, since motor oil is not the best chain lubricant.

Chain play should be measured in the middle of the lower run

Chassis Lubrication

1. The swing arm pivot is fitted with one or two grease nipples which should be lubricated with chassis grease every 3,000 miles. On most models the nipples are on the ends of the swing arm pivot shaft, while the latest designs have a single nipple in the middle of the swing arm.

Swing arm grease fitting (early)

2. Wheel and steering head bearings are lubricated with bearing grease, the service interval being 12,000 miles or 24 months. Refer to "Chassis," for procedures.

Drive Shaft Coupling

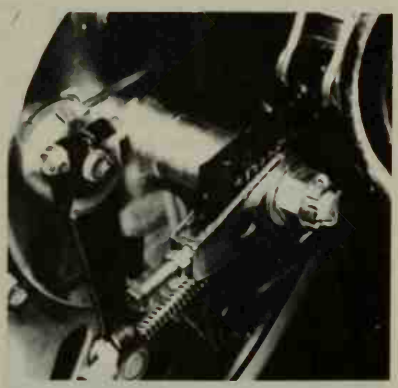
Shaft-drive models have a grease fitting located on the rear drive box.

Use lithium-based chassis grease to lubricate the coupling every 8,000 miles.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about 20mm (¾ in.) of total up-and-down free-play measured in the middle of the lower chain run.



2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on the center stand so that the rear wheel is off the ground;

b. The transmission should be placed in neutral;

c. The chain should be clean and well-lubricated;

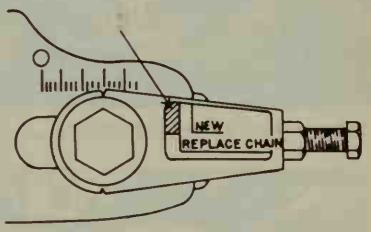
d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably worn sprockets, which should be replaced as soon as possible.

Chain adjuster bolt (arrow)

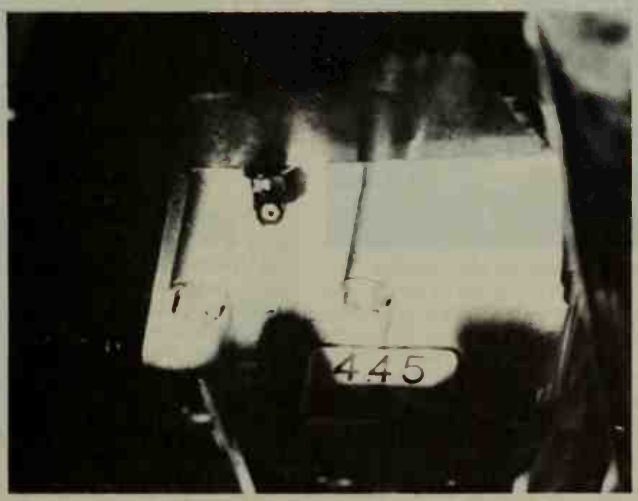
3. To adjust the chain, first back off the rear brake adjuster nut on drum rear brakes.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

5. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately correct.



6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.



7. Tighten the axle nut and adjuster bolt nuts and check the chain tension. The chain tension should also be checked with the weight of a rider sitting on the motorcycle when it is off the center stand; the chin should still have at least ½ in. of free-play. Correct if necessary. After adjustment is correct, torque the axle nut to 60–72 ft. lbs.

Fit a new cotter pin. Readjust the rear brake on drum brake models.

will wear out a set of sprockets in short order.

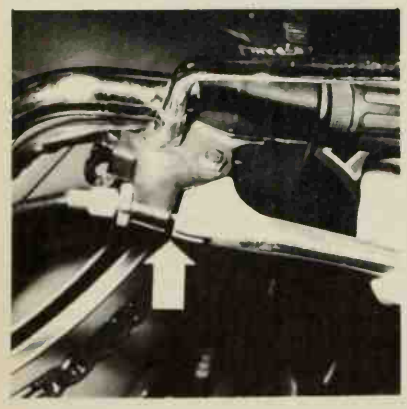
8. 1977 and later models have a plate on the chain adjuster which indicates the replacement limit for the chain. This should be done when the edge of the red zone aligns with the rear of the swing arm.

Swing arm grease fitting (late)

Clutch

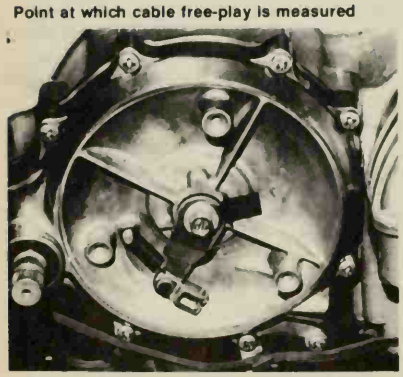
750

1. Cable adjustment must always be maintained at the proper specification. If the cable has insufficient free-play, the clutch will slip and rapidly burn out. If it has too much play, the clutch will not completely disengage, resulting in hard shifting and creeping at stops.



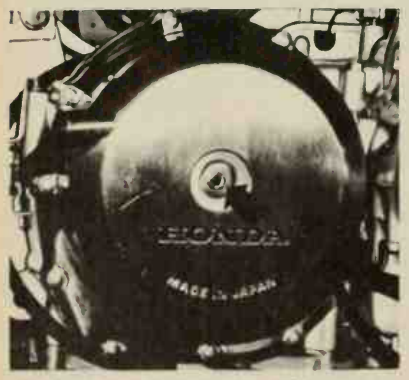
2. Use the cable adjuster at the handlebar or engine to maintain the correct amount of cable slack. The clutch hand lever should be

able to be moved 2–3mm (0.08–0.12 in.) measured between the clutch lever and the lever holder before the clutch begins to disengage.



It should not be necessary to screw the cable adjuster at the handlebar out very far to make and to maintain this adjustment. If it is necessary to screw the handlebar adjuster out so that more than about 8 mm (0.3 in.) of thread are showing, screw it in several turns, and proceed to make the cable adjustment with the adjuster at the lower end of the cable. Use the handlebar adjuster for fine adjustment.

If clutch operation is not satisfactory after properly adjusting the cable, the problem may be in the clutch itself.



First make sure that the cable is properly lubricated and free to move in the sheath. Lack of lubrication, dirt, or rust in the cable can cause it to bind or otherwise impair operation.

Point at which cable free-play is measured

Clutch adjustment screw (1969–1978)

Clutch adjustment screw (1979–1980)

To adjust the clutch, proceed as follows:

3. Screw the cable adjuster at the lever all the way in, thus increasing cable free-play. Back off the locknut and turn the cable adjuster at the engine in as well.

4. Remove the clutch housing cover plate (1969–1978) or the clutch lifter cap (1979–1981).

Loosen the clutch adjusting screw locknut.

5. Turn the adjusting screw clockwise until a slight resistance is felt, then turn it counterclockwise ¼ turn (1969–1978) or ¾ turn (1979–1981). Holding the screw in this position, tighten the locknut.

6. Turn the cable adjuster at the engine out until there is about 13 mm (0.5 in.) of free-play in the hand lever. Tighten the locknut on the engine cable adjuster.

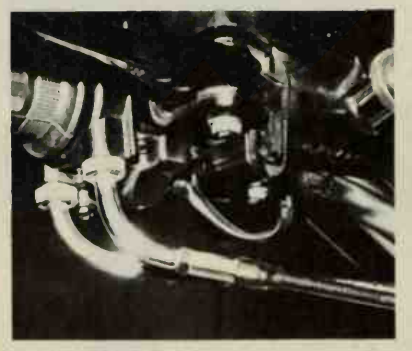
7. Make any further minor adjustments with the adjuster at the hand lever.

900

1. Adjust the clutch cable in the same way as described for 750 models outlined above.

2. Adjust the clutch in the manner described for the 750 (Step 5, above), but back the adjusting screw off 1½ turns for the 900.

Throttle Cable



1969–1978

1. The throttle cable is fitted with an adjuster at the twist-grip. The twist-grip should be able to be rotated approximately 10–15° (2–4 mm [0.08–0.16 in.]) before the throttle slides begin to open.

2. Use the cable adjuster at the handlebar to make and maintain this adjustment. To check that the cable has sufficient slack, start the engine and turn the forks slowly from lock-to-lock. Idle speed must not increase. If it does, it indicates that the cable has insufficient free-play, is incorrectly routed, or is binding at some point.

3. For complete throttle cable and linkage adjustments, refer to chapter 3, "Tune-Up."

4. For major cable adjustments, use the adjuster(s) at the carburetors.

Throttle cable adjuster

1979–1981

1. The throttle cable is fitted with an adjuster at the twist-grip. The twist-grip should be able to be rotated approximately 2–6 mm (0.08–0.24 in.) before the butterflies in the carburetors begin to open.

2. Use the cable adjuster at the handlebar to make and to maintain this adjustment. To check that the cable has sufficient slack, start the engine and turn the forks slowly from lock-to-lock. Idle speed must not increase. If it does, this indicates that the cable has insufficient free-play, is incorrectly routed, or is binding at some point, perhaps due to a kink or dirt or corrosion inside the sheath.

NOTE: *The accelerator pump may flood the engine if the twist-grip is operated several times in succession.*

3. For complete throttle cable and linkage adjustments, refer to "Tune-Up."

4. For major cable adjustments, use the adjuster(s) at the carburetors.

Brakes

FRONT DISC

Disc brakes need no attention other than a periodic check of fluid level and pad wear:

1. On late models with a see-through reservoir, fluid level can be checked at a glance. Turn the handlebars so that the fluid level is parallel to the ground for an accurate check.

If the level is near the lower mark, add enough DOT 3 brake fluid to bring it up to normal.

Maintain breke fluid level at the inscribed line

NOTE: *Brake fluid is hydroscopic. It absorbs moisture. Therefore, do not use fluid from an old or unsealed container. Exercise extreme care in handling the brake fluid.*

CAUTION: *Clean the reservoir thoroughly with a rag before removing the cap. Turn the handlebars fully to the right before the cap is removed to avoid spillage. Cover the tank with a cloth. Brake fluid removes paint.*

2. On earlier models, the reservoir cap and diaphragm beneath it must be removed to check the fluid level. Clean around the reservoir with a rag to remove any dirt before removing the cap.

If the level is below the line inscribed on the inside of the reservoir, add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and cap and tighten it securely.

If the cap is overtightened, the reservoir may weep fluid.

NOTE: *Read the "Note" and "Caution" in Step 1, above.*

CAUTION: *Fluid level may drop slightly as the pads wear. But if the drop is significant, it may indicate a system leak. Check the system thoroughly in any case noting any dirt or sludge build-up at hose junctions, near rubber boots, around the caliper piston(s), etc.*

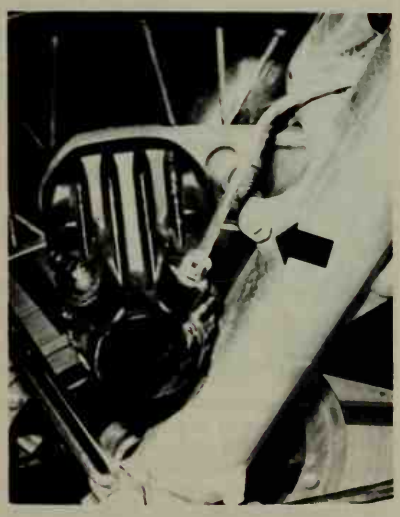
3. Check the brake pad wear, and replace the pads in a set if either one is worn to the red limit line (1972 and later). On pre-1972 brakes, check the clearance between the front of the caliper and the disc. Replace both

Fluid level lines are inscribed on the master cylinder reservoir

pads if clearance is less than 1.5 mm (0.06 in.).

Refer to "Chassis," for brake system service procedures.

4. If the brake lever feels spongy, bleed the system. This procedure can also be found in "Chassis."



5. Early models are equipped with an adjusting screw on the handlebar lever bracket. After loosening the adjuster locknut, turn the adjuster to allow ¼ to ½ in. of lever travel (measured at the tip of the lever) before the pads are fully forced against the disc. This adjustment usually will not need to be reset once lever travel is correct. If the lever travel becomes excessive and the brake pads are satisfactory, suspect air in the brake lines.

Warning: Do not operate the brake lever with reservoir cap or caliper pads removed.

Caliper Adjustment

Early model swinging-type brake calipers (see illustration) should be adjusted whenever new pads are fitted, or if the brake seems to drag or causes a squeaking as the wheel turns.

1. Raise the front wheel off the ground.
2. Loosen the adjusting screw locknut and turn the adjusting screw *counterclockwise* until the innermost pad contacts the disc. A slight drag will be noted when spinning the wheel.
3. Turn the adjusting screw *clockwise* until the wheel spins freely; then turn the adjusting screw ½ turn more in the same direction and tighten the locknut.
4. Check that the wheel turns freely without drag. Check for proper brake operation.
5. Brakes which drag constantly after application and which cannot be cured with proper caliper adjustment may be caused by sticking or seizure of the caliper bracket on its pivot. Free movement of the caliper is necessary for proper operation of the brake. This can be inhibited by dirt or other foreign matter between the pivot and caliper bracket. If the wheel will not turn freely after the brake is applied, try striking the caliper with the heel of your hand. If this frees the wheel, it is probable that the swinging bracket is becoming stuck. A penetrating fluid or parts lubricant applied to the bracket pivot will often remedy this problem.

Caliper adjusting screw

REAR DISC

NOTE: *Read the "Notes" and "Cautions" under "Front Disc," above, regarding the use and handling of brake fluid.*

1. The transparent master cylinder allows inspection of the fluid level without removing the reservoir cap. If the fluid level is below the level mark, remove the cap and diaphragm and add enough DOT 3 brake fluid to bring the level up to the proper level. Clean the reservoir off with a rag before removing the cap to keep out dirt. Reinstall the diaphragm and cap and tighten it securely.

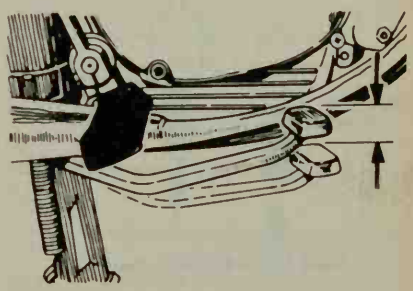
If the cap is overtightened, the reservoir may seep fluid.

Rear master cylinder level lines

CAUTION: *Do not operate the brake pedal with the cap removed.*

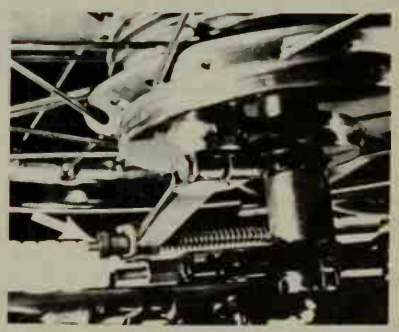
2. A brake wear indicator is fitted to the rear caliper, so that pad wear can be checked easily after removing the cover. If either pad is worn to the red mark on the caliper, replace the pads as a set.

3. On 1978 and earlier models, pedal height can be adjusted to suit personal preference by loosening the brake rod locknut, removing the cotter pin and clevis pin from the rod, and then turning the clevis. Lengthening the rod will raise the pedal, and vice-versa. Maintain adequate clearance between the brake pedal arm and the bottom of the footpeg.



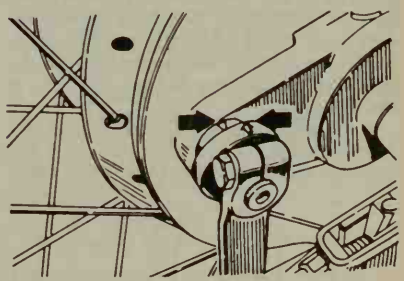
4. On 1979 and 1980 models, pedal height should be adjusted so that the top of the pedal is about 7 mm (0.25 in.) above the top of the footpeg rubber. This adjustment can be made by turning the adjuster locknut until it is loose, then turning the adjuster until proper pedal height is obtained. Tighten the locknut.

5. If brake pedal height is changed, check the operation of the brake light switch.



REAR DRUM

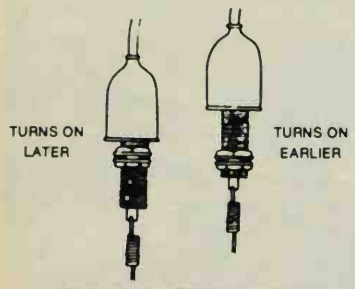
1. Brake lining wear on newer models can be determined by means of the wear indicator pointer fitted to the brake lever on the hub. If the pointer lines up with the red slash mark when the brake pedal is fully applied, the linings are worn as far as possible for effective braking and should now be replaced.



2. On older models, observe the angle formed by the brake lever on the hub and the brake rod when the brake is fully applied. When the lever and rod from an angle greater than 90°, the shoes should be checked for wear as they probably are worn to the point of needing replacement.

The brake pedal should have about 1 inch of movement before the linings contact the drum

Rear brake adjusting nut



Brake wear indicator marks

3. The rear brake should be adjusted so that there is approximately 25 mm (1.0 in.) free-play at the pedal before the linings contact the drum. Adjust by turning the hex nut on the brake rod. When adjustment has been made, be sure that the nut is seated properly on the brake lever pin. Also, check the operation of the brake light switch.

4. Brake pedal position may be adjusted to suit individual taste by backing off the brake adjusting nut, loosening the pedal height adjusting bolt locknut, and turning the bolt until pedal position is satisfactory. Thereafter, adjust pedal free-play and the brake light swich.

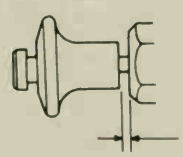
Brake Light Switches

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch and adjuster nut are mounted on a slotted bracket. The rear switch is adjusted by holding the switch and turning the adjuster.

Brake light switch connections

Moving the switch upon the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to effect adjustment as the wires will become twisted and may break. Generally, the brake light should come on just as the linings contact the drum or just as the brake begins to operate in the case of disc rear brakes.

The front switch is activated by the pressure of the brake fluid in the brake line. This switch is not adjustable; if defective, it must be replaced.



Parking Brake (750A)

1. The parking brake cable should have 2 mm (0.08 in.) of free-play.

2. To adjust the cable, remove the brake pedal pinch bolt and carefully pull the pedal from its shaft. Slide the ratchet mechanism dust cover up the cables and out of the way. Adjust the cable to the proper free-play by loosening the adjuster locknut and turning the adjuster.

3. Check operation. If the parking brake knob is pulled out and returns by itself, the cable is much too tight. Once the knob is pulled, the brake pedal should lock after being depressed about 20 mm (0.8 in.). If it will not lock, check the condition of the ratchet pawls (refer to chapter 8, "Chassis").

4. Be sure that the ratchet mechanism bears against the parking brake light switch. The switch should be fully screwed into the mechanism housing.

The parking brake cable should have about 2 mm (0.08 in.) of free-play

Neutral Return Rod (750A)

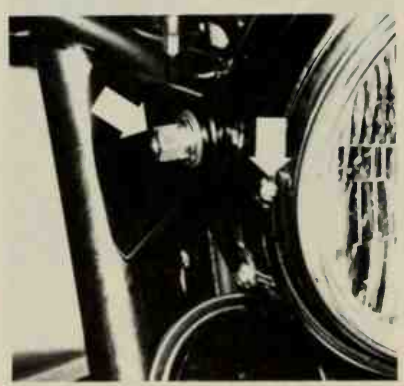
1. The shift lever must return to the "N" (neutral) position each time the side stand is lowered. Routine adjustment should not be necessary, but if the shift lever will not return to "N," proceed as follows:

2. Park the bike on the center stand. Retract the side stand and shift the transmission into the "D" (drive) position.

3. Loosen the return rod locknut, and turn the rod in a clockwise direction when viewed from the rear of the machine. When it stops, rotate it one turn in the opposite direction and tighten the locknut.

4. Check operation by setting the side stand down. The stand should bear against its stop, and the transmission must shift into "N."

5. If adjustment will not yield proper operation, check the return rod spring for a weak or partially collapsed condition and replace it if necessary.



Headlight Adjustment

1. Set the machine about 25 feet away from the perpendicular to a wall, preferably of a color which reflects light well.

The machine should be off the stand, and with a rider putting his weight on the machine as in operation.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

3. Vertical adjustment is made by loosening the two headlight shell mounting bolts slightly and pivoting the shell up or down.

Vertical and lateral headlight adjustment points

4. Lateral adjustment is accomplished by means of the screw on the right side of the headlight. On 1969–1978 models, turning the screw clockwise will move the beam to the left, turning it counterclockwise will move it to the right.

On 1979–1981 models, turning the screw clockwise will move the beam to the right, and vice-versa.

FUEL SYSTEM

Fuel system maintenance involves cleaning the petcock and fuel filter screen, cleaning or replacing the air cleaner, cleaning the carburetors, and cleaning the breather element or tube (if so equipped).

On 1969–1978 models, the normal service interval is 3,000 miles. Every 6,000 miles, the air cleaner element should be replaced.

On 1979–1981 models, the normal service interval is 4,000 miles. The air cleaner element should be replaced every 8,000 miles.

Petcock

1. Two types of petcock are fitted, the change occuring on 1975 models.

2. On 1974 and earlier models, shut off the fuel and unscrew and remove the sediment bowl. Take out the o-ring and the fuel filter screen. Clean the bowl and filter screen in solvent and inspect the filter for any holes or other defects. If punctured, or so badly clogged that it cannot be properly cleaned, replace the screen. Inspect the o-ring for cuts or cracks. Reinstall the screen, o-ring, and sediment bowl. Turn on the petcock and check for leaks before operation.

Petcock filter screen and o-ring

3. In 1975 and later models, the petcock filter screen is inside the gas tank. Shut off the fuel flow and disconnect the fuel lines. Remove the gas tank and drain off the gas. Unscrew its securing nut and carefully take out the petcock. Remove the filter and securing nut from the petcock. Wash the filter in solvent to remove any foreign matter. Replace the filter if it is badly clogged or if punctured. Check the condition of the gasket and replace it if it is crushed or nicked. Installation is the reversal of removal. Be sure that the fuel lines are properly secured to the petcock with safety clips. Check for leaks before operation.

Air Filter

1969–78

1. Remove one of the side covers. Access to the filter element is gained by removing either the wing-nuts on the underside of the air cleaner case or the mounting bolts on top of the case, depending on the model.

2. Remove the lower half of the case and take out the filter element.

3. Tap the element lightly to remove any loose dirt, or use a reasonably soft brush to remove deposits. Blow out remaining dirt by

Air cleaner box wing nuts (1969–1978)

applying compressed air to the inside of the element, if feasible.

4. Since cleaning paper elements is only partially effective, the unit should be replaced with a new one every 6,000 miles, or more often if used in a dusty environment.

1979–81

1. Remove the left side cover.
2. Remove the two air cleaner cover screws and take off the cover.
3. Pull out the air cleaner element set spring and remove the element.
4. Tap the element lightly to remove any loose dirt, or use a reasonably soft brush to remove deposits. Blow out remaining dirt by applying compressed air to the inside of the element, if feasible.
5. Since cleaning paper elements is only partially effective, the unit should be replaced with a new one every 8,000 miles, or more often if used in a dusty environment. If in doubt, and the element seems excessively dirty, replacement is recommended.
6. Installation is the reverse of removal.

Air cleaner box screws (1979–1980)

Breather Element

1. A crankcase rebreather is fitted to late models before 1979. The breather is accessible after raising the seat.
2. Remove the breather case mounting bolt and disconnect the lines.
3. Remove the two case screws and separate the components: case cover, cover gasket, spring, retaining plate, and breather element.
4. Wash the element in a safe solvent and dry thoroughly. Refit the components in the reverse of the removal procedure.

Breather Tube

1. Models 1979–1981 are fitted with a plugged breather tube which must be drained at the fuel system service interval.
2. Remove the drain plug and allow the deposits to drain into a small container. When refitting the plug, be sure that it is pushed all the way into the tube.

Breather tube location

Recommended Lubricants

Engine
- General, all temperatures: SAE 10W-40, service rating "SE" or "SF"
- Above 60°F (15°C): SAE 30
- 15° to 60°F (–10° to 15°C): SAE 20 or 20W
- Above 15°F (–10°C): SAE 20W-50, service rating "SE" or "SF"
- Below 32°F (0°C): SAE 10W

Subtransmission
- SAE 80 Hypoid gear oil

Front forks
- ATF (1973 and later)
- SAE 10W-30 (1972 and earlier)
- SAE 20W
- SAE 30W

Rear drive box
- Above 40°F: SAE 90
- Below 40°F: SAE 80

Disc brakes
- DOT 3 standard brake fluid

Control cables
- Light motor oil
- Graphite-based lubricant
- Molybdenum-disulphide-based lubricant

Tach. speedometer cables; throttle twist-grip
- Light duty grease

Wheel and steering head bearings
- Waterproof, medium-weight bearing grease

Grease fittings
- Waterproof, medium-weight chassis grease

Drive chain
- 1969–1976: Lubricant developed specifically for motorcycle drive chains
- 1977–1981: SAE 80 or 90 gear oil

Periodic Maintenance Intervals ①

Before each ride
- Safety items
- Operation of lights
- Chain adjustment
- Control cable adjustment

Weekly
- Engine oil level
- Tire pressure (check when cold)
- Battery electrolyte level

Every 200 miles
- Lubricate chain (1976 and earlier)

Every 500 miles
- Check tightness of critical fasteners
- Lubricate chain (1977 models)

Every 1,500 miles/3 months
- Change engine oil (1969–1978 except 750A)

Every 2,000 miles
- Clean and lubricate drive chain

Every 3,000 miles/6 months
- Change engine oil (750A)
- Change oil filter (1969–1978)
- Service all grease fittings
- Clean breather element (if fitted)
- Clean air filter element (1969–1978)
- Lubricate breaker cam felt
- Clean fuel petcock screen
- Lubricate all controls and cables
- Check disc brake fluid level
- Check brake pads or shoes for wear
- Check operation of brake controls
- Check clutch operation
- Check condition of chain and sprockets
- Check condition of fuel lines
- Clean and check carburetor operation
- Check spokes for tightness
- Check swing arm bushings
- Clean and gap or replace spark plugs
- Clean and gap breaker points
- Check ignition timing
- Adjust valve clearance
- Adjust cam chain tensioner

Every 4,000 miles/12 months
- Change engine oil (1979–1981)
- Change oil filter (1979–1981)
- Change fork oil (1979–1981)
- Clean air filter element (1979–1981)

Every 6,000 miles/12 months
- Check parking brake (750A)
- Change fork oil (1969–1978 except 750A)
- Replace air filter element (1969–1978)
- Adjust steering head bearings
- Check oil pressure

Every 8,000 miles
- Replace air filter element (1979–1981)
- Lubricate drive shaft coupling (900)

Every 12,000 miles/24 months
- Flush and refill disc brake system
- Clean oil filter screen
- Change fork oil (750A)
- Repack wheel and steering head bearings

Every 24,000 miles/48 months
- Change subtransmission oil (900)
- Change drive box oil (900)

①Based on normal usage after initial service and break-in are completed.

NOTE: *The breather tube should be drained more frequently if the motorcycle is used in the rain or often at wide open throttle.*

Carburetors

1. Although major overhaul of the carburetors requires their removal as a unit, the float bowl and jets can be cleaned with the units in place.

2. Make sure the petcock is shut off. Drain the fuel from the carburetor float bowls.

3. On most models, the foat bowls are secured with a retaining clip. When flipped up, carefully lower the float bowl until it is clear of the floats. On late models, the float bowls are secured by phillips screws. Observe the same cautions when removing them.

4. Unscrew the pilot jet. With a suitable socket, unscrew and remove the main jet holder, which will come out with the main jet and emulsion tube. On 1979–1981 models, the primary main jet comes out with a screwdriver. Blow the jets clear, then install. Clean any residue out of the float bowl. When installing, be sure to position the bowl carefully to avoid damage to the floats. If secured by screws, tighten them gradually and evenly.

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in the "General Information" section.*

Twin-cam models (1979–80) require feeler gauges, a micrometer, and a special tool to hold down the valve spring for valve clearance adjustments.

For ignition timing on 1969–78 models, marks are provided to determine piston position, but a test light or ohmmeter is necessary to determine when the points open. If the dynamic timing method is used, an automotive-type strobe light is needed. The strobe light can be used to check the timing both at idle and at full advance, and therefore this method is considered the most accurate way of setting the timing.

1979–81 models feature a transistorized breakless ignition system. Timing should be checked with a strobe light. There is a static timing check possible, bu the results will not be as accurate.

CAUTION: *Due to the automatic transmission, all running engine adjustments to the 750A must be carried out with the rear wheel firmly supported off the ground, the transmission in neutral, and the parking brake applied, unless specifically stated otherwise.*

Many adjustments call for the use of a tachometer, which is not fitted to the 750A. An automotive tach-dwell unit makes a satisfactory substitute. Readings must be adjusted. Engine rpm will be *twice* that shown on the 4-cylinder scale of an automotive tach-dwell meter, or *four times* that shown on the 8-cylinder scale.

COMPRESSION TEST

1. A compression check should be made before each tune-up since this will provide a general idea of engine condition.

2. It is necessary to have a gauge with a flexible hose and the proper screw-in adapter (plug holes are 12 mm).

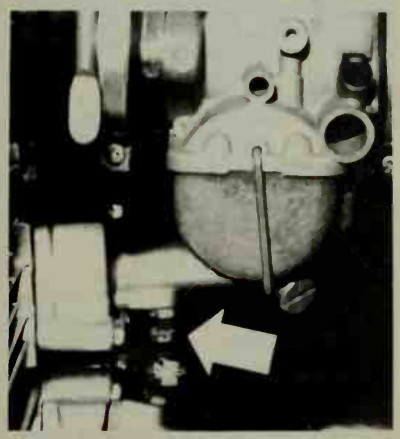
3. The engine should be at operating temperature when checking compression.

4. Remove all of the spark plugs and fit the gauge to one of the plug holes.

5. Close the choke and hold the throttle wide open while spinning the engine with the starter motor. Note the compression reading and repeat the test with the remaining cylinders.

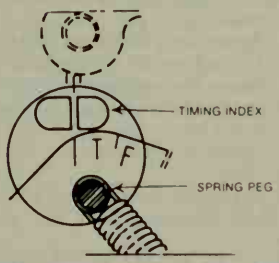
6. Compression may vary according to gauge tolerance and several other factors. However, it should normally be between 140 and 170 psi. All cylinders must be within 15 psi of this range and of each other.

CAM CHAIN ADJUSTMENT



1969–78

1. Disconnect the fuel lines from the petcock, raise the seat, and remove the gas tank.



2. Remove the points cover. Remove the valve adjuster caps from the No. 1 (left outside) cylinder, and remove all four spark plugs.

3. Using a wrench on the special nut provided for this purpose on the end of the breaker cam shaft, turn the engine over in the normal direction of rotation (clockwise as seem from the right side) until the "T" (top dead center) mark for cylinders Nos. 1 and 4 align with the timing index mark (1.4).

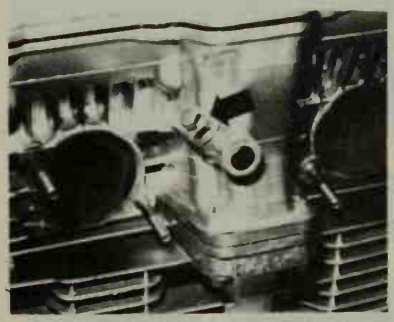
4. Check that there is clearance at both valves for the No. 1 cylinder. If not, turn the crankshaft one complete revolution (360°)

Cam chain adjustment bolt (1969–1978)

Crankshaft position for cam chain adjustment (1969–1978)

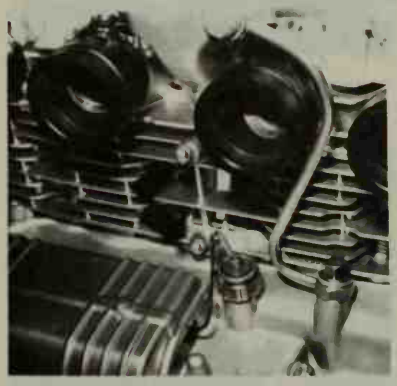
until the marks again align, and check the valves. To be effective, the chain adjustment must be performed when the No. 1 cylinder is on the compression stroke.

5. After the crankshaft has been properly positioned, continue to turn it clockwise until the spring peg on the timing advancer is just to the right of the timing index mark. In this position, cylinders 1 and 4 will be at 15° ATDC (after top dead center) and the adjustment can be performed.



CAUTION: *Do not rotate the crankshaft counterclockwise (opposite the direction of normal rotation) if you have turned it too far. Instead, rotate it clockwise through two revolutions so that the No. 1 piston will again be on the compression stroke and you can position the spring peg just to the right of the timing mark without having to turn the crankshaft back. Otherwise all of the slack may not be taken out of the chain.*

6. After positioning the crankshaft as outlined, loosen the cam chain tensioner bolt locknut and back out the bolt until you can turn it with your fingers. At this point, the tensioner bolt has released the tensioner rod, which is spring-loaded and which will move in automatically to take up the chain slack. Then tighten the tensioner bolt to 5.9–7.2 ft lbs and secure the locknut.



1979–81

The cam chain adjustment is made with the engine running. Read the procedure carefully first to cut down on the time the engine will have to idle.

1. Start the engine and let it idle.
2. Loosen the front cam chain tensioner bolt locknut. Turn the bolt out ½ turn. Tighten the bolt and secure the locknut.

Front cam chain adjustment bolt (1978–1981)

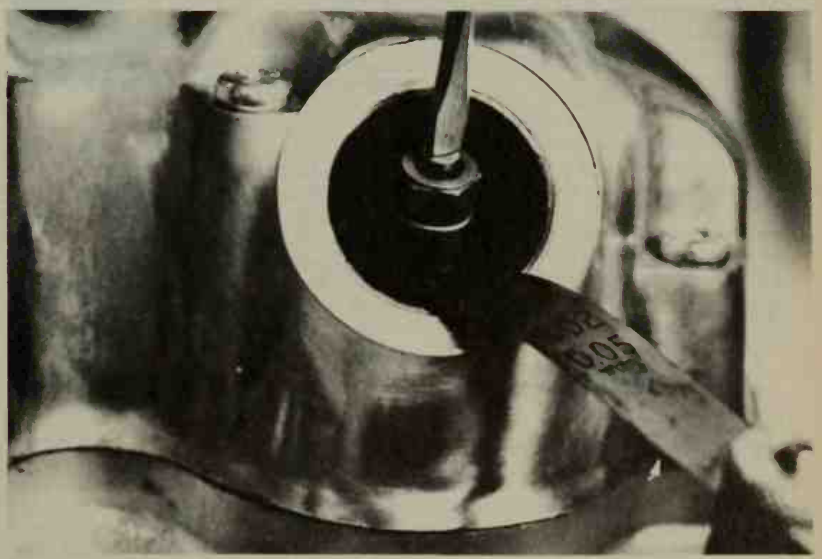
Rear cam chain tensioner bolts (1978–1981)

3. There are two cam chain tensioner locknuts behind the cylinders. Loosen both locknuts ½ turn, then tighten each one.

Cam chain tension will be set automatically when the bolt and locknuts are first loosened, then secured.

VALVE ADJUSTMENT

1969–78



In the following procedure, the cylinders are numbered 1 through 4, going from left to right from the point of view of a rider sitting on the machine. The firing order is 1-2-4-3.

NOTE: *Valves must be adjusted when the engine is COLD.*

1. Disconnect the fuel lines from the petcock, raise the seat, and remove the gas tank.
2. Unscrew and remove the valve adjuster caps from each cylinder. Remove the points cover. Remove the spark plugs.
3. Using a wrench on the special nut on the end of the contact breaker shaft, turn the engine over in the normal direction of rota-

Crankshaft position for valve adjustment: cylinders 1 & 4 at TDC

Adjusting valve clearance

tion (clockwise) and observe the valves of the No. 1 (left outside) cylinder. When the intake valve opens and then closes, the piston is approaching top dead center (TDC) on the compression stroke. Continue to turn the crankshaft slowly while observing the timing marks on the timing advancer. When the "T" 1.4 mark aligns with the index mark, check for clearance at both valves for the No. 1 cylinder. If there is clearance here, the crankshaft is properly positioned with the No. 1 cylinder at TDC on the compression stroke, and the valves can be adjusted according to the following procedure. If there is not clearance at both valves, the piston is at TDC on the *exhaust* stroke and the engine must be turned through one complete revolution until the "T" 1.4 mark again comes into alignment.

4. When the engine is properly set up as outlined in step 3, half the valves can be adjusted. These are the valves identified as "A" in the following chart:

(Looking down on the engine, from the rider's position.) Right side

Valves	No. 1 Cyl	No. 2 Cyl	No. 3 Cyl	No. 4 Cyl
Exhaust Valves	A	A	B	B
Intake Valves	A	B	A	B

5. Valve clearances are 0.05 mm (0.002 in.) (intake) and 0.08 mm (0.003 in.) (exhaust) measured between the valve stem and the adjusting screw. If the valve clearance is correct, a feeler gauge blade of this thickness will be a light slip fit. That is, there should be some resistance when pulling the blade through the valve, but not a considerable amount.

6. If the clearance is too large or too small, loosen the valve adjuster locknut and turn the adjuster so that a slip fit is obtained. Hold the adjuster in position and tighten the locknut securely (11–12 ft lbs). Recheck clearance after tightening the nut.

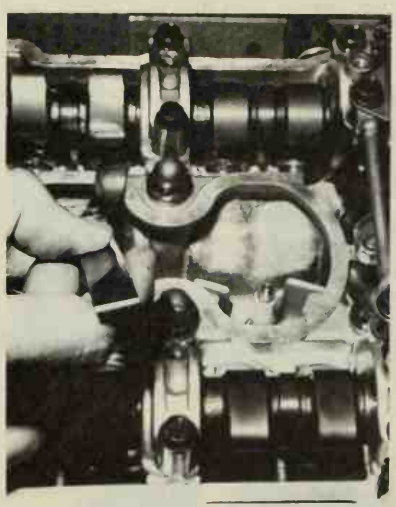
7. After all of the "A" valves are adjusted, turn the crankshaft one complete revolution (360°) until the "T" 1.4 mark again aligns with the index mark. In this position, the No. 4 (right outside) cylinder should be at TDC on the compression stroke (check for clearance at both valves) and the valves marked "B" can now be adjusted.

NOTE: *When the engine is at operating temperature, the valves should be very quiet. Ticking from properly adjusted valves is sometimes due to the valve stem becoming indented by the valve adjuster screw. This should be confined to older machines, since the valve ends are stellite-coated. Indentations on the valve stem will give a false feeler gauge reading: the clearance will be too large. Valves can be checked by visual inspection by unscrewing the adjuster.*

While more annoying than harmful, the only safe remedy for this situation is replacement of the valves.

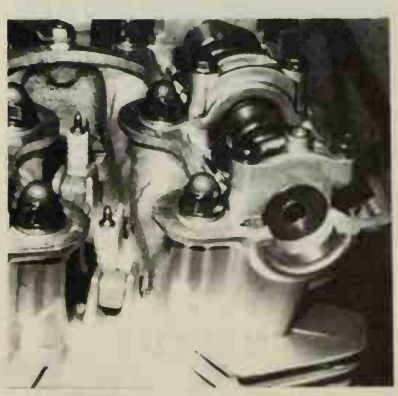
1979–81

Valve clearance can be *checked* with an ordinary feeler gauge. If *adjustment* is necessary, however, a micrometer and special valve lifter holder, as well as a selection of shims, will be necessary.



CAUTION: *We recommend that this operation be left to persons with the required tools and experience.*

CHECKING CLEARANCE



NOTE: *Valve clearance must be checked when the engine is COLD.*

1. Lean the motorcycle to the left to drain as much oil as possible from the head.

2. Remove the side covers. Raise the seat.

Checking valve clearance

Align the cam index mark with the cylinder head mating surface before checking valve clearance

3. Remove the gas tank.

4. Disconnect the tachometer cable from the cylinder head cover.

5. Remove the spark plug caps.

6. Remove the cylinder head cover bolts and take off the cover.

7. Remove the alternator cover.

8. Clearance for all valves is 0.08 mm/0.003 in.

The acceptable clearance range is 0.06–0.13 mm/0.002–0.005 in.

This clearance is measured by inserting a feeler gauge blade of the proper thickness between the cam lobe and the valve lifter shim.

A feeler gauge blade which is the proper thickness gives a light drag when pulled through the actual clearance.

The crankshaft must be properly positioned before the clearance is checked. Proceed as follows.

9. Rotate the crankshaft clockwise when viewed from the right side of the engine and align the index mark on the right side of the exhaust camshaft with the front cylinder head mating surface.

Check and record the clearances of the *exhaust* valves for Cylinder Nos. 1 and 3.

NOTE: *Cylinders are numbered consecutively 1 through 4 with No. 1 being on the left from the point of view of a rider.*

10. Rotate the crankshaft clockwise 180° (the cams will turn 90°).

Check and record the clearances of the *intake* valves for Cylinder Nos. 1 and 3.

11. Rotate the crankshaft clockwise 180°.

Check and record the clearances of the *exhaust* valves for Cylinder Nos. 2 and 4.

12. Rotate the crankshaft 180° clockwise.

Check and record the clearances of the *intake* valves for Cylinder Nos. 2 and 4.

13. If adjustment of any valve is necessary, proceed to the next section.

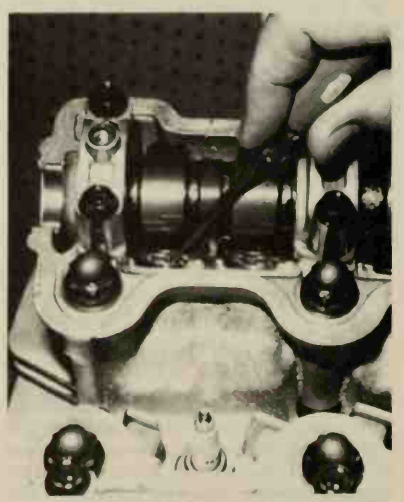
ADJUSTING CLEARANCE

1. If the measured valve clearance is not within specification (0.06–0.13 mm/0.002–0.005 in.), continue to insert feeler gauge blades between the cam and valve lifter shim to find the actual clearance. The feeler gauge blade should be a light drag when pulled through.

Record the actual clearance.

NOTE: *Valve adjustment shims are available in 0.05 mm increments from 2.30 to 3.50 mm.*

2. Rotate the valve lifter so that the notch on the lifter allows the shim to be removed.



3. Rotate the crankshaft so that the valve on which you are working is fully depressed.

4. Insert the special valve lifter holder tool between the camshaft and the two adjacent lifters.

5. Rotate the crankshaft carefully so the cam lobes turn away from the valve lifter holder.

CAUTION: *Be sure that the other camshaft does not begin to open the valves for the cylinder you are adjusting. They could hit the valves which the special tool is holding open.*

6. Remove the installed shim with a tweezers. Measure and record the thickness of this shim with a micrometer.

Turn the tappet around, if necessary, to remove the shim

Removing the adjustment shim while the valve is held open by the special tool

Measuring shim thickness

7. Refer to the valve shim selection chart.

The measured clearances run down the left side of the chart. The shim just removed can be found across the top of the chart.

To find the correct replacement shim, find the spot where the two readings meet. The shaded columns in the chart will serve as an example.

NOTE: *The thickest available shim is 3.5 mm. If a thicker shim is required to acheive the specification, there is evidently a good deal of carbon on the valve seats. A complete valve job is recommended.*

8. When the correct replacement shim is obtained, measure its thickness just to be sure.

9. Insert the new shim. Carefully turn the crankshaft so that the cam lobes will hold the valves you are adjusting fully open.

CAUTION: *Again, do not allow the lobes of the other cam to open the valves on the cylinder you are working on.*

10. Remove the special tool.

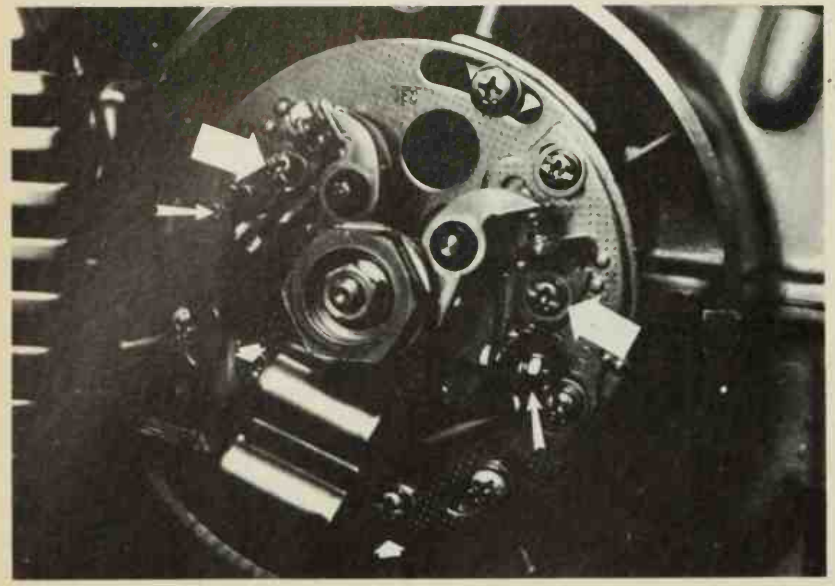
11. Rotate the crankshaft several times to seat the new shim. Recheck the clearance.

CONTACT BREAKER POINTS

Location

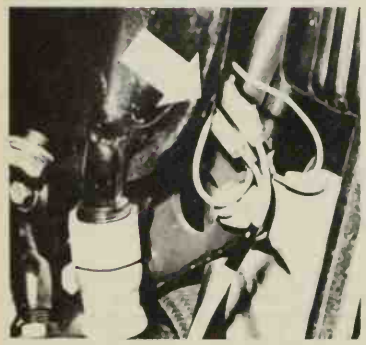
The points and condensers are located on the right end of the crankshaft beneath the chromed points cover. The timing advance mechanism is fitted onto the crankshaft behind the breaker point base plate.

Replacement



1. Points sets are available complete with condensers already mounted on the breaker plate. Removal is accomplished by removing the small 6-mm nut on the end of the breaker cam and taking off the large nut used to turn the engine over. This large nut is keyed to its shaft, not threaded. Next, disconnect the primary wires at the connectors behind the engine. Carefully pull the wires through, noting the proper routing. Remove the three screws which secure the breaker plate. When the new plate is fitted, position it so that the securing screws are approximately centered in their slots, and adjust the point gaps and the ignition timing.

2. If the points are purchased separately, disconnect the primary wire at each point set, remove the securing screw, and remove the old points. When installing new points, note that the proper installation of the insulating washers at the primary terminal is critical. If improperly installed, no spark will occur. There is a small insulating tube which fits around the terminal bolt and two insulating washers, one immediately on either side of the terminal bracket. All connectors (condenser, primary wire, points spring) are made on the outer sides of these washers (i.e., no connector must touch the bracket, which is a ground).



3. New points may have a protective coating on the contact surfaces to prevent oxidation. Clean off these surfaces with a non-oily solvent before attempting to start the machine.

1.27–1.31	3.50																								

To remove the points, disconnect the primary wires (small arrows) and remove the securing screws (larger arrows)

Point wire connectors

4. If the motorcycle will not start immediately after installation of new points, check that the primary wire connections behind the engine are tight, that the insulating washers at the primary terminal are properly installed, and that the contact surfaces are thoroughly cleaned.

5. Condensers are easily replaced after disconnecting the lead at the primary terminal and removing the screw which secures the condenser to the base plate.

Gapping

Feeler Gauge Method

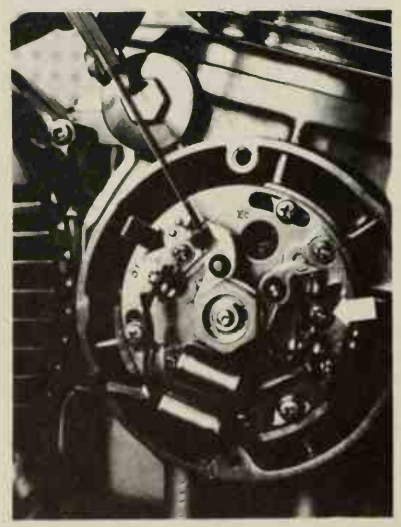
Periodic gapping is necessary to compensate for erosion of the contact surfaces due to electrical arcing and for wear of the fiber heel. As the heel wears, the points will open later relative to the rotaiton of the crankshaft, thus retarding the timing slightly.

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the points cover.

2. Using the special nut, turn the engine over until one of the two sets of points is fully open.

3. With the proper feeler gauge blade, check the gap. The proper specification is 0.3–0.4 mm (0.012–0.016 in.), and the blade should be a slip fit between the points if the gap is correct.



4. If adjustment is necessary, loosen the screw which secures the point set to its plate, and use a small screwdriver at the pry point provided to adjust the gap.

CAUTION: *Loosen the screw just enough to allow the points to be moved. If loosened too much, the points will snap shut instead of holding the gap.*

5. Tighten the screw and recheck the gap. It may change slightly when the screw is tightened.

6. Repeat the procedure with the remaining points set. Try to adjust both sets so that the feeler gauge blade has the same "feel" in both sets. This will help to ensure accurate timing.

7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the points should then be replaced.

Checking point gap. Loosen the securing screws (arrows) to adjust the gap

DWELL METER METHOD

Point gap can also be adjusted with the aid of a dwell meter if one is available. "Dwell" is the amount of time the points are closed relative to crankshaft revolution and is expressed in degrees.

The adjustment is made with the engine idling, the positive meter connections lead to the primary wire terminal, and negative lead to the engine (ground).

With the meter set to the "8 cylinder" range, the proper dwell specification will be 23.75°; if set to the "4 cylinder" range, it will be 47.5°.

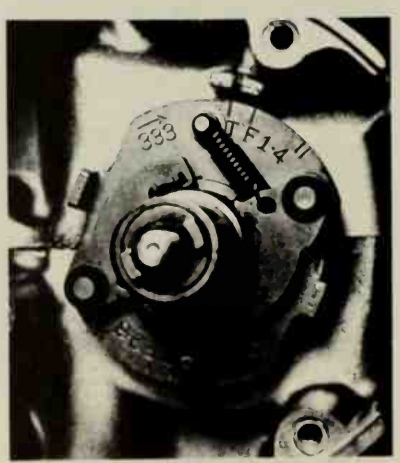
Increasing the point gap will decrease the dwell reading, and vice-versa.

Lubrication

1. On all models it is necessary to occasionally lubricate the cam follower fiber heel and the pivot point of the contact breaker. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.

2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.

3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.



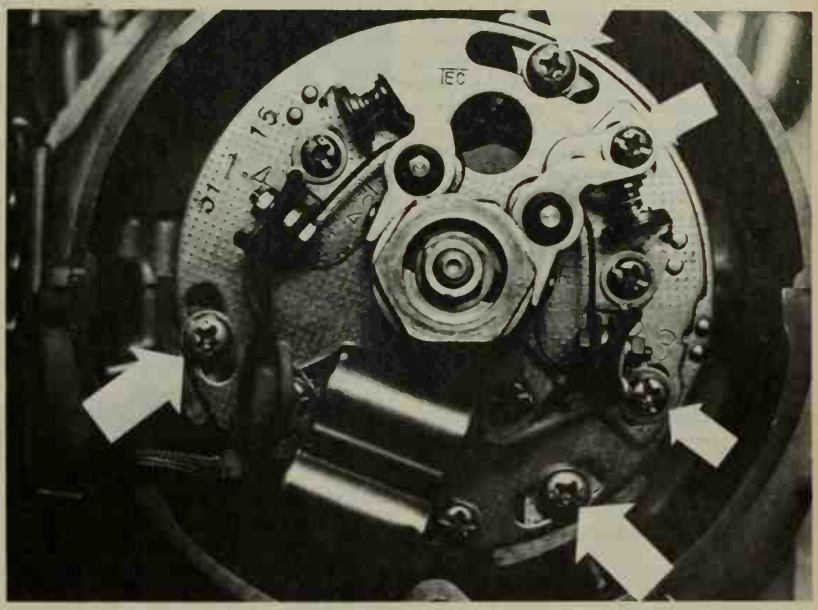
4. The lubricating wick should be adjusted so that it just contacts the breaker cam.

IGNITION TIMING

1969–78

The timing advance mechanism behind the breaker plate is fitted with marks which indicate piston position when they are aligned with the stationary timing mark (visible through the inspection hole in the breaker plate). There are two sets of marks, identified 1.4 and 2.3 to indicate which cylinders they represent.

The timing marks on the advance mechanism are interpreted as follows: "T" indicates top dead center, "F" is the fixed advanced firing point, which is when the plug fires



Automatic advance mechanism timing marks

before the automatic timing advancer comes into play and is about 10° BTDC. An additional pair of marks indicates the full advance firing point, which is 33°–36° BTDC above 2500 rpm.

NOTE: *Points must be cleaned and gapped before checking timing. Dirty points will cause inaccurate readings.*

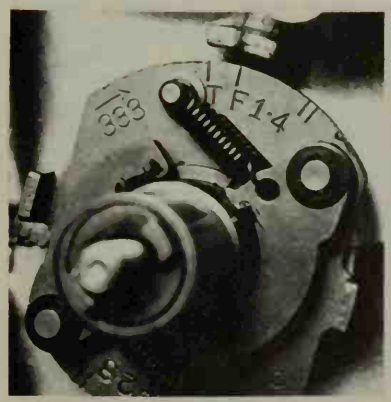
Observing the breaker plate, note that the points set on the left are marked "1.4." They control the timing for those two cylinders, and are secured to the large base plate. The righthand points, marked "2.3," are mounted on a smaller moveable plate. Therefore, cylinders 1 and 4 are set first, and the timing for this pair is adjusted by rotating the entire base plate. Obviously, this will affect the timing of the remaining cylinders. The latter are adjusted, if necessary, by moving only the points themselves as they have slotted fittings for this purpose.

Loosen the three screws (larger arrows) and rotate the braker plate to adjust the timing for cylinders 1 & 4. Loosen the two screws (smaller arrows) and move the breaker points to adjust the timing for cylinders 2 & 3

DYNAMIC TIMING

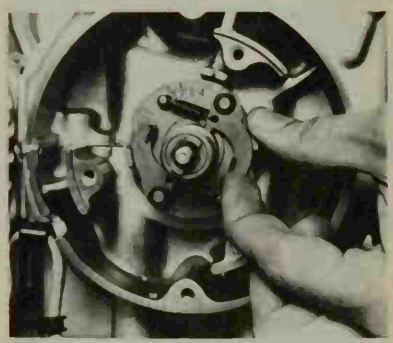
1. Clean and gap both sets of points as described previously.
2. Hook up the strobe light according to the directions of the light's manufacturer to pick up the impulses from the No. 1 (left outside) cylinder.
3. Start the engine and adjust the idle, if necessary, to the recommended idle speed.
4. Aim the light at the timing marks visible through the inspection hole in the points base plate. At idle, the "F" mark should align with the timing index mark.
5. To check ignition timing at full advance, increase the engine speed until the motor is turning 2,500–3,000 rpm. At this point, the timing index mark should be between the two full advance marks scribed into the timing advance mechanism.
6. If adjustment is necessary, carefully loosen the three base plate screws and rotate the plate so that the proper marks align at the specified rpm. Establishing this alignment at full advance is recommended. Tighten the base plate screws.
7. Repeat the procedure, this time having the strobe light pick up cylinder No. 2. If adjustment is necessary, loosen the two screws which secure points set 2.3 to its plate, and use a small screwdriver at the pry point provided to move the set so that proper mark alignment is achieved. Tighten the screws.

Full advance firing point aligned with timing mark (breaker plate removed for clarity)



8. If it is not possible to achieve full advance alignment without moving the base plate or points set 2.3 all the way to the end of their range of allowable travel, it is possible that the points are either incorrectly gapped, or that they are worn to the point where they must be replaced.
9. If other troubles are encountered, see "Troubleshooting" below.

STATIC TIMING



1. Connect one of the test light or tester leads to the primary wire terminal for the points set "1.4." Ground the other lead to the engine.
2. If the test device is not self-powered, turn the ignition switch *on* and be sure the kill switch is in the "on" position as well.
3. Turn the engine over in the normal direction of rotation until the "F" mark or cylinders 1 and 4 align with the timing index mark. The test instrument should react at the instant these marks align, indicating that the points have opened. If they do not, loosen the three base plate screws and rotate the base plate so that the points just open when these timing marks are in alignment. Moving the base plate clockwise will retard the timing, counterclockwise will advance it.

Cylinders 1 and 4 are now correctly timed. Tighten the base plate screws and recheck.

4. Repeat the procedure with points set 2.3. If adjustment is necessary, loosen the two screws which secure these points to their mounting plate and use a small screwdriver at the pry point provided. Tighten the screws and recheck the timing.

Fixed advance (F) mark aligned with timing mark

Checking the operation of the automatic timing advance mechanism

TROUBLESHOOTING

1. If the static method is used, the reaction of the test light or meter should be positive when the points open. If the instrument seems to hesitate before indicating that the points are open, it may be because of defective condensers or dirty or pitted points surfaces.
2. If it is necessary to move the base plate or the points plate to the extreme end of the adjustment range to effect proper timing, the points or points heel is probably worn to the limit, and the set should be replaced.
3. If the dynamic method is used, the various timing marks should hold their positions steadily to given rpms. If they seem to

move erratically, check the condition of the timing advance mechanism behind the base plate. Check for weak or broken springs or stiff movement of the advancer weights. When the breaker cam is turned so that the weights move outwards, and then is released, it should return to the original position. If it does not, the springs are too weak and must be replaced. Try penetrating oil or a spray parts easer to ease movement of the mechanism if it is stiff. If this fails, replace the mechanism.

4. If the advancer shaft is bent, which will be noticeable as the engine is turned over, remove the advance mechanism and bend the shaft so that total run-out is no more than 0.1 mm (0.004 in.). To remove the advancer mechanism, pull it off by grasping the plate, not the breaker cam. If the cam disengages from the plate, it is possible to reinstall it incorrectly.

When installing the advancer unit, make sure that the pin is fitted into the locating hole.

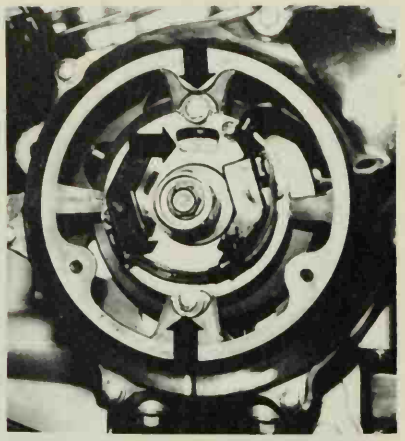
1979–81

The ignition system on these models is transistorized, and should therefore be trouble-free. Once set properly, the timing should not need readjustment.

An automotive timing light is the only accurate method of checking the timing. It allows the timing to be checked at idle as well as at full advance. There is, however, a crude static method (given below), but the accuracy of this check is problematical.

It is recommended to either use a strobe light or leave the timing alone.

1. Park the motorcycle on the centerstand in a well-ventilated area. Remove the pulser generator cover (left side).



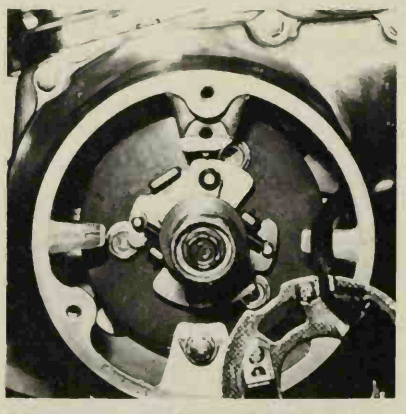
Pulser generator cover screws

2. Connect the strobe light to the No. 1 (left) cylinder.

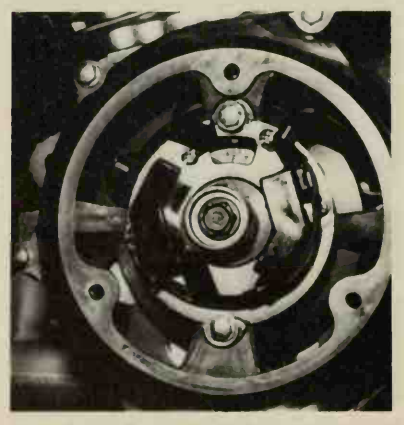
3. Start the engine and allow it to idle at about 1,000 rpm.

4. Check the timing marks through the window in the base plate. At about 1,000 rpm, the "1.4 F-I" mark on the timing advance mechanism should align with the index mark.

5. If the marks do not align, loosen the two large phillips screws or bolts at the top and bottom of the base plate just a bit, and turn the plate so that the marks are lined up. Tighten the two screws securely and recheck the timing.



Timing marks and timing adjustment bolts



Turning the plate clockwise will advance the timing, while counterclockwise rotation will retard it.

6. Full advance timing is not acheived until 6,000 rpm. Since engine damage may result on an unloaded engine at 8,000 rpm, the full advance check should only be carried out by someone with experience.

7. The full advance timing marks are two slash marks which, as noted, should align with the timing index mark at 6,000 rpm. If idle timing is correct, but full advance timing is not, the only trouble can be the timing advance mechanism. See "Troubleshooting," below.

Full advance marks aligned with index mark

Static timing alignment (arrow)

8. The static timing method is simple. Remove the generator cover. Rotate the crankshaft counterclockwise and align the "1.4 S-F" mark with the timing index mark. If the timing is correct, the narrow projection of the "1.4" pulser generator (the one of the left) will align with the rotor tooth. Adjustment is made by loosening the two large phillips screws or bolts at the top and bottom of the base plate and rotating the plate so that alignment is accomplished.

NOTE: *Either No. 1 or No. 4 cylinder must be on the firing stroke when the check is made. If alignment is not obvious, rotate the crankshaft 360° and recheck.*

Checking advance mechanism operation

TROUBLESHOOTING

Due to the nature of the system, any malfunction as regards spark or lack of same must be due to electrical causes.

If the timing marks align at idle speed, but not a full advance, the trouble is probably the timing advance mechanism located behind the pulser base plate.

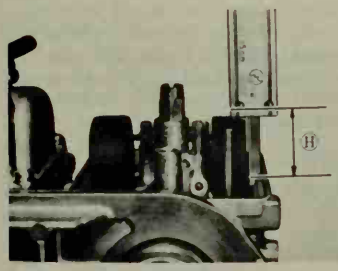
The various timing marks should hold their positions steadily at any given rpm. If they seem to move erratically, this is also probably due to the advance mechanism.

After removing the pulser base plate, check the timing advance mechanism for weak or broken springs or stiff movement of the advancer weights. When the breaker cam is turned so that the weights move outwards, and then is released, it should return to the original position. If it does not, the springs are too weak and must be replaced. Try penetrating oil or a spray parts easer to ease movement of the mechanism if it is stiff. If this fails, replace the mechanism.

CARBURETORS

Carburetor adjustments to be made during a tune-up procedure include checking float level, idle speed, and mixture; carburetor synchronization; and travel limit adjustments.

CAUTION: *These adjustments should be made only in a well-ventilated area.*



To avoid engine damage due to an overheated engine, read the procedures several times before beginning. A large household

window fan, positioned near the front of the engine, may help to keep engine temperature down during these adjustments.

Adjusting Float Level

Float level is a measure of the amount of gasoline which will be in the float bowls during operation. While it is a critical specification, it will not normally need readjustment once properly set. Float level, therefore, need not be checked at every tune-up, but should be attended to from time to time.

1. Remove the carburetors as outlined in "Fuel Systems."
2. Remove the float bowls. With the carburetor(s) positioned horizontally, lower the

Measuring float height (H)

Increase float height by bending the tang towards (B); decrease it by bending towards (A)

float until the float arm just touches the tip of the float needle. Float level is the measured distance from the bottom of the float to the float bowl mating surface.

NOTE: *A special float level gauge (part No. 07144-99998) is available to facilitate this task.*

3. Compare the measured float level with the standard value given in the "Tune-Up Specifications" chart at the end of this section. Adjust, if necessary, by removing the float assembly and carefully bending the float arm tang. Bending the tang towards the carburetor body will increase the float level measurement, and vice-versa.
4. All carburetors must have the same float level. Measure all before changing any. Note that the measured float level will be inaccurate if the float needle tip is worn, or if there is foreign matter on the needle seat.

750 Pre-K Models

IDLE SPEED, MIXTURE, SYNCHRONIZATION

NOTE: *The following adjustments must be made when the engine is at operating temperature. Other tune-up operations (valve adjustment, ignition timing, etc.) should be performed first.*

1. Remove the air cleaner box and the gas tank.
2. Engage the choke. Check the clearance between the choke valve and the carburetor body for each unit. If the clearance is greater than 0.5 mm (0.02 in.), adjust by means of the variable length rods which connect the choke valves. After this adjustment, disengage the choke.
3. Adjust the throttle stops screws on each carburetor so that the "T" marks on the screws align with the index marks on the carburetor bodies.
4. Adjust each of the short throttle cables so that each has 1–2 mm (0.04–0.08 in.) of free-play before the slide(s) begin to lift. Use the cable adjuster atop each carburetor to make this adjustment, and try to adjust each carburetor so that the free-play of all the cables are as near to one another as possible.
5. Gently turn in the pilot screw on each carburetor until it is seated, then back each out one full turn.
6. Install the air cleaner and gas tank. At this point it would be helpful if the rear of the tank were propped up. The use of longer fuel lines will be necessary. Be sure the tank has a good supply of fuel.

For the following adjustments the engine must be fully warmed up.

7. Attach the vacuum gauge fittings to each of the carburetors. Start the engine and adjust the idle speed, if necessary, to 850–950 rpm by turning the throttle stop screws out in small equal increments. The gauges should read about 20–22 cm Hg. Lowering the idle speed will increase the vacuum and vice-versa. All cylinders must be within 3.0 cm (1.2 in.) Hg of each other. Use the throttle stop screws to equalize the pressure, if necessary.

NOTE: *Some vacuum gauges are equipped with adjustable dampers to eliminate needle oscillation. Do not overdampen the needles. A fluctuation of about 1 graduation of the scale is acceptable.*

8. If the pressure is below 15 cm (0.59 in.) Hg, check for sticking or improperly adjusted valves, lack of free-play in the throttle cable(s), loose spark plug(s), or air leaks at the manifolds.
9. Turn each pilot screw alternately in either direction about ⅛ turn at a time (pausing for a few seconds after each change) to determine the point at which the highest engine rpm is reached. It should not be necessary to turn the screws *out* more than 1 turn, nor *in* more than ½ turn from the standard setting. If it is, check the following:

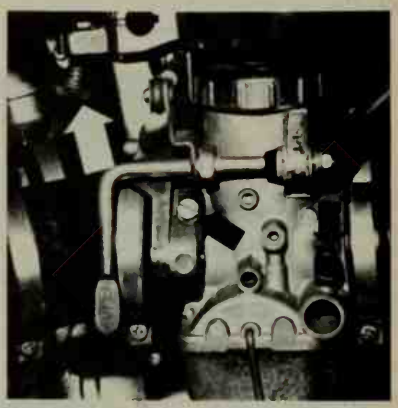
a. If the screw must be turned more than 1 additional turn out: clogged air passage, worn or damaged air screw taper, loose pilot jet, or float level set too high.

b. If the screw must be turned more than ½ turn in: obstructed pilot jet or jet passage, worn or damaged pilot air screw seat, too low a float level.

10. Synchronize the throttle slides as follows: hold the throttle open about ¼ of the twist-grip rotation for about 30 seconds. All cylinders should show the same vacuum gauge reading within 3.0 cm (1.2 in.) Hg.

Correct any variation by means of the cable adjusters atop each carburetor. Increase the vacuum gauge reading by screwing the adjuster *in* and vice versa.

11. After all the cylinders have been equalized, snap the throttle open and shut a few times and recheck the adjustment. Be sure the cable adjuster locknuts are secured and the rubber caps refitted.
12. Adjust throttle cable free-play at the twist-grip, if necessary. Turn the forks slowly from side to side with the engine running to ensure that engine speed doesn't change, which would indicate badly adjusted or kinked cables.



NOTE: *During this procedure, do not allow the engine to overheat by idling for long periods of time while stationary. An ordinary household window fan can be used to blow air over the engine if the adjustment time takes longer than about five minutes.*

750K1–K5, 750 (76), 750F (75–76)

These adjustments must be made when the engine is at operating temperature. Other tune-up operations (valve adjustment, ignition timing, etc.) should be performed first.

SYNCHRONIZATION

1. Raise the rear of the fuel tank as far as the fuel lines will allow and support the tank in this position. It may be helpful to temporarily fit longer fuel lines so that the tank can be raised higher.
2. Slide the rubber boots on the carburetor tops back on the linkage arms.

Throttle idle adjusting screw, pilot screw (right) and vacuum gauge fitting (center)

Throttle rod adjustment nut

3. Connect the vacuum gauge tubes to the carburetors.

4. Start the engine and adjust the idle speed with the throttle stop screws to about 1,000 rpm.

5. Loosen the adjuster nut locknuts and turn the adjuster nuts until all carburetors are indicating uniformly (within 3.0 cm Hg) between 16–24 cm Hg. Turning the adjuster nuts clockwise increases vacuum, and counterclockwise decreases vacuum. Try not to increase the idle speed while making adjustments.

NOTE: *Some vacuum gauges are equipped with adjustable dampers to eliminate needle oscillation. Do not overdampen the needle. A fluctuation of about one gradation on the scale is acceptable.*

CAUTION: *Do not allow the engine to overheat by idling it for long periods while stationary. A household electric window fan can be used to provide a flow of air over the engine to prevent overheating when adjustment time exceeds more than about five minutes.*

6. After adjustment has been made, check to see that at least one thread on each throttle rod protrudes above the locknuts. If not, turn all four adjuster nuts in an equal amount until at least one thread on each throttle rod is exposed, reset the idle speed with the throttle stop screw, and recheck the vacuum readings.

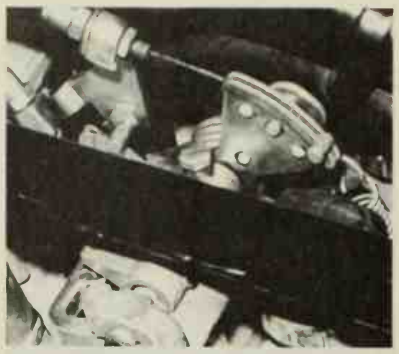
7. Snap the throttle open several times to verify synchronization before tightening the locknuts.

CAUTION: *When tightening the locknuts, hold the adjuster nut in position with a wrench to prevent the torque from being transferred through the throttle rod and twisting it off. Tighten the locknuts to 11–17 in. lbs, or about 1 ft. lb. Do not overtighten.*

8. When refitting the rubber boots, make sure that the bottom rim is fully seated in the groove at the base of the adjuster linkage. It is a good idea at this time to open the throttle wide to expose the throttle rods and lubricate the rods and adjuster linkage with silicone grease. *Do not use a petroleum-based lubricant.* The throttle shaft pivots may be lubricated with motor oil.

IDLE ADJUSTMENT

Adjust the carburetor pilot screws so that the maximum vacuum draw is obtained, consistent with engine smoothness. Standard pilot screw adjustment range is ¾–1¼ turns from the fully closed position. Readjust the throttle stop screw, if necessary, to reduce idle speed to about 1,000 rpm. Recheck vacuum uniformity and idle smoothness. Remove the vacuum gauge tubes and tighten the carburetor plugs firmly.



THROTTLE CABLE ADJUSTMENT

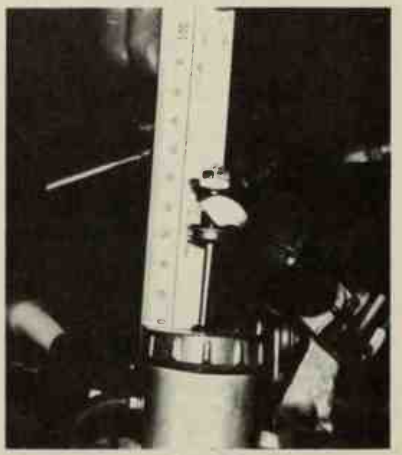
Play Adjustment

1. Back off the cable adjuster at the handlebar to increase cable play. Leave a small amount of adjustment range available so that final, small adjustments can be made.

2. Loosen the cable locknut at the carburetor end and turn the adjuster until there is about 3–4 mm (0.12–0.17 in.) play at the throttle grip. Retighten the locknut.

NOTE: *The throttle lever should hit the eccentric pin when the throttle grip is forced to the fully closed position. If the lever will not hit the pin, replace the return cable.*

Clearance is measured between the eccentric pin (arrow) and the lever



3. Make any desired final cable play adjustment at the handlebar adjuster.

Overtravel Limit Adjustment

Simply loosen the locknut and turn the eccentric pin, as shown, until clearance between the pin and the throttle lever is 2–3 mm (0.08–0.12 in.).

Full Throttle Limit Adjustment

Adjust the throttle lever stop screw so that there is a distance of 32.5–33.0 mm (1.28–1.29 in.) between the carburetor top and the bottom of the adjuster linkage with the throttle fully open, as shown.

Checking full throttle limit adjustment

Throttle Rod and Linkage Lubrication

Lubricate the throttle rods and seals, and the linkage pivot points, as shown in the illustration. If this does not restore smooth throttle operation, the carburetor tops should be removed, the throttle components thoroughly cleaned and dried, and the throttle rod guides and seals lubricated with silicone grease. *Do not use a petroleum-based grease.*

750A

The following operations should be accomplished with the engine at operating temperature, except for setting the fast idle, which is performed on a cold engine. Other tune-up operations (valve adjustments, ignition timing, etc.) should be performed first.

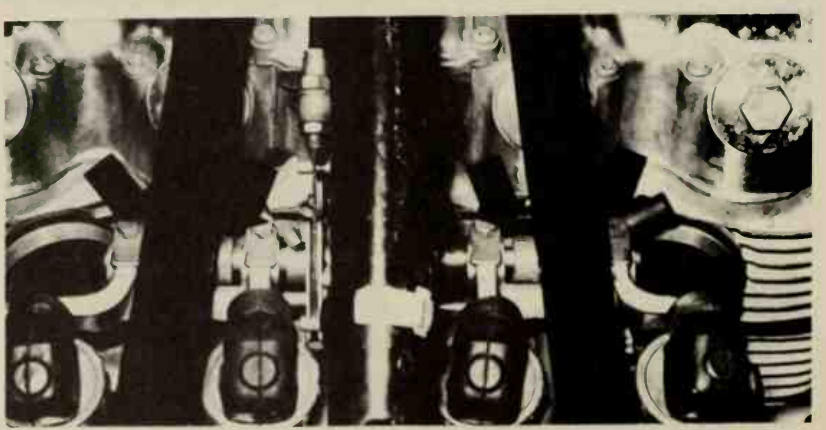
SYNCHRONIZATION

1. Remove the gas tank, supporting it out of the way and higher than the carburetors so that access to the carburetor caps is simplified. Fit longer fuel lines so that the carburetors can be supplied. Connect the vacuum gauges. Connect the tachometer.

2. Start the engine and allow it to idle. Readings of all four gauges should be the same.

3. If vacuum gauge readings differ, remove the caps from the carburetors for cylinders Nos. 1, 3, and 4. The No. 1 cylinder is on the left from the rider's point of view.

4. Loosen the locknuts and turn the adjusters so that each carburetor yields the same vacuum reading as No. 2.



5. Adjust idle speed.

IDLE ADJUSTMENT

1. Engine must be at operating temperature. With the tachometer connected, adjust the throttle stop screw to yield an idle speed of 1,000 rpm. Transmission should be in "N."

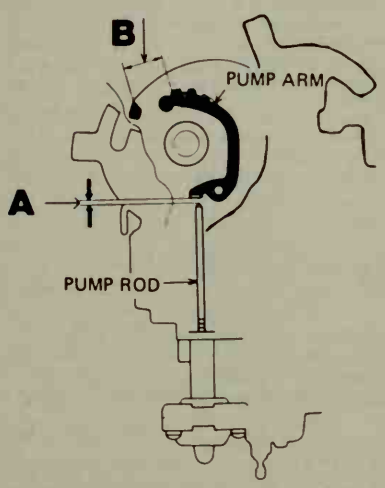
2. With the machine on the center stand and the parking brake engaged, gently turn in the pilot screws until seated, then back off until the highest idle speed is reached, which should be about 1¼ ± ¾ turn from the seated position.

3. Readjust the throttle stop screw to give an idle speed of 1,000 rpm.

Linkage lubrication points

4. Shift the transmission into "L" or "D." If idle speed drops, adjust the throttle opener.

THROTTLE OPENER



1. The engine must be at operating temperature, on the center stand, and with the parking brake engaged. Connect a tachometer. Raise the rear of the gas tank to allow access to the adjusting screw.
2. With the transmission in "N," adjust idle speed to 1,000 rpm using the throttle stop screw.
3. Shift into "L" or "D." If idle speed varies, bring it back to 1,000 rpm using the throttle adjusting screw. Refer to the illustration. Shift into neutral and recheck the idle speed.

FAST IDLE

1. Fast idle speed is 3,000–4,000 rpm. Adjustment is made on a cold engine.
2. To adjust, pull the choke lever fully open. Turn the fast idle screw in until it just contacts the choke cam.
3. Release the choke and turn the fast idle screw an additional 2½ turns. Tighten the locknut.
4. Start the engine (cold), engage the choke and check idle speed.

ACCELERATOR PUMP

1. Two adjustments are necessary: the pump-rod-to-pump-arm clearance, and the pump-arm-to-carburetor-stay clearance.
2. With the throttle closed, check clearance between the pump rod and the pump arm (A). It should be 0.6–0.8 mm (0.024–0.032 in.). Adjust, if necessary, by

Accelerator pump adjustments: A, pump rod and pump arm; B, pump arm and carburetor stay

bending the pump arm tongue very carefully.

3. With the throttle closed, check the clearance between the pump arm and the carburetor stay (B). It should be 10.0–10.5 mm (0.39–0.41 in.). Adjust, if necessary, by carefully bending the pump arm.

750K, 750F (1977–78)

These models are fitted with the newer type of carburetor similar to those of the 750A, and synchronization and idle speed adjustments are performed in the same manner with the obvious exception that all adjustments are made with the transmission in neutral with no need to worry about idle speed in gear. Also, there is no fast idle adjustment. Refer to the "750A" section for procedures.

750K, 750F (1979–81)/900C/F

These adjustments must be made when the engine is at operating temperature. Other tune-up operations (valve adjustment, ignition timing, etc.) should be performed first.

IDLE ADJUSTMENT

The pilot screws are pre-set. No adjustment is necessary unless the carburetors have been disassembled.

If adjustment is necessary, proceed as follows.

1. Turn each pilot screw in until it is lightly seated, then back each one out the following number of turns depending on the carburetors fitted:

VB42A: 1½ turns
VB42C: 1¾ turns

CAUTION: *Take care when screwing the pilot screws in. Damage to the tips may result if they are overtightened.*

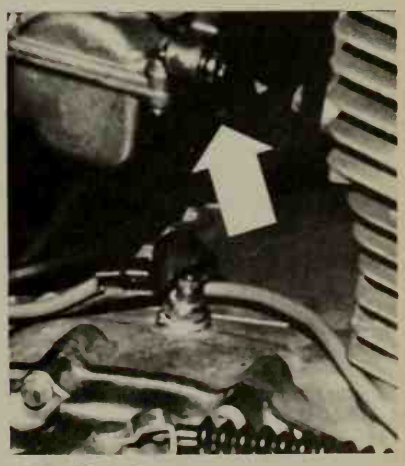
2. When the engine is at operating temperature, adjust the idle speed with the throttle stop screw. Idle speed is 900–1,100 rpm.
3. Turn each pilot screw out ½ turn. If engine speed increases by 50 rpm or more, turn each screw out an additional ½ turn.
4. Readjust the idle speed with the throttle stop screw.
5. Turn the pilot screw for the No. 1 carburetor *in* until engine speed drops by 50 rpm.

Throttle idle adjusting screw

6. At this point, turn the No. 1 carburetor pilot screw *out* by ⅜ turn on VB42A units or ¾ turn on VB42C models.
7. Readjust idle speed with the throttle stop screws.
8. Repeat Steps 6 and 7 on the other carburetors.
9. Make final idle adjustment with the throttle stop screw so that the machine idles at 900–1,100 rpm.

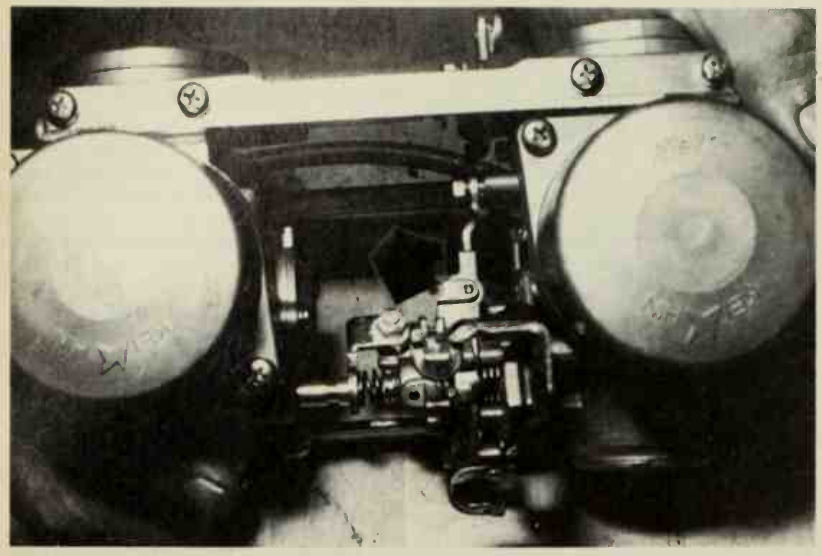
SYNCHRONIZATION

A set of vacuum gauges is needed for carburetor synchronization. In addition, longer fuel lines will be needed, since the gas tank must be removed to allow access to the adjustment screws.



1. Remove the side covers and raise the seat.
2. Disconnect the fuel line and remove the gas tank. Connect the longer fuel line, and position the tank so that it is out of the way of the adjusting screws, but can still feed gasoline to the carburetors.

CAUTION: *Be sure that the gas tank is properly secured.*



3. Remove the plugs on the manifolds and install the vacuum gauge adaptors.
4. Start the engine. Set idle speed to 900–1,100 rpm.
5. All carburetors should give vacuum gauge readings within 2.4 in. Hg (6.0 mm Hg) of each other.
6. The No. 2 carburetor cannot be adjusted. The reading for this carburetor must be taken as the standard, and all others adjusted to it.
7. To equalize vacuum readings, loosen the adjusting screw locknuts, and turn the screws so that the vacuum for all four carburetors is as close as possible. Tighten the locknuts.
8. Rev the engine a few times and recheck vacuum readings. Readjust the idle speed if necessary.

Vacuum source on manifold

Idle speed screw

Carburetor synchronization screw

FAST IDLE

Fast idle should be 1,500–2,500 rpm. This reading is taken when the engine is *cold*.

1. Close the throttles and open the choke valve. Measure the clearance between the throttle link and the fast idle adjusting arm pin.

It should be 0.7–1.0 mm/0.03–0.04 in.

2. Adjust the fast idle, if necessary, by opening and closing the fork end of the fast idle adjusting arm.

ACCELERATOR PUMP

1. Measure the clearance between the accelerator pump rod and adjusting arm with the throttles closed. It should be 0–0.04 mm/0–0.0016 in.

2. This adjustment is made by bending the adjusting arm.

3. Measure the clearance between the adjusting arm and the stopper on the carburetor body. Clearance should be 3.1–3.3 mm/0.12–0.13 in. Adjust by bending the adjusting arm.

ENGINE AND TRANSMISSION

NOTE: *Engine rebuilding techniques and procedures are explained in detail in the "General Information" section.*

NOTE: *Be sure that bolt and nut threads are clean and undamaged before torquing. Torque readings apply to clean, dry threads unless otherwise noted.*

Engine Service

1. To remove the cylinder head, barrels, and pistons, the engine must be removed from the frame, on all models except the 750A. On 1979–81 models, the cams can be removed and installed with the engine still in the frame.

2. Crankcase cover components: oil pump, clutch, gearshift mechanism, alternator, and countershaft sprocket, are all accessible with the engine in the frame. Be sure to note the locations of oil guide pins and o-rings in the crankcase covers, cylinder head, and cylinder.

3. Read each procedure carefully before beginning so that replacement items such as

ENGINE REMOVAL AND INSTALLATION

1969–78 (Except 750A)

The following components can be serviced or replaced without removing the engine from the frame: oil pump, clutch, alternator, starter drive, cam chain tensioner, and gearshift linkage.

1. Turn the fuel tap off, disconnect the fuel lines, and remove the tank.
2. Drain the oil from the crankcase and oil tank, and remove the oil filter.
3. Remove the exhaust system.
4. Disconnect the tachometer cable from the cylinder head and remove the wires from the spark plugs.
5. Unscrew the carburetor caps and withdraw the slides (early models) or disconnect the throttle cables from the carburetor linkage (K1 and later).
6. Remove the air filter housing, disconnect the carburetors from the intake tubes, and remove the carburetors as an assembly.
7. Remove the kick-start lever and the clutch housing cover. Disconnect the clutch cable from the clutch lever.
8. Disconnect the brake-light switch spring and remove the brake pedal and footpeg.
9. Unbolt the two oil lines from the engine and remove the oil tank. Disconnect the oil tank breather line from the upper crankcase.
10. Remove the shift lever and take off the engine sprocket (rear crankcase) cover. Loosen the rear axle nut and drive chain adjusters so that the wheel can be moved forward and the chain can be lifted off the rear wheel sprocket. Remove the engine sprocket.
11. Disconnect the positive battery cable, then disconnect the starter motor cable at the solenoid, the alternator lead at the connector near the battery, and the brake light switch lead at the upper, right-side, rear motor mount.
12. Remove the engine mount bolts, as illustrated. Raise the rear of the engine and lift it out from the right side of the frame.

Installation is in reverse order of removal. The following points should be noted:

a. Be sure to connect the battery ground strap to the upper, rear engine-mount bolt as the bolt is installed.

b. Torque all mounting bolts to the proper specification. Refer to the "Torque Specifications" chart at the end of this section.

c. Take care to connect the scavenge and delivery oil lines in their original positions.

d. Make sure that the muffler connecting clamps are in place on each pair of mufflers.

e. When installation is complete, refill the engine with oil. Adjust the clutch, drive chain, and carburetors.

750A

It is possible to remove the cylinder head, barrels, and pistons without removing the engine from the frame. The alternator, torque converter, oil pump, transmission oil pump, and shift mechanism are also accessible.

1. Drain the oil. Shut off the fuel petcock, disconnect the fuel lines, and remove the gas tank.
2. Remove the left and right side covers. Remove the air cleaner box. Disconnect the carburetor overflow tubes. Disconnect the throttle cables and choke cable. Loosen the carburetor clamps and remove them together.
3. Disconnect the spark plug leads from the plugs.
4. Remove the rear brake pedal, the left and right footpegs, the shift lever, and the right-side passenger peg.
5. Remove the exhaust system.
6. Disconnect the wiring at the connectors on the right-side.
7. Disconnect the neutral return arm and the wiring connectors on the left side. Remove the engine sprocket cover. Loosen the rear wheel axle nut, back off the chain adjusters, and move the wheel forward. Unbolt and remove the engine sprocket.
8. Remove the oil filter and housing. Remove the oil pan and remove the oil screen from the engine oil pump.
9. Remove the engine mounting bolts and take the engine out from the left side of the machine.

Installation is the reverse of removal. Note the following points:

a. Be sure the battery negative cable is properly attached to its mounting bolt.

b. Tighten engine mounting bolts to the proper torque:

10 mm: 22–29 ft. lbs.
12 mm: 40–47 ft. lbs.

c. Check engine oil level, chain tension, etc., before starting the engine.

750 (1979–81)

1. Drain the oil. Remove the side covers. Raise the seat and disconnect the overflow tube.
2. Disconnect the fuel line at the fuel tank, and remove the tank.
3. Remove the air cleaner box and the carburetors.
4. Disconnect the wiring at the plastic connectors.
5. Remove the exhaust system.
6. Disconnect the spark plug caps from the plugs. Disconnect the tach cable at the head.
7. Push the rear wheel forward as much as possible after loosening the rear axle nut and folding down the chain adjusters. Remove the left rear crankcase cover. Unbolt and remove the engine sprocket along with the chain.
8. Remove the rear brake pedal. Remove the rider footpegs. Remove the gearshift lever. Disconnect the clutch cable at the engine.
9. Place a jack beneath the engine and raise it just slightly to get the engine weight off the mounting bolts. Remove the engine mounting bolts and plates and move the engine out of the frame towards the right side.

Installation is the reverse of removal. Note the following points:

Tighten engine mounting bolts to the proper torque values:

8 mm flange bolt/nut: 13–18 ft. lbs.
10 mm flange bolt/nut: 22–29 ft. lbs.
12 mm flange bolt/nut: 40–47 ft. lbs.

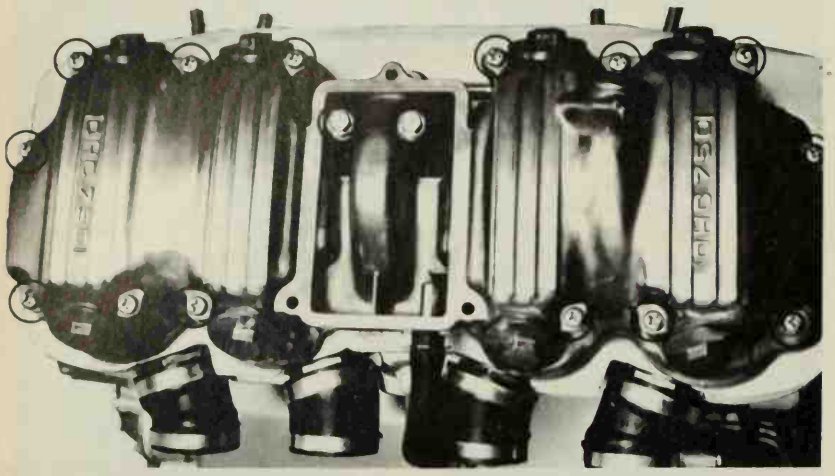
Tighten the engine sprocket bolt to 24–27 ft. lbs.

Be sure that all wires and cables are properly arranged and secured by clamps or cable ties where applicable.

After installation, adjust the throttle and clutch cables, choke cable, and drive chain tension.

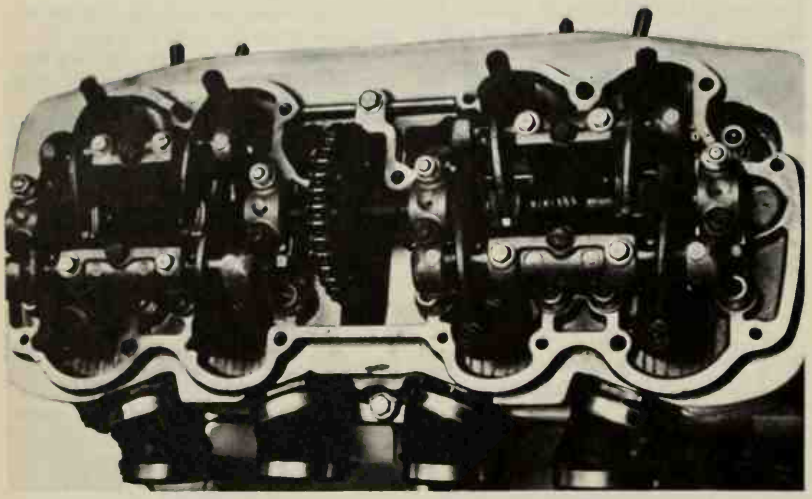
900

1. Drain the oil. Remove the left and right side covers.
2. Remove the gas tank and seat.
3. Remove the side stand.
4. Remove the exhaust system.
5. Disconnect the oil cooler hoses from the engine.
6. Remove the air cleaner assembly and the carburetors.
7. Disconnect the tach cable at the engine. Disconnect the spark plug caps.
8. Disconnect the wiring at the couplers. Disconnect the starter motor cable and the battery negative cable.
9. Remove the brake pedal. Remove the brake pedal bracket lower mounting bolt and loosen the upper bolt.
10. Remove the clutch cable holder.
11. Remove the rear wheel. Remove the final drive gear. Move the swing arm boot back and disengage the drive shaft from the engine.
12. Place a jack beneath the engine to take the weight off the mounting bolts. Remove the mounting bolts and brackets and take the engine out of the frame from the left side.
13. Installation is the reverse of removal. Note the following torque settings:



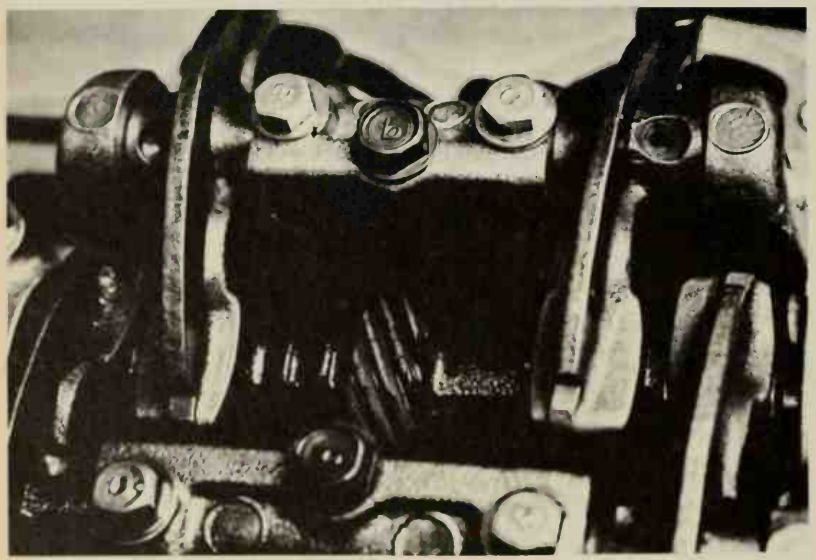
8 mm: 14–17 ft. lbs.
10 mm: 25–33 ft. lbs.

TOP END



Cylinder Head Removal (1969–78)

1. Remove the engine from the frame. This is not necessary on 750A models provided that the gas tank, carburetors, and exhaust system are removed. Remove the spark plugs.
2. Take out the three bolts and remove the breather cover. Remove the starter motor cover.
3. Remove the cam cover screws and take off the cover, tapping the sides carefully with a plastic mallet to break it free, if necessary.
4. Remove the keeper bolts from each rocker arm shaft after the engine has been turned so that the two valves for the shaft you are removing are *closed*. After the bolts are removed, the shaft should be able to be pushed out easily. If this is not possible, turn the engine over slowly until the shafts are free.



NOTE: *Rocker arms and rocker arm shafts should be marked for location so that they*

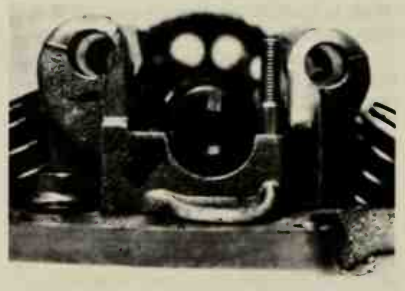
Valve cover screws

Top end components

Rocker arm shaft bolts

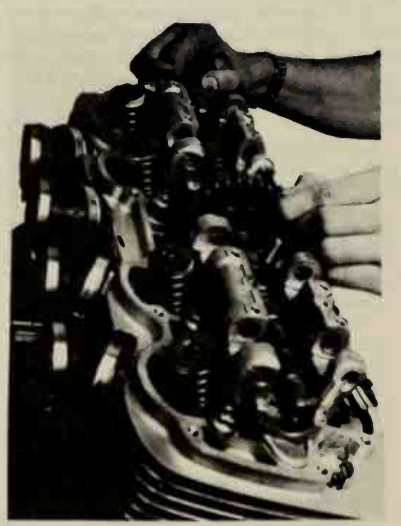
can be reinstalled in their original locations.

5. Turn the engine over to align the valve timing marks at the right end of the camshaft with the cam bearing cap joint, as illustrated. Unbolt and remove the cam bearing caps.



Note that each cap is coded with a mark stamped on the cap and the cam holder which indicates the proper location of each cap, and the proper direction it is to be installed. Caps must be installed in their original locations and in the proper direction since they are line-reamed at the factory after being bolted together in this way.

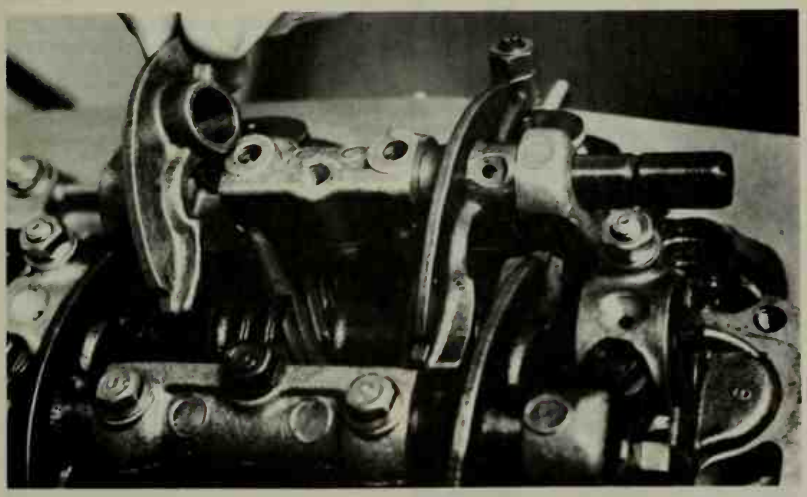
6. Remove the two cam sprocket bolts. Remove the cam chain tensioner from the cylinder.



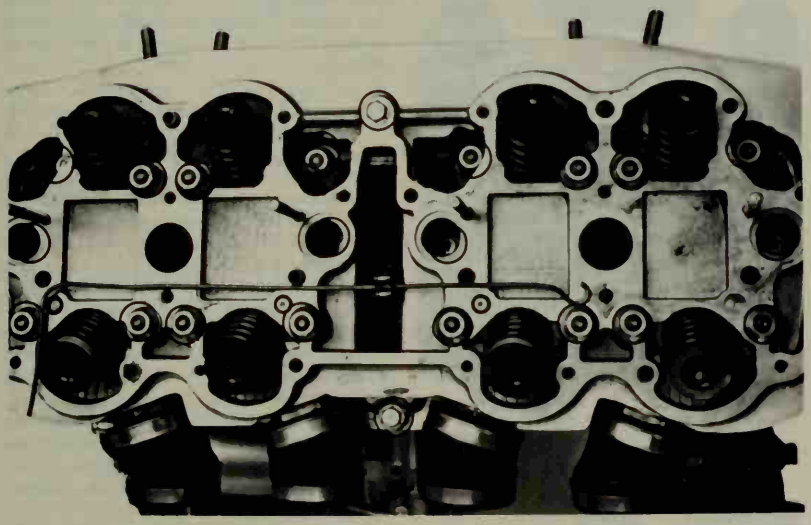
7. Disengage the cam sprocket from the camshaft and the chain from the sprocket. Carefully remove the camshaft, turning it this way and that so that the lobes clear the sprocket.

NOTE: *Wire the chain out of the way. Do not allow excess slack in the chain or it may slip off its sprocket on the crankshaft. If this happens, it will be necessary to split the cases to retrack the chain.*

8. Remove the cam holders.

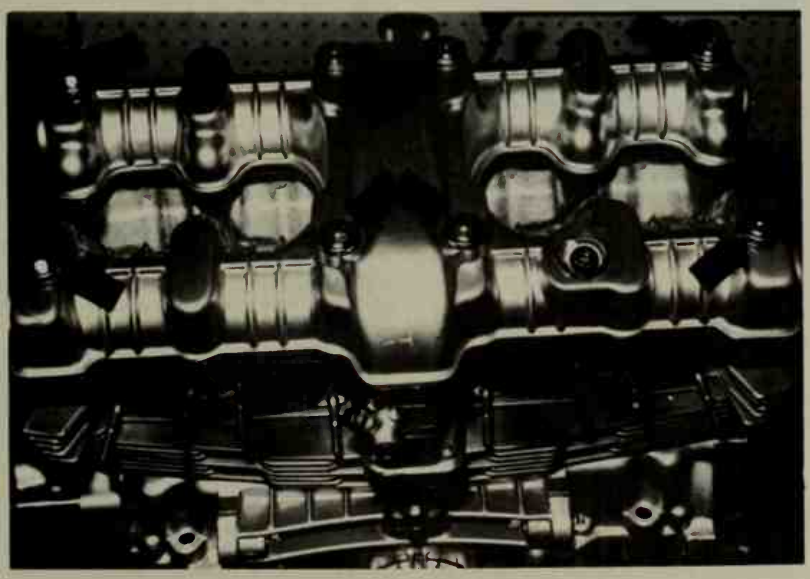


Align the cam timing marks before unbolting the cam caps



Removing the camshaft

9. Remove the four rubber caps which cover cylinder head bolts. Remove these bolts and the set bolts at the rear and front of the head.



10. Gradually loosen the 16 main cylinder head nuts, starting with the outermost nuts

Removing a rocker arm

Cylinder head nuts

Cam cover bolts

first. Lift off the cylinder head. Be sure to secure the cam chain so it doesn't fall into the cylinder.

Cylinder Head Removal (1979–81)

NOTE: *The camshafts may be removed and replaced with the engine still in the frame. Removal of the cylinder head, however, requires engine removal. If removal of the cams only is required, follow the procedure starting at Step 2.*

1. Remove the engine from the frame.
2. Remove the cylinder head cover bolts and the cylinder head cover.
3. Remove the oil line alongside the cam chain guide. Remove the chain guide as well.
4. The camshaft holders are marked "A" to "E" on the exhaust side and "F" to "L" on the intake side. Note the marks. Proper installation is critical. When installing, the arrow marks must face forward.
5. Remove the camshaft holders "B," "C," "H," and "J."
6. Remove the oil reservoir caps and the *rear* cam chain guide attaching plate.
7. Remove the dowel pins.
8. Loosen the front cam chain tensioner locknut and bolt. Press the cam chain tensioner down, then retighten the lockbolt and nut. This will get a lot of the tension out of the chain.
9. Loosen the rear chain tensioner adjusting locknut. Pull the rear cam chain tensioner up to reduce chain tension and tighten the adjusting locknut.
10. Remove the pulser generator cover. Turn the crankshaft counterclockwise until the "1.4T" mark on the rotor aligns with the index mark.
11. Make sure that the intake *and* exhaust cam lobes for cylinder No. 1 or No. 4 both face the spark plug. If not, turn the engine 360° so that this condition is met.
12. Remove camshaft holders "G" and "K." Remove holders "F" and "L." Remove the dowel pins.
13. Remove the intake camshaft.
14. Remove the accessible exhaust cam sprocket bolt. Turn the crankshaft counterclockwise until the other cam sprocket bolt can be removed. Remove the "D" and gear camshaft holders. Remove holders "A" and "E."
15. Remove the exhaust cam. Remove the dowel pins.
16. Loop a piece of wire around the cam chain to keep it from falling into the crankcase. Remove the cam sprocket.
17. Valve adjusting shims and lifters can now be removed. Be sure to mark all components for position before removal.
18. Remove the oil line at the rear of the cylinders.
19. Remove the two rear cam chain tensioner locknuts.
20. Remove the two cam chain housing bolts.
21. Remove the 12 cylinder head cap nuts.

NOTE: *Loosen the bolts gradually and in a cross pattern to prevent head warpage.*

22. Remove the cylinder head. Remove the head gasket, dowel pins at the sides, and the cam chain guide. Be sure to secure the

Top end oil line

cam chain so that it doesn't fall into the cylinder.

Cylinder and Piston Removal (All Models)

1. 1979–81: Remove the bolt from the lower front cylinder base.

2. Carefully lift the cylinder unit away from the crankcase. If it can't be raised easily, tap the sides *lightly* with a rubber mallet to break the seal.

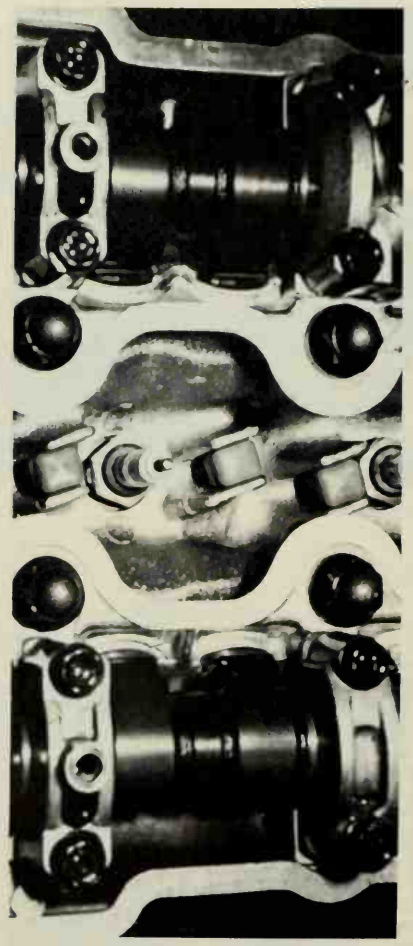
3. 1979–81: Remove the cam chain tensioner. 1969–78: remove the two cam chain tensioner rubber mounts from the crankcase and lift out the tensioner roller assembly. The guide roller can be removed from the tensioner by pushing the roller pin.

4. 1969–78: remove the cam chain guide pin from the bottom of the cylinder and withdraw the guide assembly.

5. All: remove the wrist pin circlips from the pistons.

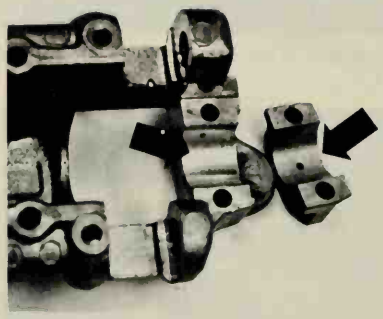
CAUTION: *Do not allow the circlips to fall into the crankcase. To avoid having to split the cases to retrieve a clip, cover the crankcase openings with a cloth.*

Discard the circlips once they have been removed. New circlips must be used on assembly.



6. Remove the wrist pins from the pistons and mark the pistons, inside the skirt, so they can be replaced in their original bores.

The wrist pin should be pushed out while supporting the piston with one hand. Never strike or attempt to drift out a wrist pin, or the connecting rod may be bent. If the wrist pins resist removal, heat the piston crown(s) gently with a propane torch or the like until the pins can be pushed out easily.



Inspection

CAMSHAFT

1. On 1969–1978 models, to check camshaft bearings wear, install the camshaft holder on the cylinder head and install the bearing caps on the holder. Check the marks on the holder and caps to ensure that the caps are installed in their original positions. Torque the capnuts and bolts to 8 ft. lbs. Measure the inside diameter of one of the

Make sure that the intake and exhaust lobes for cylinder No. 1 or 4 face the spark plug

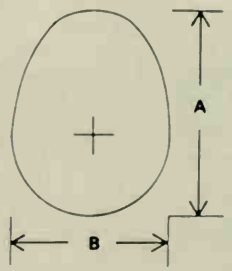
Check the cam bearing for signs of scoring or wear

Measuring the camshaft journal diameter

bearings with an inside micrometer in both the horizontal and vertical directions and then calculate the average value. Next, measure the diameter of the corresponding, camshaft journal and compute the bearing clearance. Repeat this operation for the remaining camshaft bearings. Replace the holder and caps as a set if clearance of any bearing exceeds 0.21 mm (0.0083 in.).

NOTE: *Bearing clearance may also be measured using a material such as plastigauge.*

2. On 1979–1981 models, the cam bearing clearance should be checked with plastigauge.



Remove the adjusting shims and valve lifters. Be sure to mark each part for reassembly. Remove any oil residue from the journals. Put a strip of plastigauge on each journal, then install the holders. Be sure that each holder is fitted on the proper journal, and that the arrow faces the front of the engine. Holders are marked "A" to "E" for the exhaust and "F" to "L" for the intake cams respectively, from left to right side of the engine. Tighten the holders in a cross pattern to 9–12 ft. lbs. Service limits are as follows:

A, E, F, L:	0.13 mm (0.0051 in.)
D, G, K, gear:	0.16 mm (0.0063 in.)
B, C, H, J:	0.19 mm (0.0075 in.)

If the clearance of any of the journals exceeds specifications, replace the camshaft and recheck. If clearance is still too high, the head must be replaced.

NOTE: *Holders and head are replaced at the same time.*

3. Examine the camshaft lobes for scoring and wear. If the lobes are visibly imperfect, the camshaft should be replaced. The lobes should present a bright, shiny, and unmarked surface. Measure the cam height as illustrated ("A" in the illustration). Minimum acceptable measurements are given in the specification chart at the end of this section.

Cam lobe height (A) and base circle diameter (B)

On 1969–1978 models, the base circle diameter of each cam lobe should be not less than 27.93 mm (1.099 in.). The base circle measurement ("B" in the illustration) is taken in a plane perpendicular to the cam height measurement, through the camshaft centerline. Replace the camshaft if the base circle measurements are not within specification.

4. Check camshaft run-out using a dial indicator while rotating the camshaft. To obtain an accurate reading, the ends of the camshaft should be supported in machined V-blocks. Camshaft run-out must not exceed 0.1 mm (0.004 in.), true indicated reading.

ROCKER ARMS AND SHAFTS (1969-1978)

1. Measure the inside diameter of the rocker arm supports and measure the diameter of the rocker arm shaft in the area of bearing contact. If calculated clearance exceeds 0.11 mm (0.0044 in.), replace parts as necessary to reduce clearance to within the limit. Check the fit of the rocker arms on the shafts and replace the arms and/or shafts if play is excessive.

2. Check the condition of the rocker arm bores and the corresponding areas of the shafts. Note any blue discoloration which might be due to excessive heat or lack of lubrication. Replace the rocker arms and shafts if this condition exists, or if there are obvious signs of damage, such as scoring.

CYLINDER HEAD

1. Clean any traces of head gasket material from the cylinder head mating surface. Place a straight edge across the mating surface and check for warpage by attempting to slip feeler gauge blades between the head and straight edge. Standard head warpage is about 0.05 mm (0.002 in.), and maximum allowable warpage is 0.1 mm (0.004 in.). At this point, the head should be milled to restore a flat mating surface.

2. Use a wire brush fitting on a power drill to decarbonize the combustion chambers. The valves should be left in place as this is done, as it minimizes the chance of causing damage to the valve seats.

VALVE ASSEMBLY

1. To remove the valves, and install them properly, a suitable C-clamp is necessary. Compress the valve springs and remove the split collars, retainers, springs, seals, and spring seats. Inspect the valves, guides, springs, and valve seats in the following manner. Keep each assembly separate so that every piece can be installed in its original location. New valve seals must always be used on assembly.

2. If considerable mileage has been covered, the valve springs should be replaced as a matter of course. Always replace the valve springs as a complete set.

Check valve spring free-length with a micrometer. Replace the springs if any is below the following service limits.

1969-1978 (inner): 37.0 mm (1.457 in.)
(outer): 40.0 mm (1.575 in.)
1979-81 (inner): 39.8 mm (1.57 in.)
(outer): 42.5 mm (1.67 in.)

3. Each valve must be free to move up and down in its guide with little resistance. Any sticking or binding as the valve is moved in the guide will indicate that the valve stem or guide is in poor condition.

4. Inspect the valve, paying close attention to the edges of the valve head for pitting, burnt or broken edges, excessive carbon buid-up, etc. A certain amount of carbon and lead deposits on the valve face and the top of the exhaust valve are inevitable. Heavy deposits should be carefully scraped off with a dull knife, or a wire wheel, and the valve finished up with very fine emery cloth.

Do not touch the valve seating area during these operations.

If the valve has burnt or broken edges, it must be replaced.

5. On 1969-1978, models, check the end of the valve stem for indented wear caused by the valve adjuster. Although rare, it may occur after long mileage. Since an indentation here will make proper valve adjustments impossible, the valve should be replaced.

NOTE: *The tips and edges of the valves are stellite-coated. Machining for any reason is not recommended. In case of wear, replace the valve.*

6. Carbon deposits should not extend too far up along the valve stem. This would indicate a worn or cracked valve guide.

7. Wet, oily deposits on the back of the valve head is indicative of a worn guide or bad seal. Less severe wear to these components show up as brown oil stains on the valve stem.

8. Holding a valve in your fingers, spin it while observing the head. A wobble is indicative of a bent valve. If a dial gauge is available, check the run-out of the head. Replace the valve if run-out exceeds 0.05 mm (0.002 in.). Run-out is the total indicated dial gauge reading.

Attempt to rotate the valve by hand when it is fully inserted into the guide. If the valve will not rotate easily, or if it sticks as it is turned, it is probably bent.

9. Check valve-to-stem clearance and compare to the specification given. There are two ways of doing this. The first is to measure the diameter of the valve stem and the diameter of the inside of the guide and subtract the difference. Another way, somewhat easier, is to insert the valve into the guide, holding it about ½ in. off the seat, and check the total amount of allowable movement in two directions using a dial gauge.

NOTE: *Ream the valve guides to remove any carbon deposits before checking clearance. Maximum allowable clearances are as follows:*

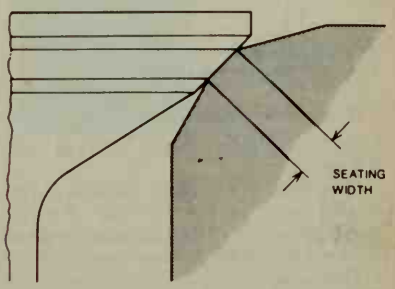
1969-1978 (intake): 0.08 mm (0.003 in.)
(exhaust): 0.1 mm (0.004 in.)
1979-1981 (intake): 0.07 mm (0.003 in.)
(exhaust): 0.09 mm (0.004 in.)

10. On 1979-1981 models, valve stem diameter should be measured at three places along the length of the valve. Serviceable limits are 5.47 mm (0.215 in.) for the intake valves, and 5.44 mm (0.214 in.) for the exhaust valves. Serviceable limits for the guides are 5.54 mm (0.218 in) for the intake guides, and for the exhaust guides.

11. If the valve-to-guide clearance is too high, the guides are probably the component which needs replacement. If replacement of the guides does not bring the clearance to within specification, replace the valves as well.

NOTE: *After installing new guides, the valve seat should be recut and the valves lapped in.*

A quick check of the operational worthiness of a valve and guide can be accomplished by dipping the valve stem in oil and inserting it into its guide. Place a finger over the other end of the guide. Pull the valve a little way out of the guide and release it. The valve should be drawn back into the guide by suction if the components are in serviceable condition.



12. To remove valve guides, use a suitable drift, or Honda tool No. 07046-30001. Heating the head in an oven will facilitate removal and installation. Be sure the set rings are in place on the guides before installation. Be sure the guides are fully seated.

After installing a new guide, it must be reamed to the proper size. On 1969-1978 models, this should be 6.60-6.61 mm (0.2598-0.2602 in.). On 1979-1981 models, the proper inside diameter is 5.50-5.52 mm (0.2165-5.52 mm (0.2165-0.2171 in.).

13. Check the width of the valve seat and the valve seating area. Valve seat width should be 1.0-1.3 mm (0.039-0.051 in.). The seat should be recut if the width exceeds 1.5 mm (0.06 in.).

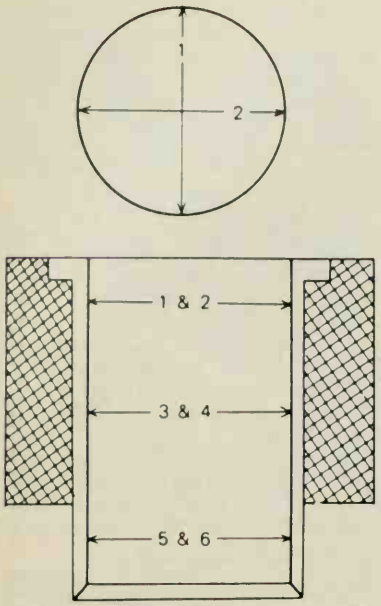
14. Check the sides of the valve lifters, and replace any which show scoring or unusual signs of wear. Measure the diameter of each lifter if a micrometer is available. Replace any which measures less than 27.96 mm (1.101 in.).

15. Measure the inside diameter of the valve lifter bores. If the bores measure more than 28.04 mm (1.104 in.) in diameter, the head should be replaced.

Valve seat width measurement point

Springs are installed with the close coils (arrows) towards the head

NOTE: *Valve springs are progressively wound. When installing them, be sure they are fitted with the close coils towards the cylinder head. Some models have the tops of the springs painted white.*



CYLINDERS AND PISTONS

1. Make a visual inspection of the cylinder bore, noting any imperfections. The cylinder walls should be uniformly smooth.

2. With an inside micrometer, measure the diameter of each bore at the top, middle, and bottom. Make measurements in two directions, 90° apart, both parallel and perpendicular to the piston wrist pins.

Maximum allowable cylinder bore diameters are as follows (standard bore):

750, 1969-1978: 61.1 mm (2.406 in.)
750, 1979-1981: 62.1 mm (2.445 in.)
900, 1980-1981: 64.60 mm (2.543 in.)

Cylinder measurement points

If any of the measurements exceeds this figure, the cylinders should be bored to the first oversize.

If the difference between the high and low measurements in any direction is greater than 0.05 mm (0.002 in.), the cylinder should be bored out to the next oversize.

Maximum allowable bore diameter difference between cylinders is 0.1 mm (0.004 in.)

3. Make a visual inspection of the pistons. Scoring, scuffing, or seizure marks on the piston shirts may be removed with a fine grade of emery or crocus cloth if they are not too severe. Sanding should be done in a cross-hatch pattern. If the damage is severe (more than about ½ in. wide), the pistons should be replaced.

4. The rings must be free to move in the piston grooves. If they cannot, either they are carbon clogged (which necessitates replacing the rings and cleaning out the grooves), or metal has been pushed into the grooves by a piston seizure. In this event, pistons and rings must be replaced. Carbon-clogged rings are almost always broken when an attempt is made to remove or free them, so be prepared to buy a new set.

5. Measure the diameter of the pistons about 10 mm (0.4 in.) from the bottom of the skirt perpendicular to the wrist pin. Replacement limits for standard size pistons are as follows:

750, 1969-1978: 60.85 mm (2.3957 in.)
750, 1979-1981: 61.90 mm (2.4370 in.)
900, 1980-1981: 64.40 mm (2.535 in.)

NOTE: *New pistons come with the wrist pin and rings. If oversized pistons are needed due to a worn bore or worn or damaged piston, obtain the pistons first, then have your dealer or a machine shop bore the cylinders to the proper size. This is obtained by measuring the diameter of the new pistons and boring the cylinder to that size plus the piston-to-cylinder clearance of 0.025-0.050 mm (0.001-0.002 in.).*

There are four piston oversizes available in increments of 0.25 mm. The size is stamped on the piston crown.

6. If an inside micrometer is available, measure the inside diameter of the wrist pin holes. The wrist pins should be a light push fit into the holes. If too loose, the pistons should be replaced.

Maximum allowable wrist pin hole diameter is as follows:

750, 1969-1978: 15.08 mm (0.5937 in.)
750, 1979-1981: 15.05 mm (0.5930 in.)
900, 1980-1981: 15.05 mm (0.5930 in.)

7. Check the condition of the wrist pins. Measure the diameter of the pins at three places along their length and compare the diameter to the service specification. The minimum allowable wrist pin diameter is as follows:

750, 1969-1978: 14.96 mm (0.589 in.)
750, 1979-1981: 14.98 mm (0.590 in.)
900, 1980-1981: 14.98 mm (0.590 in.)

Replace the wrist pins if any of the measurements is under this limit, or if they are discolored from overheating.

8. The wrist pins ride directly on the connecting rod small ends. Measure the inside diameters of the small ends and compare to the service limits:

All models: 15.07 mm (0.5933 in.)

If the meaurements are larger than these limits, the rod(s) must be replaced.

9. Although not as conclusive as a direct measurement, the condition of the wrist pins and small ends can be checked by inserting the pins and checking for vertical movement. There should be none. If there is noticeable movement in the pins, either the pins or the rods, or both, are in need of replacement. If the rod small ends are discolored or scored, the rods should be replaced.

10. Check the connecting rods for a bent condition. This can be accomplished with two small rectangular blocks of metal of equal thickness. Insert the wrist pins into the rods, and position the pieces of metal beneath them on either side of the rods and resting on the crankcase. Rotate the engine so that the wrist pin rests on the blocks. Both sides of the wrist pin must contact the metal blocks, or the rod is bent and must be replaced.

11. Before installation, decarbonize the piston crowns. Remove any carbon from the ring grooves with a piece of broken ring or a very thin screwdriver. Be careful not to scratch the grooves.

Carefully check the cylinder, cleaning the bores thoroughly. If considerable mileage has been covered, honing the cylinders and fitting new rings is recommended. If the cylinders are honed, make a strenuous effort to clean them thoroughly afterwards, preferably with very hot soapy water and a stiff brush. This is to remove any abrasive particles deposited by the hone in the course of the operation.

Remove any traces of gasket material from the cylinder base and the head mating surface.

12. Be sure that all oil passages in the cylinder are clear. Check the condition of the cam chain tensioner guides and replace them if damaged.

13. Replace the cylinder base o-rings. Check that any o-rings and the important dowel pins fitted to the cylinders are in their proper locations before installation.

PISTON RINGS

Two checks to be made on the piston rings are side clearance and end-gap. These checks should be made on both new and used rings.

1. Piston ring side clearance for compression rings and one-piece oil rings is checked with the rings installed on the piston. Insert a feeler guage blade between the ring and the ring groove and check that the clearance is within the specification given for your machine in the "Engine Specifications" chart at the end of this section. If the clearance is too large, the rings or grooves are worn. If too small, metal may have been pushed into the grooves due to a piston seizure. Check that the grooves are not just carboned up. If new rings do not bring the clearance to the proper value, the pistons must be replaced.

2. To remove the rings from the piston, use a ring spreader as illustrated. They are available at most auto stores. Decarbonize the ring grooves.

3. To check the ring end-gap, ensure first that the cylinder bore is not excessively worn. Place each ring, in turn, into the bottom of its cylinder and push it in an inch or more using the piston skirt to align the ring in the bore. Measure the end-gap with a feeler gauge. If the end-gap is larger than the service limit, the rings must be replaced. If the measured end-gap of new rings is too large, the cylinder is worn and should be bored to the next oversize.

If new rings are fitted and the end-gap is too small, the ring ends must be filed. Hold the ring steady as illustrated, closing the ends over a thin, fine file. Do not squeeze the ring, as this is the easiest way to break it. A few strokes of the file will increase the end-gap.

Removing rings with a ring expander

Filing ring ends

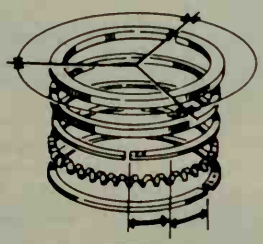
CAUTION: *Do not make more than a few strokes before checking the end-gap again. It is easy to remove too much metal.*

Do not allow the file to slip out of the ring, as this risks breaking it.

4. Roll each ring around its own groove and ensure that this can be done easily. If a ring sticks or binds in the groove, the pistons must be replaced.

Cylinder and Piston Installation (All Models)

1. When installing piston rings, note that all rings are installed with the manufacturer's mark (the small letter near the end-gap) facing *up*.



NOTE: *The compression rings are not interchangeable. The upper compression ring has beveled edges and is chrome-plated, while the lower one has a square or angled cross-section.*

2. To install the three-piece oil ring, install one rail on the piston below the oil ring groove, fit the expander, then move the rail into place. Install the top rail.

Always install rings so that the letter near the end-gap faces up

Ring end-gap positions with three piece oil ring

3. Use a ring expander to install the rings to reduce the chance of breaking them.

4. Ring end-gaps must be staggered around the piston so that they do not overlap. If a one-piece oil ring is used, space the end-gaps about 120° apart, but do not position any of them at the very front or very rear of the piston, or directly over the wrist pin hole.

The same thing holds true of models with the three-piece oil ring, except that the rail end-gaps should be positioned to either side of the expander as illustrated.

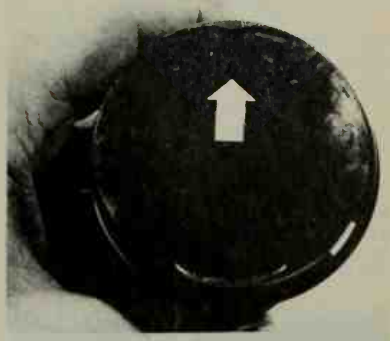
5. Install the pistons on their connecting rods so that the arrow marks on the crown face the front (exhaust side) of the engine on 1969–1978 models. On 1979–1981 models, install the pistons so that the "IN" marks are towards the rear.

NOTE: *Be sure to use new wrist pin circlips.*

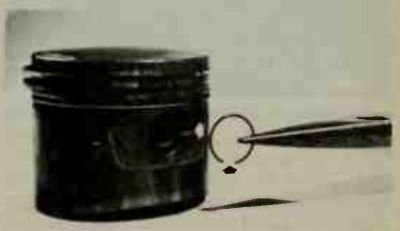
6. Slip the wrist pins into place, heating the piston crown as on removal if necessary. Install the wrist pin circlips with a needle-nosed pliers. Be sure each circlips is firmly seated in its groove and arranged so that the circlip end-gap and the cut-out in the piston do *not* align.

7. Lubricate the rings and piston skirts with clean motor oil.

8. Install o-rings and dowel pins on the crankcase mating surface. On 1969–1978 models, the o-rings go to the rear centermost studs, while the dowel pins are located on the front outside studs. Location is critical. Install the cylinder base gasket. On 1979–1981 models, the dowel pins go behind cylinders Nos. 1 and 4.



To install three-piece oil rings, fit the first rail below the ring groove, install the expander, then the top rail



Stagger oil ring end-gaps (arrows)

9. Route the cam chain through the chain tensioner roller, mount the roller assembly on the upper crankcase, and install the rubber mounts. Make sure that the chain guide is positioned correctly in the cylinder.

10. Rotate the engine until No. 2 and 3 pistons are at top dead center, and place a piston base under the pistons to hold them in position. (A block of wood cut to suitable size works just as well.) Compress the rings on

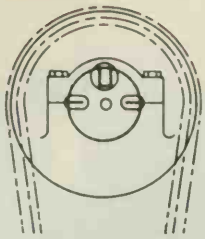
Install the pistons so that the arrows face the front of the engine

When fitting the wrist pin circlips, the piston cut-out and circlip end-gaps should not align

No. 2 and 3 pistons and slide the cylinder barrel down over them. Rotate the engine until No. 1 and 4 pistons contact the base of the cylinder (taking care not to pull No. 2 and 3 pistons out of their bores). Compress the rings and slide the cylinder over the pistons. Before seating the cylinder against the crankcase, raise the cam chain through the center of the cylinder and put a screwdriver through the center of it to keep it from dropping down, or attach a piece of mechanic's wire to the chain and pull it up.

Cylinder Head Installation (1969–78)

1. Install the o-rings and dowel pins on the cylinder. The o-rings are located at the rear centermost studs while the dowel pins go to the front outside ones.



NOTE: *On 1974 and later models, each set of four studs between cylinders 1 and 2 and between 3 and 4 are fitted with a collar and oil seal between the cylinder and cylinder head.*

Install the head gasket.

2. Mount the cylinder head on the cylinder while pulling the cam chain through the center of the head. Hold the chain to keep it from dropping into the crankcase, using a screwdriver or a length of wire.

3. Install the cylinder head fasteners and tighten them gradually and evenly in the sequence shown. Tighten the 6-mm bolts to 8 ft. lbs. and the 8-mm nuts to 15–18 ft. lbs. This tightening is done in a cross pattern starting at the middle of the head and working outwards.

NOTE: *Cylinder studs should be clean and dry for an accurate torque reading.*

When the "T" mark for cylinder 1 & 4 are aligned with the index mark, install the cam with the cut-out at the top and the two slash marks aligned with the cam cap mating surface as shown

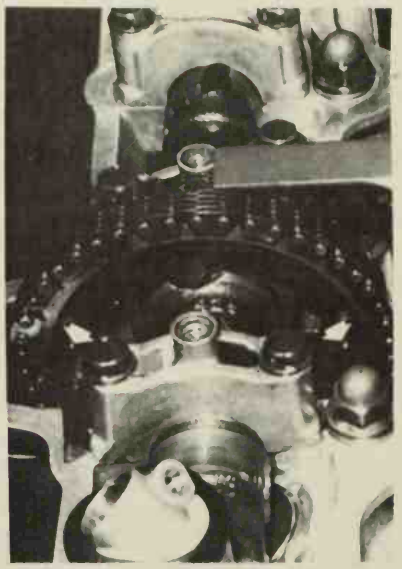
Install the cam bearing caps so that the marks (arrows) match up

4. To set the valve timing properly, remove the ignition points cover and rotate the engine clockwise until the "T" mark (for No. 1 and 4 pistons) aligns with the index timing mark (top dead center). Install the camshaft holders onto the head, hold the cam chain and sprocket together, and install the camshaft. Rotate the camshaft until the marks at the end of the shaft are aligned with the bearing cap joint, as illustrated. The groove must be toward the top. Place the cam chain over the sprocket, bolt the sprocket onto the camshaft, tighten the sprocket bolts to 12–15 ft. lbs., and install the bearing caps. Make sure that the caps are replaced in their original positions (note the matching marks on cap and holder), and tighten the cap nuts and bolts to 7–9 ft. lbs.

5. Install the rocker arms and rocker arm shafts, tightening the shaft retaining bolts to 6–9 ft. lbs. Make sure that the rocker arms are installed in their original positions. Loosen the cam chain tensioner locknut and adjuster bolt, and install the tensioner on the rear of the cylinder.

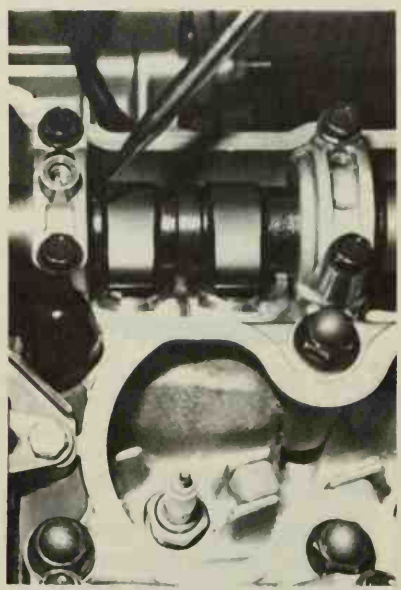
Lubricate all top-end components with clear engine oil.

6. Adjust the valve clearance in accordance with procedures described in chapter 3, and install the camshaft cover.



NOTE: *Before the cover is installed, take out the tachometer drive-gear limit bolt, coat the threads with threadlock compound, and tighten the bolt firmly to prevent the possibility of it loosening from heat and vibration.*

7. Fit the breather cover and install the engine in the frame. Perform a complete tune-up. Do not neglect to adjust the cam chain tension and refill the engine with oil.



Cylinder Head Installation (1979–81)

1. Tighten the two cam chain tensioner locknuts at the rear of the cylinder block.

2. Loosen the lower adjusting locknut and pull the tensioner up. Retighten the locknut.

Exhaust cam punch marks aligned with cylinder head mating surface (arrows)

Cam caps must be installed so that the arrows on them point towards the front of the engine

3. Install the dowel pins, head gasket, and cam chain guide.

4. Install the cylinder head assembly.

5. Tighten the cap nuts gradually and in a cross pattern starting in the center and working outwards. Tighten the nuts a few ft. lbs. at a time until the proper torque of 26–29 ft. lbs. is reached.

NOTE: *Cylinder studs should be clean and dry for an accurate torque reading.*

6. Lubricate the cam chain housing bolts with molybdenum disulphide or the like and install them.

7. Install the oil line. The banjo bolt with the larger oil orifice hole on the side is installed at the *top*.

8. Lubricate the camshaft bearings with an assembly lube.

9. Turn the crankshaft counterclockwise until the "1.4 T" mark aligns with the index mark.

10. Pull the cam chain tensioner up as far as possible.

11. Place the intake cam chain over the exhaust cam sprocket, aligning the sprocket punch marks with the cylinder head mating surface.

12. Insert the exhaust camshaft through the sprocket and the exhaust cam chain, positioning the cam lobes for the No. 1 (left) cylinder towards the spark plug.

13. Engage the exhaust cam chain with the sprocket. Install cam holders "A" and "E" loosely. Fit one of the cam sprocket bolts.

NOTE: *The arrow marks on the cam holders point towards the front of the engine.*

14. Install the cam holder "D" and the tach gear holder. Be sure to position the cam so that the flange fits into holder "D".

15. Turn the crankshaft counterclockwise 360° and install the other camshaft sprocket bolt. Tighten the bolt to 13–15 ft. lbs. Turn the crankshaft around again and tighten the first sprocket bolt to 13–15 ft. lbs.

16. Tighten the cam holder bolts in a cross pattern to 9–12 ft. lbs.

17. Adjust the front cam chain with the locknuts on the rear of the cylinder.

18. Make sure that the "1.4T" mark on the crankshaft aligns with the index mark. Make sure that the cam lobes for cylinder No. 1 face the spark plug. Check that punch marks on the exhaust cam sprocket are aligned with the cylinder head mating surface.

When these conditions are met, engage the intake cam chain with the intake cam sprocket aligning the sprocket punch marks with the cylinder head in the same manner as for the other sprocket.

19. Install the intake cam, positioning the cam lobes for the No. 1 cylinder towards the spark plugs. Install, but do not fully tighten, a cam sprocket bolt.

NOTE: *If the sprocket was not removed from the camshaft, install the assembly together.*

20. Loosely install cam holders "F" and "L." Install "G" and "K." Be sure to position the cam so that its flange fits into the slot in the "K" holder.

21. Tighten the cam sprocket bolts to 13–15 ft. lbs. as was done with the other two.

22. Tighten the cam holder bolts gradually and in a cross pattern to 9–12 ft. lbs.

23. Adjust the intake cam chain tension with the locknut at the front of the engine.

24. Recheck valve timing mark alignments before attempting to turn the engine over.

25. Install the exhaust cam chain guide attaching plate and oil reservoir caps.

26. Install the oil line and cam chain guide with the "B," "C," "H," and "J" holders.

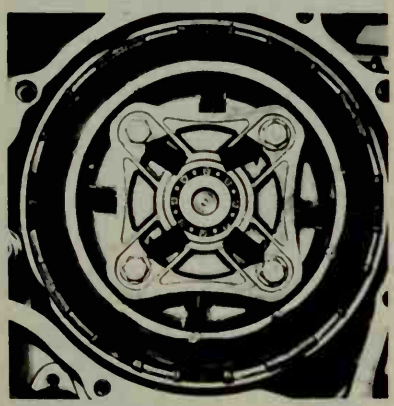
27. Lubricate the cam lobes and bearings with motor oil. Adjust the valves.

28. Apply a liquid sealant to the cylinder head cover gasket, and install the cover. Tighten the bolts to 6–9 ft. lbs.

29. The remainder of the procedure is the reverse of disassembly.

CRANKCASE COVER COMPONENTS MANUAL TRANSMISSION MODELS

The following sections deal with the removal, inspection, and installation of those components found beneath the left and right crank-



case covers. These include the clutch, breaker points, alternator, starter drive, and shift mechanism. These components can be serviced with the engine in the frame.

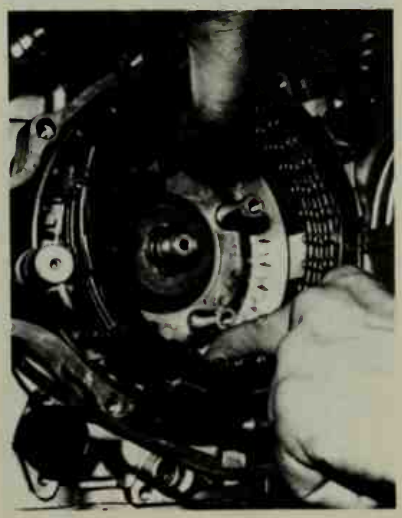
Clutch (1969–78)

REMOVAL

1. Drain the oil from the crankcase. Place a drip pan beneath the clutch cover to catch any residue remaining in the clutch case when the cover is removed.
2. Remove the kick-start lever.
3. Remove the clutch cover plate. Disconnect the cable from the release lever. Detach the cable from the clutch cover.
4. Remove the clutch case cover screws and take off the cover. If it is stuck, tap lightly on the top and sides to break it free. Pull the cover off carefully, taking care that the kickstart shaft oil seal does not contact the shaft splines any more than is necessary.
5. Unscrew the four clutch lifter plate bolts, threading them out gradually and evenly. Remove the bolts, plate, and springs.
6. Unscrew the clutch hub nut. A Honda special tool is available for this job (No. 07916-2830000), but a socket of about the right size can be modified to fit the clutch hub nut if you are handy.

Remove the tongued washer and lockwasher. Remove the clutch hub.

Clutch spring bolts



Clutch hub nut removal requires a special socket

7. Remove the outermost friction plate and stopper ring. Remove the friction plates and steel plates.
8. Remove the clutch washer, pressure plate, and clutch housing.

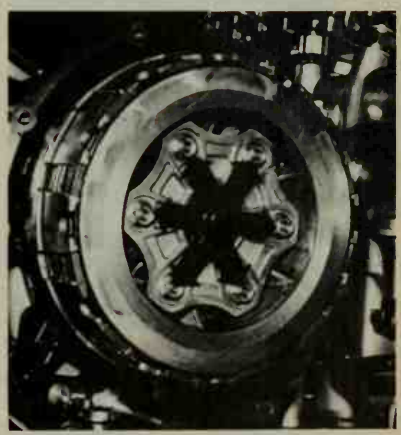
INSPECTION

1. Check the condition of the kick-start shaft oil seal. If it leaks, or if the lips show signs of damage, pry the old seal out with a small screwdriver. Press the new seal straight into the cover. Apply some oil or grease to the seal lips before installation.

Removing the clutch plates

2. Check the condition of the clutch cover mating surface. Remove any burrs or imperfections with an oilstone.
3. Measure the thickness of the friction plates, and replace them if they are less than 3.1 mm (0.122 in.) thick.
4. Place the steel clutch plates on a flat surface, such as a piece of glass, and check for excessive warpage by attempting to slip a feeler gauge blade between the surface and the plate. Replace the steel and friction plates as a set if warpage exceeds 0.3 mm (0.012 in.).
5. Measure the free-length of each clutch spring and replace them as a set if any are found to be less than 30.5 mm (1.2 in.) long, or if their length varies. If the latter is true, be sure that all of the bolts are evenly tightened on assembly.
6. Check the friction plate tabs for wear or damage. Check the clutch housing for indented wear caused by the tabs. Remove any burrs with a file or oilstone.
7. Check the corresponding splines of the clutch hub and steel plates for indented wear.
8. Check the condition of the lifter plate bearing. Rotation must be smooth, noiseless, and effortless. Replace the bearing if rotation is rough, the races loose, or rotation noisy.

ASSEMBLY

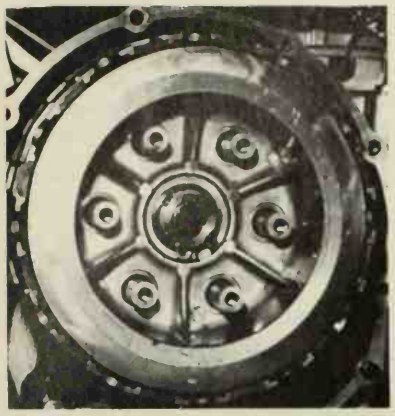


1. Install the clutch housing and spline washer on the mainshaft.
2. Install the pressure plate and install the friction and steel plates alternately, beginning with a friction plate, until all are in place. Install the stopper ring, then the outer (smaller diameter) friction plate.
3. Install the clutch hub, spring washer, lockwasher, and nut. Tighten the hub nut to 33–36 ft. lbs.
4. Install the clutch springs and lifter plate assembly, tightening the spring bolts gradually and evenly. The remainder of the procedure is the reverse of removal.
5. Adjust the clutch and the clutch cable after assembly is completed.

Clutch (1979–81)

REMOVAL

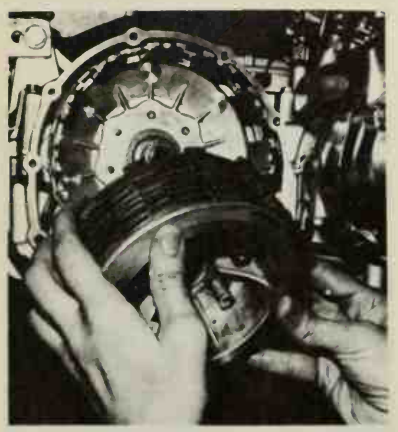
NOTE: *Removal of the clutch hub nut requires a special tool.*



1. Drain the oil from the crankcases.
2. Run the clutch cable adjuster at the handlebar in all the way, and then disconnect the cable from the lever at the engine.
3. Remove the rear brake pedal pinch bolt and carefully pull the pedal from its splined shaft.
4. Remove the clutch cover. Place a drip pan beneath the cover before removal to catch any oil remaining in the clutch case. Remove the clutch cover gasket and dowel pins.
5. Remove the clutch lifter shaft and adjusting arm, if desired.
6. Gradually, and in a cross pattern, loosen the six clutch spring bolts and remove the lifter plate and springs.
7. Temporarily refit the brake pedal.

Clutch spring bolts

Removing the pressure plate



A special socket is required to remove the clutch hub nut

Place the transmission gear, apply the rear brake, and remove the clutch hub nut with the special tool after bending down the tab on the lockwasher.

8. Remove the clutch assembly. There is a shim on the clutch shaft behind the assembly.

9. Remove the clutch hub. Remove the clutch steel plates and friction plates.

Removing the clutch plates

NOTE: *Keep the plates in order. They are not interchangeable. Note the locations of the washer and collar.*

INSPECTION

1. Check the condition of the clutch cover mating surface. Remove any burrs or imperfections with an oilstone.

2. Measure the thickness of the friction plates, and replace them if they are less than 3.4 mm (0.13 in.) thick.

3. Place the steel clutch plates on a flat surface, such as a piece of glass, and check for excessive warpage by attempting to slip a feeler gauge blade between the surface and the plate. Replace the steel and friction plates as a set if warpage exceeds 0.3 mm (0.012 in.).

4. Measure the free-length of each clutch spring and replace them as a set if any are found to be less than 32.8 mm (1.3 in.) long, or if their length varies. If the latter is true, be sure that all of the bolts are evenly tightened on assembly.

5. Check the friction plate tabs for wear or damage. Check the clutch housing for indented wear caused by the tabs. Remove any burrs with a file or oilstone.

6. Check the corresponding splines of the clutch hub and steel plates for indented wear.

7. Check the condition of the lifter plate bearing. Rotation must be smooth, noiseless, and effortless. Replace the bearing if rotation is rough, the races loose, or rotation noisy.

Checking the pressure plate bearing for play

8. Check the condition of the clutch hub shaft splines. The hub must be a good snug fit on its shaft. If it is very loose, or if the hub splines show signs of wear or damage, replace it.

9. Check the pressure plate for cracks.

10. Check the condition of the clutch housing gear teeth. If any damage is noted replace the housing. Check the condition of the primary drive gear as well. Refer to the following section.

11. Check the clutch housing bearings for condition. If either of the bearings shows discoloration or damaged rollers or cages, replace both of them.

ASSEMBLY

1. Install the clutch shaft shim behind the clutch housing. Lubricate the housing bearings, then install the housing.

2. Fit the washer on the outside of the housing, then the collar.

3. Install the pressure plate.

4. Install one of the ordinary friction plates, then alternate steel and friction plates until all are installed. The *next to last* steel plate to be installed is different from the others. The *last* friction plate has slanted grooves and must be installed properly. Note the illustration.

5. Fit the clutch hub.

6. Lubricate the entire assembly with clean engine oil.

7. Install the clutch hub nut washer. "OUTSIDE" is marked on the washer, and it must be correctly installed.

8. Position the lockwasher correctly. Install and tighten the hub nut. Proper torque is 33–40 ft. lbs. Secure the engine as on removal to tighten the nut.

Bend up the tab on the lockwasher.

9. Install the lifter plate, springs, and spring bolts. Tighten the bolts gradually and in a cross pattern until all are secured.

10. If the shaft and adjuster in the clutch cover have been removed, be sure to lubricate the lifter shaft hole with an assembly lube before installation.

11. Be sure to use a new clutch case gasket and that the dowel pins are in place.

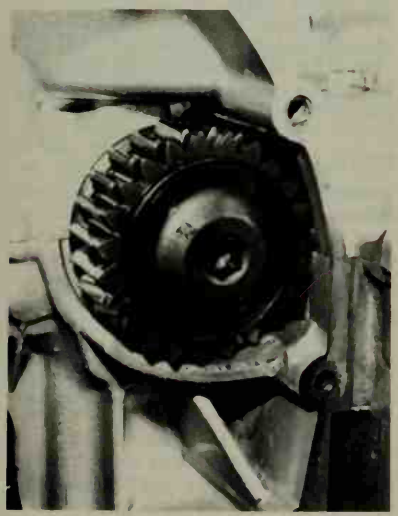
The next-to-last steel plate is different from the others

Be sure that the last friction plate is correctly installed. The grooves must be positioned as shown

Be sure to install the washer with the "Outside" mark facing outwards

Primary Drive Gear (1979–81)

REMOVAL



1. Remove the clutch assembly as outlined above.
2. Hold the primary gear with the special holder.
3. Loosen the gear bolt.
4. Remove the bolt, lockwasher, collar, and drive gear.

INSPECTION

Check the gear for wear and replace it if it shows worn or chipped teeth. Check for pitting of the gear teeth. This will be most obvious near the base of the teeth.

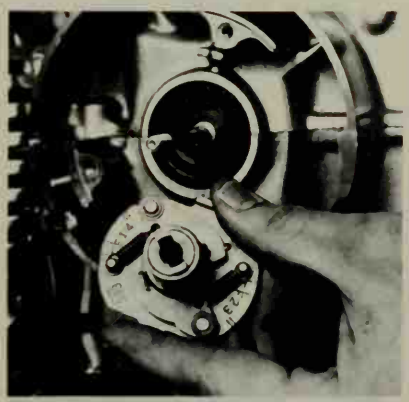
INSTALLATION

1. Install the drive gear with the larger gear facing outwards. Install the collar, aligning the hole in the collar with the pin in the drive gear.
2. Tighten the gear bolt to 60–72 ft. lbs.

Primary drive gear

Ignition Timing Assembly (1969–78)

REMOVAL



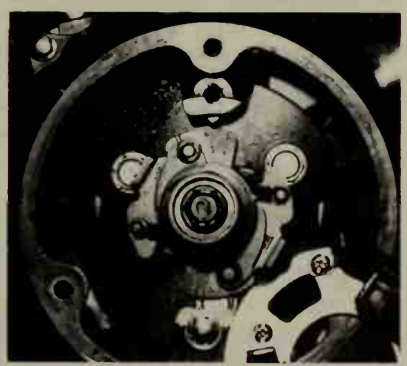
1. Remove the breaker points cover. Disconnect the two leads behind the engine.
2. Remove the small nut which secures the special nut used to turn the engine over.
3. Remove the three screws which secure the breaker plate and remove it.
4. Pull off the timing advance mechanism as a unit, taking care not to take apart the mechanism and breaker cam.
5. Remove the advancer shaft.

Removing the special nut

INSPECTION

1. The timing advance mechanism movement must be free. When the breaker cam is turned so that the weights move out to the fully extended position, releasing the cam should result in its returning to the original location. If it will not, try penetrating oil or the like to ease movement. Check for weak springs. Replace the unit if proper action cannot be obtained.
2. Check that the advancer shaft is not bent. Straighten or replace it if it is.

Removing the timing advance mechanism



INSTALLATION

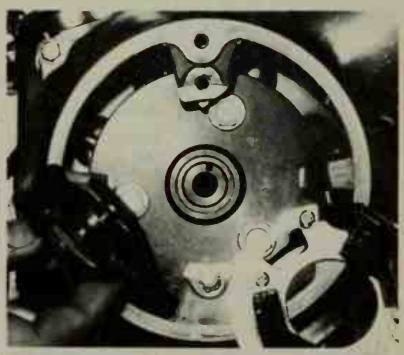
Installation is the reverse of removal. Note that the timing advance mechanism is located with a pin on the crankshaft.

Ignition Timing Assembly (1979–81)

REMOVAL

1. Remove the pulser generator cover.
2. Remove the left rear crankcase cover.
3. Scribe a line across the crankcase and the timing base plate to approximate timing.
4. Remove the two large phillips screws and remove the timing base plate and pulser generators.
5. Hold the crank steady by putting a wrench on the spacer, and remove spark advancer bolt. Remove the spark advance mechanism.

Timing advance mechanism



INSPECTION

1. The timing advance mechanism movement must be free. When the breaker cam is turned so that the weights move out to the fully extended position, releasing the cam should result in the cam's returning to the original position. If it will not, try penetrating oil or the like to ease movement. Check for weak springs. Replace the unit if proper action cannot be obtained.

INSTALLATION

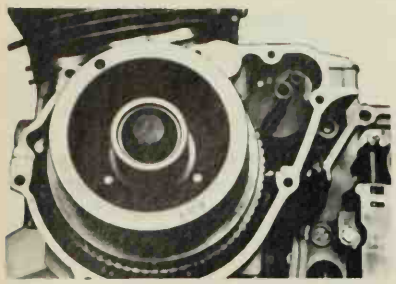
Installation is the reverse of removal. Note that the timing advance mechanism is located with a pin. The spacer must be aligned as well.

Tighten the advance mechanism bolt to 24–27 ft. lbs.

Locating pin must be noted when installing the mechanism

Alternator/Starter Drive (1969–78)

REMOVAL



1. Remove the crankcase drain plug and drain off the oil.
2. Remove the alternator cover.
3. Remove the alternator rotor mounting bolt. The rotor is a push-fit onto the tapered crankshaft. Remove the rotor with special tool No. 07933-3000000 or a suitable substitute.
4. Remove the starter clutch gear and the starter reduction gear.

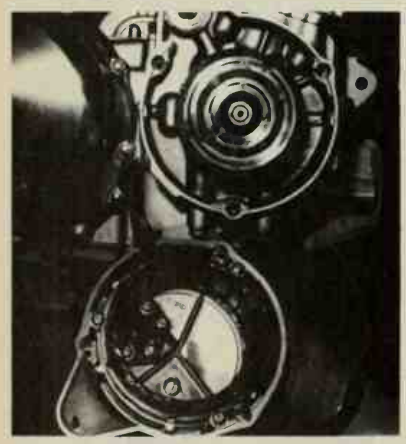
Alternator cover screws

INSPECTION

1. Refer to "Electrical System," for alternator tests.
2. Check the condition of the starter drive gears and replace them if the teeth are worn or broken.
3. The starter clutch should be replaced if defective, a condition indicated if the starter motor, but not the engine, turns over when the starter button is pushed.

Alternator rotor

INSTALLATION



Installation is the reverse of removal. Tighten the rotor bolt to 58–65 ft. lbs.

Alternator (1979–81)

REMOVAL

1. Remove the right side frame side cover. Disconnect the alternator wiring coupler.
2. Remove the alternator cover (3 bolts).
3. Remove the stator from the cover, if desired, by removing the five phillips screws.
4. Shift the transmission into gear and apply the rear brake. Remove the alternator rotor bolt.
5. Use the special alternator rotor puller to remove the rotor.

CAUTION: *Do not strike the rotor. Do not put the rotor anywhere it might pick up metal particles.*

Alternator components

Removing the rotor bolt

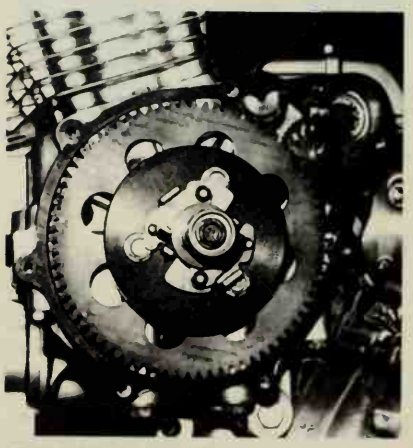
INSPECTION

1. Refer to "Electrical System" for electrical tests.
2. Check the length of each carbon brush. If worn to the scribed wear limit line, replace them.

Brushes can be removed by removing the mounting screws.

INSTALLATION

Installation is the reverse of removal. Tighten the rotor bolt to 58–72 ft. lbs.



Starter Drive (1979–81)

REMOVAL

1. Remove the left front crankcase cover. Remove the spark advance mechanism after removing the mounting bolt.
2. Remove the starter clutch assembly.
3. Remove the starter driven gear and shaft.

INSPECTION

1. Clean all components thoroughly in a safe solvent.

Starter drive components

2. Check the rollers for smooth operation. Check for wear, and replace them if any signs of it are evident.
3. Check the gear teeth for a chipped, worn, or pitted condition. Replace both gears if either is worn.
4. Check the outside diameter of the large starter drive gear. Replace it if it is less than 42.3 mm (1.66 in.).

INSTALLATION

1. Installation is the reverse of removal. Note the following points:

a. tighten the starter clutch lockbolts to 19–22 ft. lbs.

b. be sure to align the timing advance mechanism with its hole. The spacer needs alignment as well. Tighten the advance lockbolt to 24–27 ft. lbs.

Gearshift Mechanism (1969–78)

REMOVAL

1. After loosening the pinch bolt, carefully pull the gearshift lever off the splined shaft.
2. Drain the oil from the crankcase; then place a drip pan beneath the gearshift mechanism cover to catch any residue remaining.
3. Remove the screws which secure the rear section of the left crankcase cover and pull off the cover, taking care that the gearshift lever shaft oil seal is not damaged on the threads of the shaft.

If the cover resists removal, tap the top and side with a plastic mallet to break it loose.

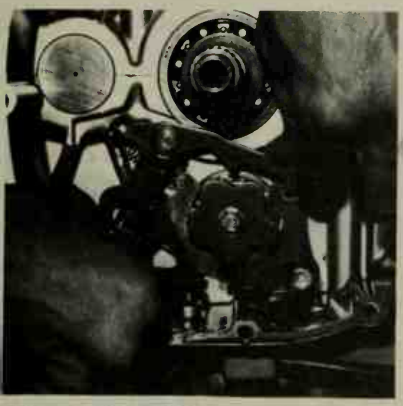
4. Disengage the fingers of the shift arm from the shift drum and pull out the arm.
5. Remove the two 6-mm bolts and take off the shift drum stopper and the shifter positive stopper.

INSPECTION

1. Check the fingers of the shift arm for wear or bent condition.
2. Check that all pins are properly located in the shift drum.
3. Check that the shift arm spring and stopper springs have proper tension and are not weak or broken.
4. Check the condition of the cover oil seal, and replace it if it leaks or the lips show signs of damage by prying it out with a small screwdriver. Press the new seal straight in. Grease the seal lips before installation.

INSTALLATION

Installation is the reverse of the removal procedure.



Gearshift Mechanism (1979–81)

REMOVAL

1. Drain the engine oil.
2. Remove the shift lever pinch bolt and very carefully pull the lever from its splined shaft.
3. Remove the rear brake pedal.
4. Run the clutch cable adjuster at the handlebar all the way in, and disconnect the cable from the lever at the engine.
5. Place a drip pan beneath the clutch cover, and remove it.
6. Remove the clutch assembly (see above).
7. Pull out the gearshift assembly.
8. Remove the shift drum stopper arm bolt and spring.
9. Remove the roller stopper plate bolt and the plate.
10. Remove the bearing stopper plate if

Gearshift mechanism

Removing the shift shaft

the bearing is going to be removed (engine disassembly required).

INSPECTION

1. Check the fingers of the shift arm for wear or a bent condition.
2. Check that all pins are properly located in the shift drum.
3. Check that the shift arm spring and stopper springs have proper tension and are not weak, corroded, or broken.
4. Check the condition of the left crankcase cover oil seal, and replace it if it leaks or the lips show signs of damage. Pry it out with a small screwdriver. Press the new seal straight in. Grease the seal lips before installation.

INSTALLATION

1. Install the bearing collar if it has been removed.
2. If the bearing retainer plate was removed, use a non-permanent thread-locking compound on the screw threads.
3. Install the roller stopper pins, plate, and bolt. Tighten it securely.
4. Install the drum stopper arm, bolt, and return spring.
5. Install the gearshift spindle assembly.
6. Rotate the spindle and check for smooth operation.
7. The remainder of the procedure is the reverse of disassembly.

Subtransmission

DISASSEMBLY

1. Remove the rider footpegs.
2. Remove the exhaust pipe heat shield. Remove the gear selector pedal and arm.
3. Drain the subtransmission oil. Remove the cover.
4. Remove the circlip, the washer, and the cotters.
5. Remove the smaller reduction drive gear and collar.
6. Remove the shift drum, shift fork, and shifter with splined collar.
7. Remove the collar and the larger reduction drive gear and washer.
8. Remove the shift drum stopper arm and spring. Remove the o-ring.
9. To remove the spring-loaded reduction driven gear a special tool must be used.

CAUTION: *Do not attempt to remove this gear without the special tool.*

10. Compress the reduction driven gear with the special tool and remove the cotters. Carefully release the tool noting that the gear will spring off unless the tool is backed off gradually.
11. Remove the dowel pins, reduction driven gear, damper lifter, spring, and spring seat.

INSPECTION

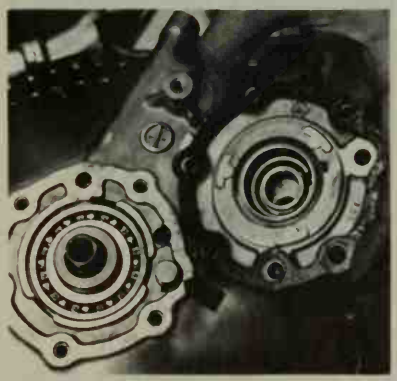
1. Check all gears for the usual signs of wear.
2. Check the components against the following specifications:

Drive gear ID: 31.04 mm (1.222 in.)
Gear collar OD: 30.94 mm (1.218 in.)
Driven gear ID: 25.04 mm (0.982 in.)
Driven gear shaft OD: 24.95 mm (0.982 in.)
Shift fork finger thickness: 5.7 mm (0.224 in.)

If any component fails to meet these service limits, it must be replaced.

ASSEMBLY

Assembly is the reverse of removal. Install the drive gears so that the "OUT" mark stamped on each gear does face the proper way.



When fitting the drive gear collar, be sure to align the collar and countershaft oil holes.

CRANKCASE COVER COMPONENTS (AUTOMATIC TRANSMISSION MODELS)

Torque Converter

REMOVAL

1. Drain the oil.
2. Remove the rear brake pedal and the right-side footpeg.

Removing the torque converter case cap. Note the check valve (arrow)

3. Remove the chromed protector cover.
4. Remove the torque converter case cap. Note the spring-loaded check valve behind the cap.
5. Remove the securing screws and take off the torque converter case. Note the oil guide pins at the case joint.
6. To remove the converter assembly as a unit, a special tool must be used.
7. To disassemble the converter, remove the securing bolts and separate the components.
8. Disassemble the stator, if so desired, by removing the snap-rings. Carefully separate the components noting their positions.

INSPECTION

1. Check the inside surfaces of the case cap for scoring or wear. Check the bushing for wear or excessive cap-to-bushing clearance.
2. Check the valve spring for a weakened condition.
3. Check the stator hub outside diameter. Replace it if less than 39.9 mm (1.571 in.). Inside diameter service limit is 26.1 mm (1.028 in.).
4. Check the thickness of the stator side plates and replace them if less than 5.9 mm (0.232 in.).
5. Check thickness of the thrust washers and replace them if less than 1.9 mm (0.075 in.).
6. With the stator assembled and positioned on its shaft, it should be possible to turn the one-way clutch in the counterclockwise direction only.
7. Check the torque converter cover bushing diameter. Serviceable limit is 13.0 mm (0.512 in.).

INSTALLATION

Installation is the reverse of removal. Tighten turbine bolts to 9–12 ft. lbs., and thoroughly lubricate all parts during assembly.

Ignition Timing Assembly

Refer to "Crankcase Cover Components: Manual Transmission," above; procedures are identical.

Alternator/Starter Drive

Refer to "Crankcase Cover Components: Manual Transmission," above; procedures are identical. Tighten the rotor bolt to 72–87 ft. lbs.

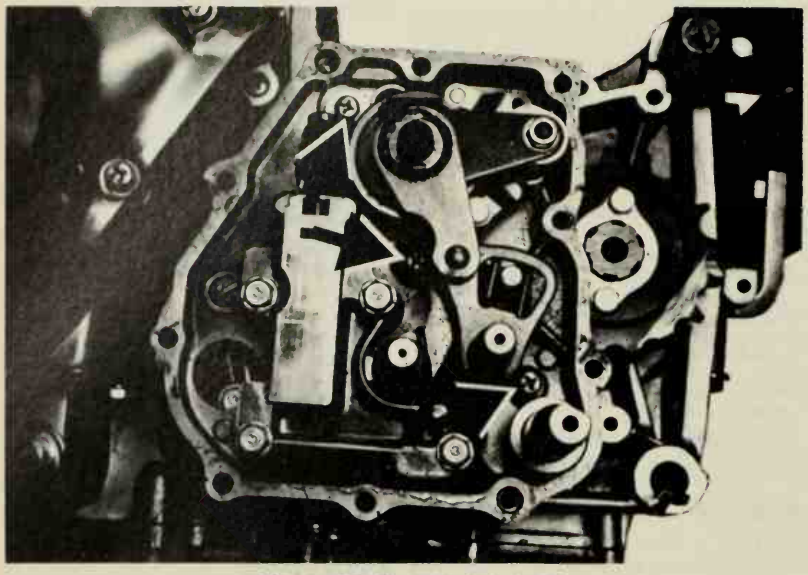
Oil Pump

REMOVAL

1. Drain the oil. Place a drip pan beneath the left crankcase cover to catch any residue.
2. Remove the left-side footpeg, kick-start rubber, gearshift lever, and the neutral return arm.
3. Remove the screws securing the rear portion of the left crankcase cover. If the cover resists removal, tap gently with a plastic mallet to free it.
4. Remove the three screws and take off the left case. Unbolt and remove the oil pump.

INSPECTION

Refer to "Lubrication Systems," for oil pump inspection procedures.



INSTALLATION

Installation is the reverse of removal.

Shifter Mechanism

REMOVAL

1. Drain the oil. Place a drip pan beneath the left crankcase cover to catch any residue.
2. Remove the left-side footpeg, gearshift and neutral return levers, and kick-start rubber.
3. Remove the screws securing the rear portion of the left crankcase cover. If the cover resists removal, tap gently with a plas-

Gearshift case securing screws (arrows)

Oil pump fastening bolts

tic mallet to free it. Pull the cover straight out to avoid damage to the oil seals.

4. Remove the ratchet guide nut. Remove the gearshift inner piece, taking care that the spring-loaded pawls do not fly off.

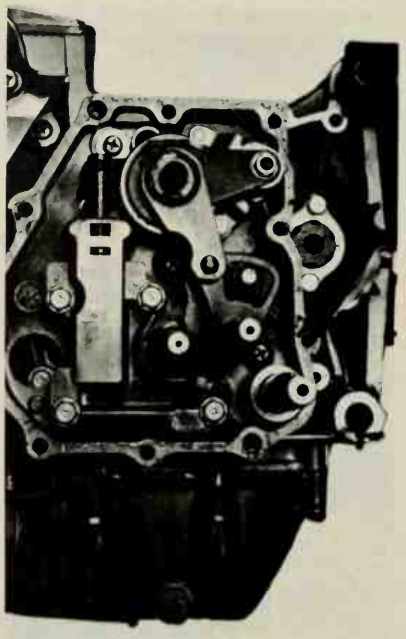
5. Remove the neutral keeping spindle and the shift spindle.

6. Remove the shift stoppers and the gearshift outer piece.

7. Remove the manual valve and plate.

INSPECTION

1. Check all parts for wear.



2. Check the shift pawls for chipping or wear.

3. Check that the springs have sufficient tension.

INSTALLATION

Installation is the reverse of removal.

Be sure that the springs are preloaded for tension. Also make sure that the arm of the neutral return arm is set under the pin of the manual valve.

Left crankcase cover components

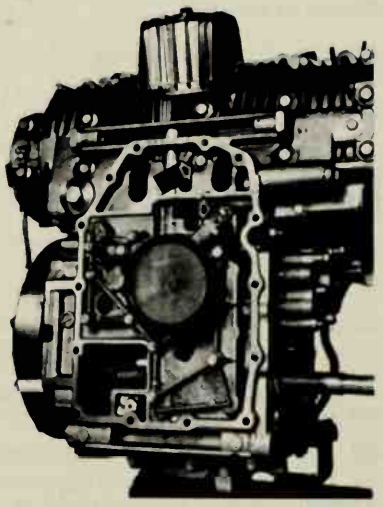
LOWER END (1969–78)

Working procedures for the lower end are similar for all models. The primary difference lies in the procedure for the removal of the crankcase cover components in the automatic versus the manual transmission machines.

Disassembly

1. Remove the oil filter case. Remove the engine from the frame following the procedure outlined at the beginning of this chapter.

2. Referring to the preceding sections, remove the clutch or torque converter case, breaker point assembly and shaft, alternator and starter drive, shifter mechanism, and oil pump (automatic).



It is not necessary to remove the clutch or torque converter if only the crankshaft is going to be serviced. Conversely, service work to the transmission does not require removal of the alternator rotor.

3. Remove the bearing retainer for the transmission countershaft bearing (manual transmission).

4. Remove the starter motor cover. Remove the top end components: cam chain tensioner, head, cylinders, and pistons.

5. Remove the oil pan.

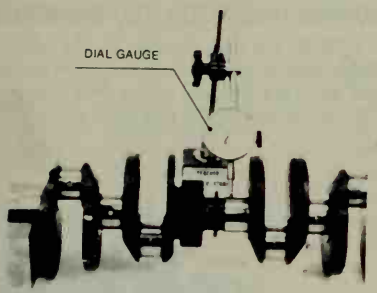
6. Remove all of the upper crankcase bolts. Turn the engine over and remove the lower crankcase bolts. Separate the crankcase halves.

Lower crankcase bolts (750A). Note bolts accessible after removing oil pan (arrows)

7. Lift out the mainshaft (manual transmission) or primary shaft (automatic), and disengage the primary chain. Lift out the shaft.

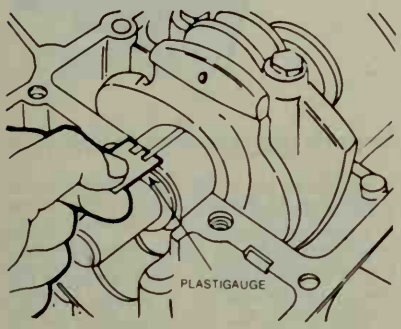
INSPECTION

Check crankshaft run-out by supporting the ends of the crankshaft in V-blocks and rotating it slowly while reading with a dial gauge at the center journal. If run-out exceeds 0.05 mm (0.002 in.), the crankshaft should be replaced.



Run-out in this case is one-half of the total indicated dial gauge reading.

MAIN BEARINGS



1. Journal wear can be checked using a material such as plastigauge. Cut strips of plastigauge to fit across each bearing, install the crankshaft and lower crankcase, and torque the 8-mm lower crankcase bolts in the correct sequence to 15 ft. lbs. Do not turn the crankshaft. Unbolt the case, lift out the crankshaft, and measure the plastigauge with the scale provided. If clearance exceeds 0.08 mm (0.0032 in.), the bearings should be replaced. Do not reuse bearings that are damaged in any way.

Standard bearing clearance is 0.020–0.046 mm (0.008–0.0018 in.).

2. Inspect the journals for scoring and damage. Measure the journal diameter in several places to check for ovality and taper.

Checking crankshaft run-out with a dial gauge

Measuring the main bearing oil clearance

Maximum acceptable variation of journal diameter is 0.05 mm (0.002 in.).

NOTE: *When the bearing halves are installed in the crankcases, the tops of the bearings should protrude 0.068–0.98 mm (0.0027–0.0039 in.). above the crankcase flanges.*

Main Bearing Selection

1. In most cases, the original bearing inserts can be replaced with new bearings of the same size. Size identification is made by the color code on the end surface of each bearing. Simply replace each main bearing insert with one of the same color.

2. It may be desirable, however, to measure the diameter of the crankshaft journals so that journal wear (if any) can be taken into account when selecting bearing size. In this case, it will be necessary to convert journal sizes into code letters so that the appropriate bearings can be selected. After the diameter of each journal has been measured, refer to the following chart for journal size codes.

JOURNAL DIAMETER CODE CHART

Journal Diameter	*Code*
36.000–35.995 mm	A
35.995–35.990 mm	B
35.990–35.985 mm	C

NOTE: *The original (new) crankshaft journal size codes, which you may want to refer to, can be found stamped on the side of the crankshaft weight adjacent to the primary drive sprocket. (See the illustration.) However, on very early engines (up to engine number CB 750E-1015587), Japanese symbols were used instead of letters for journal size coding. Disregard these symbols and rely on your own journal diameter measurements.*

Crankshaft journal size codes are interpreted as follows: J L - A A B B C

J Code designation for crankshaft journal.
L Indicates that the journals are designated from the left side of the crankshaft.
A Indicates that A is the size code of the left end crankshaft journal.
A Indicates that A is the size code of the second journal from the left end.
B Indicates that B is the size code of the third journal from the left end.
B Indicates that B is the size code of the fourth journal from the left end.
C Indicates that C is the size code of the right end crankshaft journal.

Note that the code given above is only an example of a typical code, and that others will differ.

3. After the journal size codes have been determined, locate the main bearing seat diameter code, which is stamped on the lower crankcase as shown in the accompanying illustration. For reference purposes, the code letters convert as follows:

BEARING SEAT DIAMETER CODE CHART

Seat Diameter	*Code*
39.000–39.008 mm	A
39.008–39.016 mm	B
39.016–39.024 mm	C

4. Finally, using the journal and seat diameter code letters you have arrived at for each bearing, select the proper bearing color codes.

BEARING SELECTION CHART

	Journal Code		
Seat Code	*A*	*B*	*C*
A	yellow	yellow	green
B	green	green	brown
C	brown	brown	black

CONNECTING RODS AND BEARINGS

NOTE: *Mark the location of each rod before removal.*

Rod Bearing Selection

1. To check rod-bearing-to-crankpin clearance, cut a strip of plastigauge and place it across the bearing shell, as when checking main bearing clearance. Install the rod bearing cap and tighten the nuts to 14.5 ft. lbs. Do not turn the crankshaft or move the connecting rod. Remove the cap and measure the plastigauge with the scale. Maximum acceptable clearance is 0.08 mm (0.0032 in.). If clearance exceeds this amount, the bearings should be replaced. Standard clearance is 0.020–0.046 mm (0.008–0.0018 in.).

2. In most cases the original bearings can be replaced with new bearings of the same size. Size identification is made by the color code on the end surface of each bearing. Simply replace each rod bearing with one of the same color.

It may be desirable, however, to measure the diameter of the crankpins so that wear can be taken into account when selecting bearing size. In this case it will be necessary to convert crankpin sizes into code numbers so that the appropriate bearings can be selected, in the same manner as main bearing selection. After the diameter of each crankpin has been measured, refer to the following chart for crankpin size codes.

CRANKPIN DIAMETER CODE CHART

Crankpin Diameter	*Code*
36.000–35.995 mm	3
35.995–35.990 mm	4
35.990–35.985 mm	5

3. After the crankpin size codes have been determined, locate the rod bearing seat diameter code, stamped on the side of the connecting rod big end.

For reference purposes, the seat diameter code numbers convert as follows:

BEARING SEAT DIAMETER CODE CHART

Seat Diameter	*Code*
39.000–39.008 mm	1
39.008–39.016 mm	2
39.016–39.024 mm	3

4. Finally, using the crankpin and seat diameter code numbers you have arrived at for each bearing, select the proper bearing color.

BEARING SELECTION CHART

	Crankpin Code		
Seat Code	*3*	*4*	*5*
1	yellow	yellow	green
2	green	green	brown
3	brown	brown	black

Connecting Rod Replacement

If a connecting rod is to be replaced, a replacement of the same weight code as the original should be selected. Rod weight can be determined by the code letter stamped on the rod bearing cap. When replacing all four rods, ensure that the weight codes are the same. Rod weight includes the bearing cap and bolts, but does not include the bearing shells.

NOTE: *Prior to engine number CB 750E-1017739, Japanese symbols were used for the rod weight code. The connecting rods used in engines produced after this engine number use letter codes, and the machined surfaces on either side of the big end are slightly redesigned. The old and new type rods are interchangeable; however, when replacing an old-type rod with a new-type, always select one having a weight code of A, regardless of the symbol that appears on the old rod.*

Assembly

1. Fit the cam and primary drive chains onto the crankshaft and install the connecting rods in their original positions, as marked. Tighten the rod bolts to 15 ft. lbs. Lubricate the bearings and install the crankshaft in the upper crankcase.

2. Fit the primary chain over the transmission mainshaft or primary shaft sprocket and install the shaft on the upper crankcase.

Make sure that the shaft bearing set rings are positioned in the bearing seats before installing the shaft.

3. Install the oil collar, o-ring, and two dowel pins on the upper crankcase. Thoroughly clean both crankcase mating surfaces and apply a thin, even coat of gasket cement to only one of the surfaces.

4. Carefully fit the lower crankcase half on the upper one. Install and tighten the ten 8-mm lower crankcase mounting bolts to 17–18 ft. lbs. Next, install the 6-mm mounting bolts and tighten to 8 ft. lbs.

Be sure to tighten the bolts gradually and in the order shown (cross pattern).

5. Turn the engine right-side up and install the upper crankcase mounting bolts; torque them to the same specification.

6. The remainder of the procedure is the reverse of removal. Refer to the individual sections for component installation.

LOWER END (1979–81)

Disassembly

1. Remove the oil filter case. Remove the engine from the frame following the procedures outlined at the beginning of this section.

2. Referring to the preceding sections, remove the clutch case, pulser generator assembly, alternator, starter drive, and shift mechanism. Remove the subtransmission (900).

It is not necessary to remove the clutch if only the crankshaft is going to be serviced. Conversely, service work to the transmission does not require removal of the alternator rotor.

3. Remove the bearing retainer for the countershaft bearing (behind the shift assembly).

4. Remove the starter motor cover. Remove the top end components: head, cylinders, and pistons.

5. Remove the oil pan. Remove the oil strainer.

6. Remove the upper crankcase bolts. There are 8 of them, all located behind the cylinders.

7. Turn the engine over and remove all of the lower crankcase bolts. There are 24.

8. Separate the crankcase halves. If they seem stuck, first check that all of the fasteners have been removed. Next, tap around the crankcase mating surfaces with a plastic mallet.

CAUTION: *Do not attempt to pry the crankcases apart.*

The crank and transmission shafts will remain in the upper case half.

The internal gearshift mechanism will come away with the lower crankcase half.

9. Lift out the primary shaft and disengage the chain. Lift out the crankshaft assembly. Remove the transmission shafts.

Inspection

Check crankshaft run-out by supporting the ends of the crankshaft in v-blocks and rotating it slowly while reading with a dial gauge at the center journal. If run-out exceeds 0.05 mm (0.002 in.), the crankshaft should be replaced.

Run-out in this case is one-half of the total indicated dial gauge reading.

CAM CHAIN

1. Place the cam chain over the intake cam sprockets. Secure one sprocket, pull at the other with about 29 lbs. tension.

2. Measure the chain length. If it exceeds 311.8 mm (12.28 in.), the cam chain should be replaced.

PRIMARY CHAIN

Refer to "Manual Transmission, 1979–1981," below.

PRIMARY CHAIN TENSIONER

1. Remove the spring and plunger.

2. Remove the nut, oil line, and tensioner fluid valve.

3. Remove the slipper assembly.

4. Check the holes in the oil lines and plunger for blockage.

5. Clean all parts with a safe solvent.

6. Check the slipper for damage or excessive wear, and replace if necessary.

6. Installation is the reverse of removal.

MAIN BEARINGS

1. Journal wear can be checked using plastigauge. Cut strips of plastigauge to fit across each bearing after cleaning all the oil residue from the bearing surface. Be sure that the material is not placed across the bearing holes. Install the main bearing inserts on the journals of the lower crankcase half and tighten the crankcase bolts gradually and in a cross pattern to the following torques:

crankshaft 8 mm bolts	15–18 ft. lbs.
crankshaft 8 mm bolts	15–18 ft. lbs.
6 mm bolts	7–10 ft. lbs.
10 mm bolts	33–36 ft. lbs.

Remove the lower crankcase half and check the bearing clearance.

Crankshaft bearing serviceable limit is 0.08 mm (0.003 in.). If clearance exceeds this limit, the bearing inserts should be replaced. Always replace inserts as a set, even if only one is over specification.

Standard bearing clearance is 0.020–0.060 mm (0.00080.0024 in.).

2. Inspect the journals for scoring or other visible signs of wear. Measure the journal diameter in several directions to check for ovality and taper. Maximum acceptable variation out-of-round of the journals is 0.05 mm (0.002 in.).

3. To find the correct main bearing insert first find the crankcase inside diameter code numbers which are stamped on the back of the upper crankcase half. The letters "A", "B," and "C" indicate crankcase journal inside diameters from left to right.

4. Next, check the crank journal outside diameter codes stamped on the crank flywheels. These, too, will be coded "A," "B," and "C."

5. Refer to the following chart to determine the correct bearing insert replacement:

CONNECTING RODS AND BEARINGS

1. With the rods installed on the crank, check side clearance between the rod cap and the crank flywheel with a feeler gauge. Serviceable limit is 0.3 mm (0.01 in.).

Measuring connecting rod side clearance

Standard big end side clearance is 0.05–0.20 mm (0.002–0.008 in.).

2. Remove the rods.

NOTE: *Mark each rod for location, direction of installation, and always install the caps on the rods in the original manner. Caps are neither interchangeable nor reversible.*

3. Check each of the rod bearing inserts for scoring. The inserts should be featureless. If scoring or signs of wear are noted, the inserts should be replaced.

4. Check the condition of the crankshaft journals. They should be very shiny, and have a flawless surface. If scored, the journals may have to be turned down on a lathe.

5. Connecting rod bearing inserts are color-coded according to size. First determine whether clearance is excessive by using plastigauge to determine bearing clearance. Lay a strip of the material across the journal. Fit the rod, being sure it is installed on the correct journal, in the proper direction, and that the bearing cap is facing the original direction. Tighten the cap to 22–25 ft. lbs.

NOTE: *Be sure not to turn the rod when the plastigauge is in place.*

6. Maximum acceptable rod clearance is 0.08 mm (0.003 in.).

Standard clearance is 0.020–0.060 mm (0.008–0.0024 in.).

7. If the measurement shows that the rod bearings need replacement, proceed as follows:

Check the crankpin outside diameter code stamped on the flywheels of the crank.

Both codes will be "1," "2," or "3."

Refer to the chart to determine the correct color bearing insert replacement:

8. When fitting new bearing inserts, be sure to align the oil hole in the bearing insert with the hole in the connecting rod.

			Main Journal O.D. Code		
			A	B	C
			35.992–36.000 mm	35.984–35.992 mm	35.975–35.984 mm
Case I.D. Code	A	39.000–39.008 mm	D (Yellow)	C (Green)	B (Brown)
	B	39.008–39.016 mm	C (Green)	B (Brown)	A (Black)
	C	39.016–39.024 mm	B (Brown)	A (Black)	E (Blue)

Connecting Rod I.D. Code		Crankpin O.D. Code 1 35.992–36.000 mm	Crankpin O.D. Code 2 35.984–35.992 mm	Crankpin O.D. Code 3 35.975–35.984 mm
1	39.000–39.008 mm	E (Yellow)	D (Green)	C (Brown)
2	39.008–39.016 mm	D (Green)	C (Brown)	B (Black)
3	39.016–39.024 mm	C (Brown)	B (Black)	A (Blue)

9. Be sure to lubricate the rod bearings thoroughly before assembly.

CONECTING ROD REPLACEMENT

If a connecting rod itself is to be replaced, a replacement of the same weight code as the original should be selected. Rod weight can be determined by the code letter stamped on the rod big end. Factory-fitted rods are stamped "A" to "G." Replacement rods are stamped "B," "D," and "F." Replacements are to be made as follows:

Factory code	Replacement code
A, B	B
C, D, E	D
F, G	F

Assembly

1. When fitting the rods to the crankpins, be sure that the rods are fitted to the original locations, that the caps are correctly installed, and that the oil hole in the rod points towards the *rear* of the engine.

2. Tighten the rod caps to 22–25 ft. lbs.

Cap bolts should be tightened gradually and evenly. Check that the rod can turn freely after each tightening sequence.

NOTE: *Be sure that the rod bearings are well lubricated before installation.*

3. Be sure that the crankcase mating surfaces are clean and free of any old gasket compound.

4. Apply a liquid gasket sealant to the lower crankcase half mating surface.

CAUTION: *Keep the sealant away from main bearings.*

5. Fit the cases together being sure that they mate all the way around. Do not force the cases together. Be sure that the shift forks are fitted into the gear grooves when assembling.

6. Tighten the crankcase bolts gradually and evenly beginning at the center of the crank and working outwards. Proper torques are as follows:

crankshaft 8 mm bolts	15–18 ft. lbs.
crankcase 8 mm bolts	15–18 ft. lbs.
6 mm bolts	7–10 ft. lbs.
10 mm bolts	33–36 ft. lbs.

Crankshaft bolts should be clean and well lubricated for accurate torque readings.

Be sure that the washers are in place beneath the crank bolts.

7. Tighten the upper crankcase half bolts starting at the front.

MANUAL TRANSMISSION (1969–78)

Primary Drive and Kick-Start Mechanism

PRIMARY DRIVE CHAIN INSPECTION

An automatic primary chain tensioner is incorporated to reduce chain vibration, wear, and noise. However, it is possible for the chain to stretch beyond the range of the tensioner, resulting in excessive primary drive noise. Chain wear can be checked without disassembling the engine. Proceed as follows:

1. Drain the oil from the crankcase.

2. Unscrew the ten oil pan mounting bolts and drop the pan.

3. Measure the distance between the chain tensioner bracket and the oil pan mounting flange with a vernier caliper, as shown. The chain should be replaced if the measurement exceeds 70 mm (2.76 in.).

4. Examine the tensioner roller and replace it if damaged or noticeably worn.

DISASSEMBLY

Disassembly of the primary drive or kickstart mechanism entails splitting the crankcases. The crankcases can be separated *without* disassembling the top end components, however, unless replacement of the primary chain is necessary. Refer to the "Lower End" section, above.

Primary Drive

To remove the primary drive chain, simply lift the crankshaft out of the case and slip the chain off. If necessary, the mainshaft chain sprocket can be removed from the shaft and replaced. However, if the crankshaft sprocket is worn or damaged, the crankshaft itself must be replaced.

Kick-Start Mechanism

1. To disassemble the kick-start mechanism, first remove the kick-start shaft retaining pin and withdraw the shaft. Remove the gear assembly and return spring. Finally, take off the ratchet spring and remove the kick-start pawl.

2. Check to make sure that the gear turns smoothly in one direction and locks in the other. The kick-start shaft diameter should not measure less than 19.93 mm (0.785 in.), and the inside diameter of the gear (shaft bore) should not exceed 20.08 mm (0.790 in.). Replace parts as necessary.

3. Install the gear, kick-start flange, and return spring together in the lower crankcase. Hook the end of the spring on the case and force the flange down with a screwdriver to hook it on the pin. Install the kick-start shaft and shaft retaining pin.

ASSEMBLY

Reassemble the engine in accordance with the assembly procedures given in the "Lower End" section, above. Install the engine in the frame and refill the engine with oil. Before starting the engine, crank it over with the starter (with the kill switch off) until oil pressure is developed.

Gear Set and Shifter Mechanism

DISASSEMBLY

1. Remove the engine from the frame, following procedures outlined in the beginning of this chapter. Remove the crankcase cover components according to the procedures given above.

2. Remove the countershaft bearing retainer.

3. Remove the upper crankcase mounting bolts. Turn the engine over and remove the lower crankcase bolts; separate the cases.

NOTE: *It is not necessary to remove the top end components to service the gear set or shifter mechanism.*

4. Lift out the complete mainshaft and disengage the primary chain. Remove the final driveshaft oil guide and lift out the driveshaft.

5. Pull out the shift fork shaft and remove the forks.

6. Unscrew the neutral detent (stopper) bolt, remove the plunger, and remove the shift drum from the crankcase.

7. Remove the outer (left-side) countershaft ball bearing, slide the countershaft fifth gear off the shaft, and lift out the countershaft assembly.

8. The inner (right-side) countershaft is necessary. The bearing should be removed with a slide-hammer type puller (Honda No. 07048-30025). Gently heating the case may facilitate removal.

Inspection

NOTE: *Do not disassemble the gear set unless inspection shows that replacement of individual gears is necessary. Gear shaft circlips are not reusable and must be replaced with new ones whenever the gear set is taken apart.*

If the gear set is disassembled, carefully lay out each piece in the order it is removed to facilitate reassembly.

1. Flush the transmission shaft bearings with clean motor oil and check operation. Bearing rotation must be smooth, effortless, and quiet. There must be no play between the inner and outer bearing races. If damage is noted, replace the bearings as a set.

2. Install the countershaft and mainshaft assemblies in the crankcase and measure gear backlash with a dial gauge. "Backlash" is the amount of movement noticeable in a gear when the gear with which it meshes is locked in place. Maximum acceptable backlash is 0.20 mm (0.008 in.) for all five sets. Replace any set of gears over this limit.

Note that gears are always replaced in pairs.

3. Check the gear teeth for damage, wear, or pitting. Pay close attention to the very

base of the teeth. Gears are surface-hardened, and if this hardened layer is damaged, what is left will not last long. Check the engaging dogs and/or dog slots on each gear for chipping or wear. Check that splined gears are a good fit on their shaft (neither too loose nor too tight) and that the splines on the shafts and on the gears are in good condition. Check that gears with plain bores can rotate freely but are not too loose on their shafts. Check all parts for damage due to overheating or lack of lubricant.

4. Compute gear-to-shaft clearance (bushing clearance) of gears C_1, C_2, C_3, M_4, and M_5 by measuring the shaft diameter and comparing it to the inside diameter of the gears. Maximum acceptable clearance is 0.18 mm (0.007 in.). Replace the gear, bush, or shaft if any gear has clearance in excess of this amount.

5. Measure the thickness of the shift fork fingers. Replace any fork whose fingers measure less than 6.1 mm (0.24 in.) thick.

6. Measure the diameter of the shift drum guide pin on each shift fork. Minimum acceptable diameter is 6.6 mm (0.26 in.). Replace the fork if pin diameter is less than this.

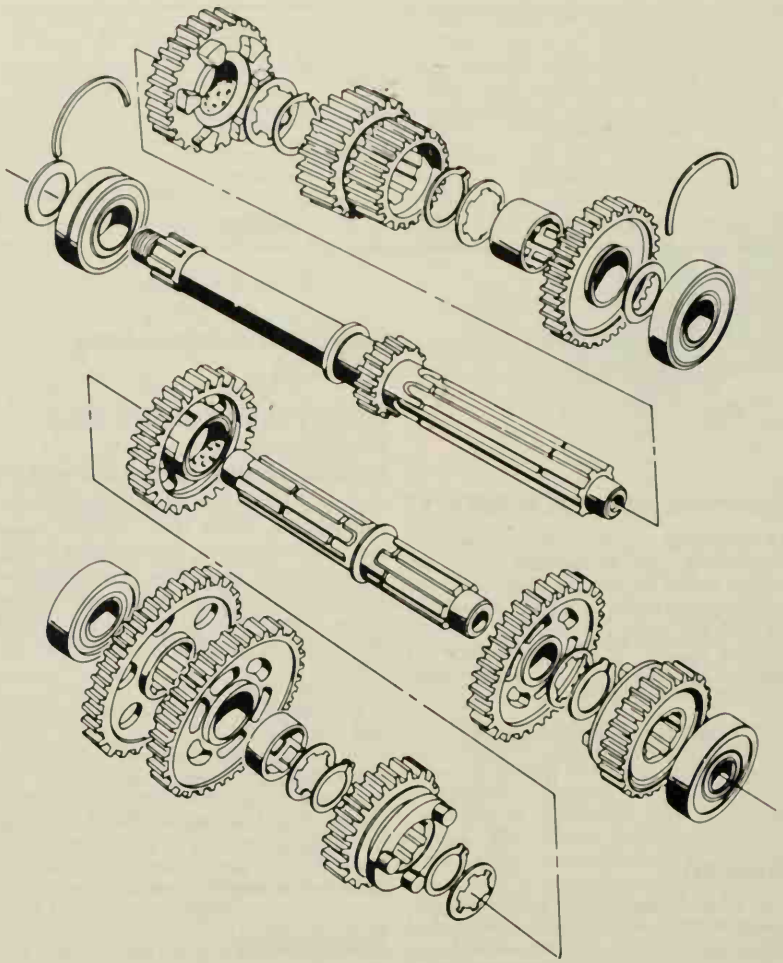
7. Check the inside diameter of each fork. Maximum acceptable inside diameter is 13.04 mm (0.513 in.). Check shift fork shaft diameter at several places along its length. The fork must not be less than 12.9 mm (0.508 in.) thick at any place or replacement is in order. Roll the shaft along a flat surface and check that it is not bent. If it is, straighten or replace the shaft.

8. Examine the shift drum cam grooves for damage and wear. Measure the diameter of the drum. Replace it if the drum is worn to less than 11.95 mm (0.515 in.) on the right side, or 35.92 mm (1.414 in.) on the left side.

Assembly

1. Assemble the gear set components onto their shafts. Use *new* circlips. Fit the circlips with the smooth edge against the thrust washers.

2. Install the right-side countershaft bearing in the case if it was removed. Installation will be facilitated by chilling the bearing for several hours before installation. Alternately, heat the case gently.



3. Install the countershaft with gears in place. Fit the countershaft fifth gear onto the shaft, then the left-side bearing.

4. Install the shift drum and neutral plunger. Neutral position on the shift drum is at the depression on the drum.

5. Install the shift forks with the forks marked "R" and "L" fitted to the grooves in the countershaft fourth and fifth (C4 and C5) gears, respectively. The fork marked "C" is fitted to the mainshaft second and third gear unit. The pins at the back of the shift forks should be located in the shift drum cam grooves. Install the fork shaft into the case and through the forks.

6. Place the bearing set ring in the bearing seat and install the final driveshaft assembly in the upper crankcase. Install the final driveshaft oil guide.

7. Mount the primary chain on the mainshaft sprocket and lower the mainshaft assembly into place. Do not forget to position the bearing set rings in the bearing seats before installing the mainshaft. Make sure that the transmission is in neutral before assembling the cases.

Transmission assembly (1969–1978)

8. The remainder of assembly is the reverse of disassembly. Be sure to tighten the crankcase bolts to the proper torque in the proper order. For specifications and illustrations, refer to the assembly procedure in the "Lower End" section, above.

MANUAL TRANSMISSION (1979–81)

Primary Chain

1. Place the primary chain over the primary driven gears. Secure one gear, apply 79 ft. lbs. of torque to the other.

2. Measure the chain length. If the primary chain measures more than 131.1 mm (5.16 in.) in length, replace it.

Primary Shaft

1. The components of the shaft can be removed after removing the primary drive gear lockbolt.

2. Check for scoring of the shaft surfaces and damage to the splines. Replace the shaft if such wear is noted.

3. Check the gears for chipped, worn, or pitted teeth. If any damage is noted, replace the gear and the gear with which it meshes.

4. Check the gear bearings for looseness, noisy rotation, or visible damage to the balls. Replace as a set if either is damaged.

Gear Set

NOTE: *Do not disassemble the gear set unless inspection shows that replacement of individual gears is necessary. Gear shaft circlips are not reusable and must be replaced with new ones whenever the gear set is taken apart.*

If the gear set is disassembled, carefully lay out each piece in the order it is removed to facilitate reassembly.

1. Flush the transmission shaft bearings with clean motor oil and check operation. Bearing rotation must be smooth, effortless, and quiet. There must be no play between the inner and outer bearing races. If damage or wear is evident, replace the bearings as a set.

2. Install the countershaft and mainshaft assemblies in the crankcase and measure gear backlash with a dial gauge. "Backlash" is the amount of movement noticeable in a gear when the gear with which it meshes is locked in place. Maximum acceptable backlash is 0.12 mm (0.005 in.) for all gear pairs of the 750. Standard backlash for the 750 is 0.024–0.074 mm (0.0009–0.0029 in.). For the 900, maximum acceptable backlash is 0.15 mm (0.006 in.). The standard backlash is 0.023–0.117 mm (0.0009–0.0046 in.).

Note that gears are always replaced in pairs.

3. Check the gear teeth for wear, damage, or pitting. Pay close attention to the very base of the teeth. Gears are surface-hardened, and if this hardened layer is damaged or worn away, what is left will not last long. Check the engaging dogs and/or dog slots on each gear for chipping or wear. Check that splined gears are a good fit on their shaft (neither too loose nor too tight) and that the splines on the shafts and on the gears are in good condition. Check that the gears with plain bores can rotate freely, but are not too loose on their shafts. Check all parts for damage due to overheating or lack of lubrication. This is indicated many times by bluish discoloration of the components.

4. Check the gear inside diameter of the mainshaft 4th and 5th gears and the countershaft 1st and 3rd gears. Compare the reading to the serviceable limit given in the specifications chart at the end of this section.

5. Check the outside diameter of the mainshaft 5th gear and countershaft 1st gear. Check the inside diameter of the countershaft 1st gear.

Compare the measurements to the specifications given at the end of this section.

6. Measure the mainshaft outside diameter at the spot on which the mainshaft 4th gear rides. If less than 27.93 mm (1.10 in.), replace the mainshaft.

7. Measure the diameter of the countershaft at the places where the countershaft 1st gear bushing and the countershaft 3rd gear ride. Compare to the specifications at the end of the section.

8. Compare the gear to shaft or bushing to shaft clearances. It should not exceed 0.10 mm (0.004 in.) for mainshaft 4th gear to shaft, countershaft 1st to its bushing, countershaft 1st bushing to its shaft, or countershaft 3rd to the shaft. It should not exceed 0.12 mm (0.005 in.) for the mainshaft 5th gear to its bushing.

Shift Drum

1. To remove the shift drum assembly from the case half, remove the bearing stopper plate. Take out the shift fork shaft and the shift forks. Remove the shift drum.

2. Measure the thickness of the shift fork fingers. Replace any fork whose fingers measure less than 6.1 mm (0.24 in.) thick.

3. Check each fork for wear or chipping of the guide pin and replace if the pin is not in good condition.

4. Check the inside diameter of each fork. Maximum acceptable inside diameter is 13.04 mm (0.513 in.). Check shift fork shaft diameter at several places along its length. The fork must not be less than 12.9 mm (0.508 in.) thick at any spot or replacement is in order.

Roll the shaft along a flat surface and check that it is not bent. If it is, straighten or replace it.

5. Examine the shift drum pin grooves for damage and wear.

6. Installation is the reverse of removal. Note that the shift forks are not interchangeable. Be sure to use a non-permanent thread-locking compound on the shift drum bearing retainer screw threads. The shift fork shaft should be a fairly snug fit in the shaft holes in the case. Check for wear or burrs in these holes.

Transmission Assembly

1. If the gear sets have been removed from the shafts, use *new* shaft circlips. Fit the circlips with the smooth edge against the thrust washers.

2. The mainshaft bearing is press-fit on its shaft and should be driven on with a special tool or a suitable drift.

3. Be sure to align the oil holes in any gears or bushings with the oil holes in the respective shaft.

The mainshaft 5th gear bushing has such an oil hole as does the countershaft 5th gear.

4. Be sure that the set rings are in place on the loaded sides of the transmission shafts. Be sure that the dowel pin is in place in the case to locate the counter shaft.

5. Countershaft oil seal must be 40 x 62 x 13.5-2 *only*.

6. When fitting the shafts, be sure that they are properly seated and located by the set rings and dowel pin. Make sure that the oil seal lip is seated in the groove.

7. Check the crankcase oil oriface for a clogged condition before assembly.

The remainder of the procedure is the reverse of disassembly.

Refer to "Crankcase Assembly," above.

AUTOMATIC TRANSMISSION

Transmission Oil Pressure

1. The transmission oil pressure can be checked by means of an oil pressure gauge and gauge fitting (tool No. 07510-3930100). The crankcase is equipped with a pressure gauge fitting on the left side bottom.

2. Park the machine on the center stand and apply the parking brake.

3. Warm the engine until operating temperature is reached. Shut off the engine and connect the pressure gauge.

4. Restart the engine. With the transmission in neutral and the engine idling at 1,500 rpm, oil pressure should be 57–114 psi.

CAUTION: *Do not rev up the engine with the gauge attached.*

5. If the pressure is not within specification, refer to the chart, "Transmission Troubleshooting: Automatic Transmission" in chapter 9.

Stall Speed Test

Before attempting this test, observe the following precautions:

a. Do not let the test last for more than 10 seconds per test.

b. Do not shift gears at any engine speed above idle.

c. No oil pressure gauge must be connected.

d. The engine must be at operating temperature.

1. Park the motorcycle on the center stand with the rear wheel supported firmly off the ground and the parking brake set.

2. Connect a tachometer.

3. When the engine is at operating temperature, shift into low. Open the throttle. The engine should stall out at 2,500–2,900 rpm.

If stall speed is not within this specification, refer to the chart, "Transmission Troubleshooting: Automatic Transmission" in chapter 9.

4. Shift into drive, and repeat the test.

Regulator Valve

The regulator valve should be trouble-free, and removal should not be attempted unless the automatic transmission troubleshooting chart in chapter 9 indicates that a malfunction is probable.

REMOVAL

1. Drain the oil.

2. Remove the oil pan. Remove the oil screen.

3. Unbolt and remove the distribution plate. Unbolt and remove the regulator valve.

INSPECTION

Disassembly of the valve is not possible. Check by substituting a new valve.

INSTALLATION

Installation is the reverse of removal. Use a new drain plug washer, and tighten the drain plug to 25–33 ft. lbs.

Gear Set/Clutches

REMOVAL

1. Remove the engine from the frame. Remove the oil filter case.

2. Remove the side cover components: torque converter, breaker point assembly, left-side case with shifter mechanism, and oil pump.

It is not necessary to disturb the top end components.

3. Remove the upper crankcase bolts; turn the engine over and remove the lower crankcase bolts. Separate the crankcase halves.

4. Lift out the primary shaft and disengage the Hy-Vo drive chain. Lift out the mainshaft and countershaft.

NOTE: *Do not disassemble the transmission shafts unless it is necessary. Gears can be visually inspected in place.*

INSPECTION

1. Check the condition of the gears, noting any wear to the teeth, cracks, or scoring. Replace any damaged gears, and the corresponding gear with which the damaged gear meshes.

2. Check the transmission shafts for scoring or wear.

3. Check the shaft and gear ball and needle bearings. Bearings must be free of discoloration, and must have effortless, quiet movement. For ball bearings, there should be no axial or radial play of the inner race relative to the outer.

If any bearing is worn or damaged, replace the set.

4. Taking care that the friction disc is not damaged in the process, measure the clearance between the clutch end plate and the top friction disc using a feeler gauge blade. If the measured distance is not within 0.5–0.8 mm (0.020–0.032 in.), replace the end plate.

End plates are fitted with a code number which indicates their thickness. New plates are available in six thicknesses according to the following table:

Code No	Thickness (mm/in.)
1	1.8/0.071
2	2.1/0.083
3	2.4/0.095
4	2.7/0.106
no mark	3.0/0.118
6	3.3/0.130

5. Applying compressed air to the oil passage at the back of the clutch, check that the clutch engages, and disengages when the pressure is removed. If it does not, check the clutch piston.

6. To disassemble the clutch, a special tool is necessary to compress the assembly while the snap-ring is removed.

CAUTION: *It is not safe to attempt disassembly without the special tool.*

7. Fit the assembled clutch to the tool and compress the return spring.

8. Remove the small snap-ring. Remove the large snap-ring and separate the clutch components, noting their locations to avoid interchanging the positions of the various parts.

9. Apply compressed air to an oil passage at the rear of the clutch to force out the clutch piston.

10. Check the free length of the clutch return spring. Replace it if shorter than 36.6 mm (1.42 in.). Standard length is 39.7 mm (1.56 in.).

11. Check the thickness of the clutch friction discs and replace them as a set if any is thinner than 1.9 mm (0.075 in.). Standard thickness is 1.95–2.05 mm (0.077–0.081 in.).

12. Check the thickness of the steel plates. Standard thickness and serviceable limits are the same for the friction discs (step 11).

13. Be sure all oil passages are clear. Inspect the check valve for loose rivets.

14. Assembly is the reverse of disassembly. Lubricate the clutch piston before installation and rotate it while pressing down to install it. Be sure the piston is fully seated.

Install the oil seal rings so that their endgaps are 180° apart.

15. If new plates have been fitted, check disc-to-top plate clearance as in step 4.

INSTALLATION

Installation is the reverse of removal. Thoroughly lubricate all parts with motor oil.

Tighten the crankcase mounting bolts in a cross pattern to the proper torque:

8 mm 15–18 ft. lbs.
6 mm 7–10 ft. lbs.

LUBRICATION SYSTEM

CHECKING OIL PRESSURE

1969–78

1. Oil pressure can be checked after removing the oil gallery cap on the right side of the engine and fitting pressure gauge adapter (No. 07510-3000000) and gauge (No. 07506-3000000).

2. At engine operating temperature (oil temperature 140°F/60°C) oil pressure should be 50–64 psi (3.5–4.5 kg/sq cm) at 3,000 rpm.

1979–81

Oil pressure can be checked after removing the oil pressure switch behind the cylinders. Use Honda service tools No. 07506-3000000 (oil pressure gauge) and No. 07510-4220100 (adapter).

Check the pressure when the engine is at operating temperature (about 176°F/80°C). At 7,000 rpm, oil pressure should be 71 psi. If the oil is cold, pressure may be somewhat higher.

ENGINE OIL PUMP SERVICE

1969–78 (Except 750A)

REMOVAL AND INSTALLATION

The oil pump can be removed without removing the engine from the frame. The procedure is as follows:

1. Drain the crankcase oil.
2. Remove the crankcase sump (oil pan).
3. Remove the three oil pump mounting bolts and withdraw the pump.

Installation is in reverse order orf removal. Observe the following points:

a. Use new gaskets and o-rings.

b. Do not forget to install the three oil guide pins and o-rings when installing the pump.

c. Refill the engine with oil.

DISASSEMBLY

1. Remove the three side cover mounting bolts from the oil pump.
2. Remove the left cover (opposite the oil pump drive gear) and remove the inner and outer delivery rotors.
3. Remove the dowel pin from the drive gearshaft and withdraw the shaft.
4. Remove the inner and outer scavenge rotors.
5. Remove the metal oil strainer from the bottom of the pump. Remove the four bolts at the pump base and separate the rotor housing from the pump body.
6. Remove the check valve cap bolts and remove the cap. Withdraw the check valve and spring.
7. Unscrew the oil pressure relief valve cap and withdraw the valve and spring.

INSPECTION

1. Clean the oil strainer in solvent and replace it if damaged in any way.
2. Examine the side covers, rotor housing, and pump body for damage and stress cracks.
3. Assemble each outer rotor, in turn, into the housing and measure the clearance between the rotor and housing. Clearance should not exceed 0.35 mm (0.014 in.).
4. Install each inner rotor, in turn, into its matching outer rotor and measure clearance between the inner rotor tips and the outer rotor, as illustrated. Clearance should not exceed 0.35 mm (0.014 in.).
5. If the clearance limit is exceeded in steps 3 or 4 above, the housing and rotors should be measured for wear and should be replaced as necessary. Rotors should be replaced in sets (inner and outer) only.
6. Measure the diameter of the check valve and check valve cylinder bore. Measurements should be within the limits given in the "Oil Pump Specifications" chart at the end of this chapter. The calculated clearance between the valve and bore should not exceed 0.17 mm (0.0067 in.). Replace the valve and/or oil pump body if worn beyond specification.
7. Check the oil pressure relief valve and bore in the same manner as above (step 6). Calculated clearance should not exceed 0.10 mm (0.0039 in.).
8. Check rotor end-play by measuring the thickness of each outer rotor, in turn, and subtracting this from the measured depth of the corresponding rotor housing. Calculated endplay at either side of the pump should not exceed 0.12 mm (0.0047 in.). Replace the rotor housing or rotors as necessary (refer to "Oil Pump Specifications").

ASSEMBLY

Assembly is in reverse order of disassembly. The following points should be noted:

a. Oil pump rotors are fitted with punch marks and should be installed so that both punch marks face the same direction.

b. Do not reuse old o-rings.

c. Lubricate all moving parts with fresh oil before installing.

d. Be sure that the drive pins are securely installed in the drive gearshaft.

e. After the pump is assembled, turn the drive gear by hand to make sure that the pump operates smoothly.

f. Before installing the pump in the crankcase, immerse it in oil and turn the drive gear until the pump is filled.

750A

REMOVAL AND INSTALLATION

The oil pump can be removed without removing the engine from the frame.

1. Drain the oil.
2. Remove the gearshift lever, kick-start rubber, and left-side footpeg.
3. Remove the rear portion of the left-side crankcase cover. Have a drip pan ready beneath the cover to catch any oil residue.
4. Remove the left side case. Unbolt and remove the oil pump.

The oil distribution plate and regulator valve, as well as the filter screen, are accessible after the oil pan is removed. Refer to chapter 4.

Installation is the reverse of removal. Note the following points:

a. Use a new case gasket.

b. Be sure the pump internals are thoroughly lubricated before installation.

c. Tighten the oil pump bolts securely.

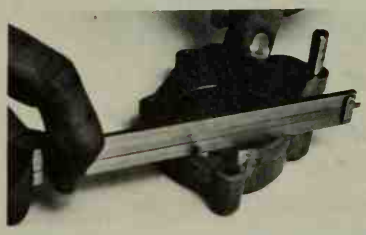
DISASSEMBLY

1. Remove the two bolts which hold the oil pump cases together and separate the case halves, removing the pump cover. Remove the pump body after taking out the shaft pin.
2. Remove the inner rotor, outer rotor, and the remaining pump shaft pin. Withdraw the shaft.

INSPECTION

1. Clean all components thoroughly.

Check the clearances for both sets of rotors as follows:



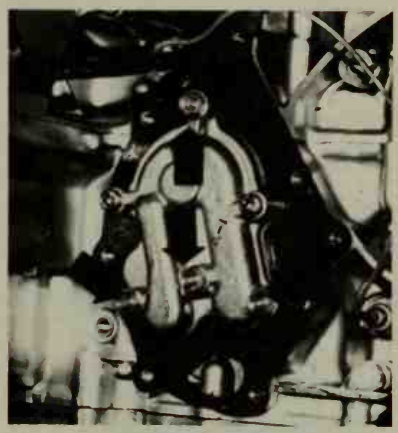
2. Measure the clearance between the outer rotor and the oil pump body. It should be 0.15–0.22 mm (0.0059–0.0087 in.). Replace the pump if clearance is over 0.35 mm (0.0138 in.).
3. Measure the clearance between the tips of the inner rotor and the outer rotor. The standard value is 0.15 mm (0.0059 in.). Replace the pump if clearance exceeds 0.20 mm (0.0079 in.).
4. Place a straightedge across the rotors and body and measure the clearance between the rotor surface and the straightedge. Standard clearance is 0.02–0.06 mm (0.0008–0.0024 in.). Replace the pump if the clearance is more than 0.08 mm (0.0031 in.).

Measuring clearance between the outer rotor and the pump body

Measuring inner rotor to outer rotor clearance

Checking clearance between the rotors and the pump body

ASSEMBLY



Assembly is the reverse of disassembly. Be sure the internals are well lubricated.

Oil pump rotors are fitted with punch marks and they should be installed so that both marks face the same direction.

1979–81

REMOVAL AND INSTALLATION

It is possible to remove the oil pump without removing the engine from the frame.

Oil pump mounting bolts (arrows)

1. Remove the rider footpegs. Remove the gearshift lever.
2. Remove the left rear crankcase cover.
3. Remove the oil pump cover (6 bolts).
4. Remove the oil pump by removing the 4 bolts (do not remove the phillips screws at this point).
5. Installation is the reverse of removal. Lubricate the pump internals by filling it with motor oil. Use a new pump gasket. When installing the pump, engage the gears carefully. Be sure that the dowel pin in the lower right-hand corner is fitted.
6. After the pump cover is installed, be sure that the neutral switch wire is properly arranged and secured with its clamp.

DISASSEMBLY

1. Remove the two phillips screws which secure the pump body cover.
2. Remove the inner and outer rotors. Remove the drive pin and shaft.

NOTE: *The rotors are punch-marked to indicate position. Note the direction of the punch marks, and be sure that the rotors are installed the same way they came out.*

INSPECTION

1. Clean all parts thoroughly.
2. Measure the clearance between the inner and outer rotors. Clearance should not exceed 0.15 mm (0.006 in.) on 750 models or 0.20 mm (0.008 in.) for 900s. If the measurements exceed these service limits, replace the rotors.
3. Check the clearance between the outer rotor and the pump body. If clearance exceeds 0.35 mm (0.014 in.), either the pump body or the rotors will have to be replaced. This specification applies to both 750 and 900 models.

Measuring outer rotor to body clearance

4. Place a straightedge across the pump body and rotors and measure the rotor-to-housing clearance by attempting to slip a feeler gauge blade between the straightedge and the rotors. If clearance exceeds 0.1 mm (0.004 in.), replace the rotors or the pump body.

NOTE: *The rotors are always replaced in sets.*

ASSEMBLY

1. Clean all parts thoroughly, and lubricate the internal parts with clean motor oil.
2. Install the outer rotor into the pump body. Note the position of the rotor punch mark.
3. Install the drive shaft.
4. Insert the pin into the drive shaft.
5. Install the inner rotor, aligning the slots in the rotor with the pin on the drive shaft.
6. Fit the body cover. Tighten the screws securely.

SUBTRANSMISSION OIL PUMP

Removal

1. Remove the rider footpegs.
2. Remove the exhaust pipe heat shield. Remove the selector lever and the selector arm.
3. Drain the subtransmission oil.
4. Remove the cover.
5. Remove the shift drum.
6. Remove the o-ring.
7. Heat the case gently and evenly in the area around the bearing. Tap the bearing out with a plastic mallet.
8. Remove the circlip and take out the oil pump assembly.

Inspection

1. Clean the filter screen in place with compressed air.

NOTE: *Do not attempt removal of the filter screen.*

2. Clean all parts in clean motor oil.

3. Check bearing rotation in the usual manner.

Installation

1. Lubricate all parts with clean motor oil. Be sure that the components are free of foreign matter.

2. Install the pump assembly, aligning the oil pump boss with the cover groove.

3. Install the circlip. Drive the bearing into place.

4. Lubricate the bearing with fresh SAE 80 oil.

5. Install the shaft drum.

6. Turn the rear wheel or drive gear by hand so that the slot in the drive gear shaft collar is vertical. Install the case cover with the oil pump drive shaft boss aligned with the collar slot and new o-ring.

CAUTION: *The cover must be installed carefully and without the use of force. If installation is not easy, check the location of the shift drum and shift fork.*

7. Tighten the cover bolts to 22–25 ft. lbs.

FUEL SYSTEM

NOTE: *For carburetor theory and operational description, refer to the "General Information" section.*

CARBURETORS

CB750 Pre-K1

NOTE: *The procedure described below applies to the early carburetor assembly with four short individual cables controlling the throttle slides*

REMOVAL AND INSTALLATION

1. Remove the fuel tank. Drain the carburetor float.

2. Unscrew the cap from the top of each carburetor and carefully withdraw the slides.

3. Loosen the air filter connecting clamp at each carburetor and remove the air filter housing so that the carburetors can be moved back.

4. Loosen the carburetor-to-intake tube mounting clamps and remove the carburetors as a unit.

Installation is in reverse order of removal. The following points should be noted:

a. Make sure that the carburetors are securely clamped to the intake tubes. If necessary, replace the clamps.

b. When reinstalling the slides in the carburetors, take special care not to damage the needles when dropping them into the jet tubes. The tab in the slide bore must engage the slot in the slide. Tighten the caps firmly by hand after the slides have been installed.

c. Check carburetor adjustment and synchronization after installation. Check for smooth throttle operation.

DISASSEMBLY

NOTE: *Disassembly procedure is given for one carburetor but applies to all four. Keep each carburetor and its components separate from the others; do not interchange parts between carburetors.*

1. Disconnect the carburetor slide from the throttle cable by compressing the spring and feeding the inner cable into the slide so that the cable end can be disengaged from the retaining slot.

2. Disconnect the choke linkage and remove the screws holding the carburetors to the mounting plate. Remove all four carburetors and separate them. Do not misplace the connecting tube.

3. Release the float bowl by swiveling back the retaining clip.

4. Tap out the float hinge pin using a small diameter rod or drift. Remove the float and lift the float needle out of the valve seat. Unscrew the seat from the carburetor body.

5. Using a small screwdriver, remove the main jet, pilot jet, and pilot air screw. The main jet and jet holder can be taken out as one piece if desired.

6. Unscrew the main jet holder is not already removed.

CLEANING

Clean all metal parts in a solvent or carburetor cleaner which is safe for plastic parts. Use compressed air to dry parts. Blow all fuel jets clear. Never insert anything into the jet bores to clear them if clogged.

ASSEMBLY

Assembly is the reverse of the disassembly procedure. The following points should be noted:

a. Use new gaskets and o-rings.

b. The float should be positioned so that when the float arm just touches the tip of the float needle, the distance from the top of the float to the float bowl mating surface on the carburetor is 26 mm (1.02 in.). Bend the float arm in the desired direction if adjustment is necessary.

NOTE: *A special float level gauge (part No. 07144-99998) is available from Honda dealers.*

c. Do not overtighten the jets when installing them in the carburetor body.

d. Make sure that the jet needle is installed in the same position as when removed. Changing needle position in the slide will affect running at mid-range throttle openings.

e. Check for smooth operation of the chokes after the linkage has been connected. If a clearance greater than 0.5 mm (0.02 in.) exists between the choke valve and throttle bore with the choke fully

Oil Pump Specifications

1969–1978 (Except 750A)

	Standard (mm/in.)	Serviceable Limit (mm/in.)
Rotor housing diameter	40.65–40.68/1.600–1.602	40.85/1.608
Rotor housing depth		
Delivery side	18.02–18.04/0.7095–0.7102	18.07/0.711
Scavenge side	12.02–12.04/0.4732–0.4740	12.07/0.474
Rotor diameter	40.53–40.56/1.589–1.600	40.50/1.595
Rotor thickness		
Delivery side	17.98–18.00/0.7079–0.7087	17.95/0.707
Scavenge side	11.98–12.00/0.4717–0.4724	11.95/0.471
Check valve diameter	17.93–17.95/0.7059–0.7067	17.91/0.705
Check valve cylinder bore	18.00–18.03/0.7087–0.7097	18.08/0.712
Relief valve diameter	11.957–11.984/0.4707–0.4718	11.93/0.450
Relief valve cylinder bore	11.973–12.000/0.4714–0.4724	12.03/0.474
Rotor tip clearance	—	0.35/0.014
Rotor-to-housing clearance	—	0.35/0.014

750A

Outer rotor-to-body clearance	0.15–0.22/0.0059–0.0087	0.35/0.0138
Rotor tip clearance	0.15/0.0059	0.20/0.0079
Rotor-surface-to-body clearance	0.02–0.06/0.0008–0.0024	0.08/0.0031
Relief-valve-to-body clearance	0.025–0.070/0.001–0.0028	0.1/0.004

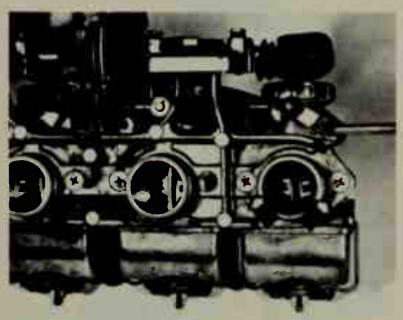
750, 1979–1981

Outer rotor-to-body clearance	—	0.35/0.0138
Rotor tip clearance	—	0.15/0.006
Rotor surface-to-body clearance	—	0.1/0.004

900

Outer rotor-to-body clearance	0.15–0.22/0.059–0.087	0.35/0.014
Rotor tip clearance	0.15/0.059	0.20/0.008
Rotor surface-to-body clearance	0.02–0.07/0.008–0.028	0.10/0.004

closed, the adjusting rod should be lengthened or shortened as required.



NOTE: *The carburetors on the CB 750 (pre-K1 models) were modified during the production run, and all early models without the modifications are entitled to have this update performed by the dealer, regardless of whether or not the maching is out of warranty or was purchased used. An examination of the caps will reveal whether or not the carburetors incorporate the modifications. The original caps are 11.5 mm (0.45 in.) high and the modified caps are 14.5 mm (0.57 in.) high.*

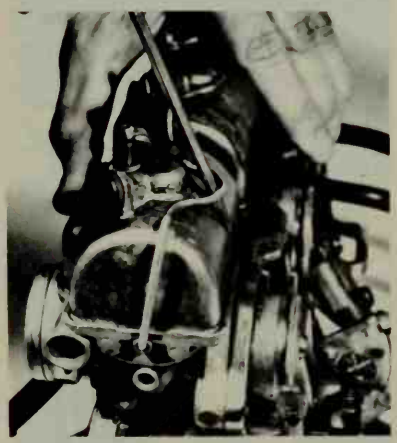
CB750K1-K5, CB750 (1976), CB750F (1975-76)

REMOVAL AND INSTALLATION

Carburetors should be removed as an entire assembly.

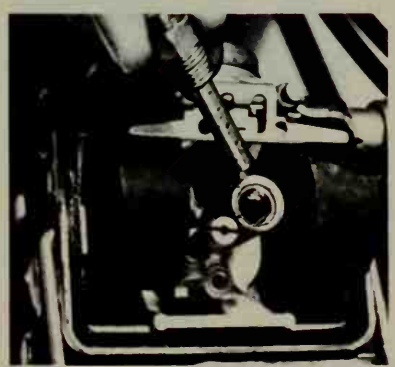
1. Remove the gas tank. Remove the side covers. Remove the air cleaner box. Drain the gas from the float bowls.
2. Disconnect the overflow lines from the carburetors.
3. Disengage the carburetor cables from the pulley and the adjusters from their holders.
4. Loosen the carburetor manifold screws.
5. Pull off the carburetors.

To remove the carburetors, disconnect the choke linkage and remove the two phillips screws (arrows)



Back off the throttle rod nuts to disengage the carburetor from the linkage

6. To remove individual carburetors, disconnect the return springs, and remove the cotter pin which secures the choke linkage pin.
7. Fold back the rubber boot on the carburetor top. Back off the adjuster nuts. Remove the two phillips screws at the carburetor fold.



Installation is the reverse of removal. Synchronization of the carburetors is necessary.

DISASSEMBLY

1. Unscrew and remove the carburetor cap and take out the slide assembly. To remove the needle, take out the two small phillips screws inside the carburetor slide.
2. Flip back the float bowl retaining clip. Remove the float bowl.
3. Unscrew and remove the main jet holder with the main jet. Unscrew and remove the pilot jet.
4. Push out the float pivot pin and remove the float bulbs.
5. Remove the float needle.
6. Unscrew and remove the needle seat.
7. Turn the carburetor over and take out the needle jet, pushing it out from the top if necessary.
8. Unscrew and remove the pilot screw.

Removing the float bowl

Removing the main jet and holder

CLEANING

Since the carburetor may have inserted plastic parts, use only a parts cleaner which will not harm plastic.

Use compressed air to dry the parts. Blow all fuel and air passages clear. Never insert anything into jet bores to clear them if they are clogged.

Removing the floats

ASSEMBLY

Assembly is the reverse of the disassembly procedure. The following points should be noted:

1. Use new gaskets and o-rings.
2. The float should be positioned so that when the float arm just touches the tip of the float needle, the distance from the top of the float to the float bowl mating surface on the carburetor is 26.0 mm (1.02 in.). Bend the float arm in the desired direction if adjustment is necessary.

NOTE: *A special float level gauge (part No. 07144-99998) is available from Honda dealers.*

3. Do not overtighten the jets when installing them in the carburetor body.
4. Make sure that the jet needle is installed in the same position as when removed. Changing needle position in the slide will affect running at mid-range throttle openings.
5. Check for smooth operation of the chokes after the linkage has been connected. If a clearance greater than 0.5 mm (0.02 in.) exists between the choke valve and throttle bore with the choke fully closed, the adjusting rod should be lengthened or shortened as required.

CB750A, CB750K (77), CB750F (77)

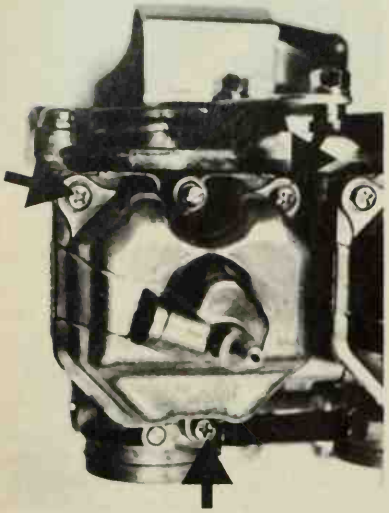
REMOVAL AND INSTALLATION

Carburetors must be removed as an entire assembly.

1. Remove the gas tank. Remove the side covers. Remove the air cleaner box. Drain the float bowls.
2. Disconnect the overflow lines from the carburetors.
3. Disengage the carburetor cables from the pulley and the adjusters from their holders.
4. Loosen the carburetor manifold screws.
5. Pull off the carburetors.

Installation is the reverse of removal.

DISASSEMBLY



1. Remove the float bowl screws and take off the float bowl.
2. Unscrew and remove the main jet, jet holder, and pilot jet.

3. Push out the float pivot pin and remove the float bulbs to which the float needle is attached.

4. Remove the needle jet.

5. To disassemble the carburetors completely, remove the two screws which secure the choke plate at each carburetor mouth.

6. Remove the top from each carburetor. Remove the brace which holds them together. Remove the shaft securing screw

Float bowl securing screws (arrows)

(accessible after removing the tops). Disconnect the balance tubes. Slide the carburetors off the throttle shaft.

CLEANING

Clean the carburetor in a solvent which is safe for plastic parts.

Use compressed air to blow parts dry. Blow all air and fuel passages clear. Never insert anything into the jet bores to clear them if clogged.

ASSEMBLY

Assembly is the reverse of disassembly. Float level is 14.5 mm (0.571 in.).

CB750K,F,C (1979–81) and CB900

REMOVAL AND INSTALLATION

NOTE: *The carburetors must be removed as an assembly.*

1. Turn the petcock "off," disconnect the fuel line at the carburetor.

2. Remove the left and right side covers.

3. Loosen the air cleaner clamps. Move the air cleaner as far as possible to the rear.

4. Loosen the carburetor manifold clamps. Remove the carburetors as an assembly. Disconnect the choke and throttle cables.

CAUTION: *Remember that the carburetors are full of gasoline. Drain the float bowls into a suitable container by loosening the drain screws.*

5. Installation is the reverse of removal. Note the following points:

a. Do not interchange the "pull" and "push" throttle cables. The "pull" cable is closest to the engine.

b. Be sure that the carburetors are firmly seated in the manifold spigots.

c. Be sure that the air cleaner tubes are not twisted or folded up so as to block the carburetor intakes.

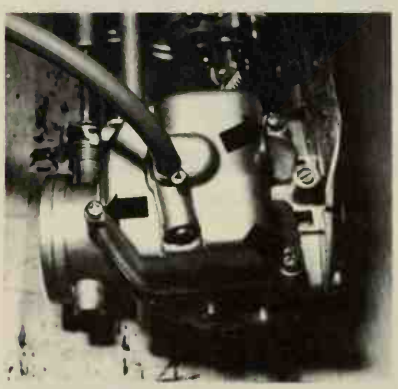
d. Adjust the throttle cables, butterfly synchronization, idle and fast idle adjustments.

e. Be sure that all fuel line connections are tight and secured with the safety clips. Before operation, turn on the fuel and check for leaks.

DISASSEMBLY

1. Loosen the locknut, and back off the butterfly synchronization screw.

NOTE: *The slides will have to be synchronized after assembly.*



2. Disconnect the spring from the choke lever.

3. Remove the phillips head screws and take off the rear and the front stays.

4. Separate the carburetors, noting that

Removing the cap and spring

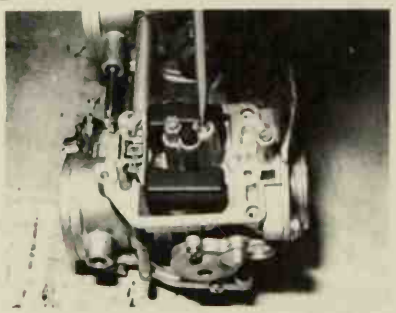
Float bowl screws (arrows)

the fuel connecting pipe and the choke spring will come loose. The pipe has o-rings on both sides. Do not lose them.

From this point, disassembly is given for one carburetor, but applies to both.

5. Unscrew and remove the carburetor tops. Take out the spring, and the throttle slide assembly with jet needle.

The jet needle can be removed from the throttle slide after taking off the full open stopper and unscrewing the needle set screw.

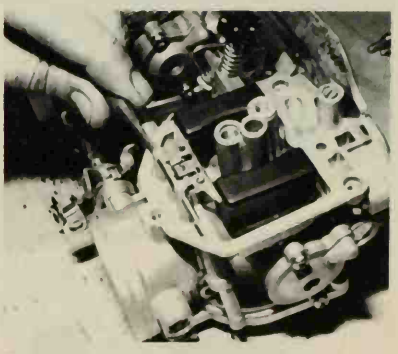


6. Remove the seal ring from the top of the carburetor body.

7. Remove the air jet cover.

8. Remove the float bowl screws, and very carefully take off the float bowl.

9. Unscrew and remove the primary and secondary main jets.



10. Remove the slow jet plug.

Removing the secondary main jet

Removing the needle jet

Pushing out the float pivot pin

NOTE: *The slow jet itself is a press-fit in the carburetor body and cannot be removed.*

11. Remove the primary nozzle which is beneath the primary main jet.

12. Remove the needle jet holder.

13. Unscrew and remove the pilot screw. Note that the pilot screw will have to be adjusted during reassembly. Note the spring and o-ring on the jet.

14. Use a needle-nosed pliers to pull out the float pin. Remove the floats. Remove the float needle.

15. Remove the air cut-off valve cover and take out the spring. Remove the diaphragm very carefully and take out the o-ring as well.

ASSEMBLY

Assembly is basically the reverse of the disassembly procedure. Note the following points:

1. Always use new gaskets and O-rings.
2. Exercise care when installing jets—they are made of soft brass and are easily damaged if overtightened.
3. Be sure that the float pivot pin is properly seated, and that the floats pivot freely.
4. Tighten the float bowl screws slowly and evenly. Be sure that the O-ring is seated in its groove before installing the float bowl.
5. When installing the pilot screw, place the o-ring and the spring on the screw, then turn it in very carefully until it is seated. Then back the screw off the number of turns indicated in the "Carburetor Specifications" chart.
6. When joining the two carburetors together, be sure that the o-rings are in place on either end of the fuel pipe. Fit the pipe into the carbs carefully to avoid damage to the o-rings.
7. Do not forget the choke relief spring.

Carburetor Separation

Although almost all routine work can be performed with the carburetors attached together, the units may have to come apart. If this is desired, proceed as follows:

1. Unhook the choke relief spring from the shaft arm between carburetors Nos. 3 and 4.
2. Loosen the synchronization screw locknuts. Turn the synchronization screws in until they seat and note the number of turns so that they can be roughly repositioned when assembling. Then back the screws out until there is no tension.
3. Remove the rear bracket which is held to each carburetor by two screws.
4. Remove the front bracket.
5. Separate the carburetors between units Nos. 2 and 4. Pull them straight apart to avoid damage to the lines.
6. File the staked ends of the choke valve screws. Remove the screws. They must be replaced with new ones on assembly.
7. Remove the fuel line holder from the No. 1 carb. Separate the carbs. Be careful to pull them straight apart to avoid damage to the fuel and air lines.
8. After noting the spring position, remove the choke relief spring from the choke linkage. Remove the choke shaft.

NOTE: *The choke shaft, valves, and screws cannot be reused.*

9. Remove the cotter pin from the accelerator pump rod. Remove the plain washers, spring and collar.
10. Remove the fast idle adjusting arm bolt.
11. Remove the fast idle adjusting arm and springs.
12. Remove the accelerator pump rod. Drive out the throttle linkage retaining pin. Remove the throttle linkage.
13. Assembly is basically the reverse of disassembly. Note the following points:

a. assemble one pair of carbs at a time;
b. use new o-rings on the fuel line joints;
c. lubricate the o-rings with a bit of grease before assembly;
d. install the fuel line, accelerator pump joint and air vent pipes on the No. 3 unit. Install the choke dust tube. Loosen the synchronization adjusting screw until there is no tension. Insert the No. 3 unit throttle link between the plain washers. Assemble carburetors Nos. 3 and 4.

NOTE: *The large washer should be positioned on the spring side.*

e. assemble carburetors Nos. 1 and 2 in the same manner;
f. insert new choke shafts and assemble the linkage;
g. install the front bracket screws, but do not tighten them;
h. place the carbs on a flat surface with the float bowls facing up. Press them together and tighten the screws evenly by tightening the left side screw on each carburetor first, then going back and securing the right side screw on each one. Tighten the screws gradually to 3–4 ft. lbs.

NOTE: *After securing the screws, check for smooth choke shaft operation. Recheck alignment if operation is not satisfactory.*

i. fit the rear bracket using the same procedure. Tighten the rear bracket screws to 2–3 ft. lbs.
j. install the thrust springs between No. 1 and 2 and between Nos. 3 and 4 throttle linkages;
k. turn each synchronization adjusting screw to its original position as noted during disassembly;
l. adjust the throttles so that the distance between the by-pass hole and the throttle plate is the same for each unit;
m. open the throttle slightly, then release. Be sure that the throttle linkage is smooth and free of binding;
n. hook the choke relief spring to the choke shaft between units 3 and 4. Install the choke valves, but do not tighten the screws; be sure that choke valve operation is smooth, then tighten the valve screws to 5–11 ft. lbs. Fold the tabs on the lockwasher up. Recheck choke and throttle operation.

FUEL PETCOCK

Removal, Cleaning, and Inspection

1974 AND EARLIER MODELS

1. Turn the petcock lever to "stop" and disconnect the fuel lines.
2. Raise the seat, and raise and support the rear of the gas tank.
3. Unscrew the sediment bowl from the petcock, being careful of the gasoline which will also spill out.
4. Remove the o-ring and filter.
5. Remove the two screws which secure the petcock body to the gas tank, and remove the petcock.
6. Clean all components in gasoline and dry; then inspect for damage.
7. When assembling the petcock, it is advisable to use new gaskets and o-rings.
8. After installing the petcock, check for proper gas flow as well as leaks.

1975 AND LATER MODELS

The petcock filter screen is inside the gas tank.

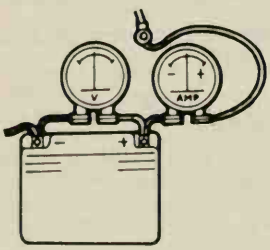
1. Disconnect the fuel lines from the petcock. Remove the tank from the machine, and drain off the gas.

2. Unscrew the securing nut and carefully take out the petcock. Remove the securing nut and filter from the petcock.

3. Wash the filter in a solvent. Replace the filter if it is punctured or badly clogged. Check the condition of the gasket and replace it if it is crushed or nicked.

Installation is the reverse of removal. Be sure that the fuel lines are secured to the petcock with the safety clips. Check for leaks before operating the motorcycle.

ELECTRICAL SYSTEM



CHARGING SYSTEM, 1969–78

Alternator Output Test

1. Check the state of charge of the battery. If battery voltage is less than 12 volts, or if specific gravity of the electrolyte is less than 1.260 (fully charged), recharge the battery before proceeding with the test.

2. The test is performed using an ammeter and a voltmeter. Connect the ammeter as follows: disconnect the positive (+) battery cable and connect it to the positive side of the ammeter; connect the negative (−) side of the ammeter to the positive battery terminal. Connect the voltmeter as follows: connect the positive side of the ammeter to the positive battery cable, and ground the negative voltmeter lead on the engine.

3. Start the engine and check the amperage and voltage output of the alternator under both day riding (lights off) and night riding (lights on) conditions, assuming it is possible to shut off the headlight on your model. If the readings obtained are noticeably greater or smaller than those in the accompanying table, adjust the regulator. Slight variation is acceptable due to the effect of the state of charge of the battery upon alternator output. If alternator output is satisfactory but the battery has discharged during use, refer to the section on testing the rectifier.

Alternator output set-up

Regulator Adjustment

1. Disconnect the three wires at the regulator, marking them so that they can be replaced on the same terminals. Take out the two mounting bolts and remove the regulator unit.

2. Remove the two screws and take off the regulator cover.

3. Examine the condition of both sets of contact points. If dirty or pitted, they may be cleaned up with fine emery paper.

4. Measure the core gap with a feeler gauge. If the gap does not measure within 0.6–1.0 mm (0.024–0.040 in.), loosen the core gap adjusting screw and move the point body up or down as required.

5. Measure the gap of the upper point set in the same manner. The points should be gapped at 0.3–0.4 mm (0.012–0.016 in.). To adjust the gap, loosen the adjusting screw and move the lower contact up or down as required.

6. Temporarily install the regulator with one of the mounting bolts, leaving the cover off. Connect the three wires.

7. Loosen the voltage adjusting screw locknut. If the alternator output test showed insufficient output, turn the voltage adjusting screw clockwise about ¼ turn. If the test showed output to be excessive, turn the screw counterclockwise about ¼ turn. Tighten the locknut and rerun the alternator output test. Readjust the screw as necessary to obtain satisfactory alternator output.

8. If alternator output is unstable or excessive after the regulator has been adjusted properly, chances are that the regulator is faulty. If alternator output is insufficient and cannot be brought up to specification through regulator adjustment, the alternator itself should be suspected. Before proceeding any further, make sure that the battery is producing at least 12 volts at the terminals, and that none of the cells are dead or have a noticeably lower specific gravity than the rest. If the battery checks out alright, replace the regulator or check into the alternator (refer to the "Alternator Service" section), as indicated.

Testing the Rectifier

If alternator output is satisfactory but the battery discharges as the engine is running, it is quite possible that the rectifier is not functioning properly. (This is assuming, of course, that the battery is not old and tired or has one or more bad cells.) Before removing and testing the rectifier, make sure that it is solidly mounted on the frame. The rectifier is grounded through its mounting and will not operate without a good ground.

CAUTION: *Do not loosen or tighten the nut that holds the rectifier unit together, as this will adversely affect operation of the rectifier.*

1. To test the rectifier, first pull apart the plastic connector, unscrew the mounting nut, and remove the rectifier unit. Inside the rectifier are six diodes which, if functioning properly, will allow electricity to pass in only one direction.

2. Check the diodes, using either a multimeter or a test light and the motorcycle battery. If the test light and battery are to be used, simply run a length of wire off one of the battery terminals and connect one of the test light leads to the other terminal. The two free wire ends will be used to check electrical continuity of the diodes.

3. Connect one of the leads to pin green in the connector block and touch the other lead to each yellow lead in turn. Now, reverse the leads and repeat the procedure. The test light should light (or the meter needle respond) in one direction only.

4. If all is well so far, connect one of the leads to red/white and touch the other to each yellow again. Reverse the leads, as before, and repeat.

5. Continuity in both directions or in neither direction (when reversing the leads) indicates a defective diode, in which case the rectifier unit must be replaced.

NOTE: *On an ohmmeter, "continuity" will be indicated by a resistance of 5–40 ohms. "No continuity," by a resistance of 2000 or more ohms.*

The diodes are quite susceptible to failure from excessive heat and electrical overload. Observe the following precautions to avoid rectifier failure:

a. Do not use high-voltage test equipment to test the rectifier diodes.

b. Do not run the engine at high rpm with the rectifier "P" terminal disconnected, or else the high voltage that is produced will damage the rectifier.

c. Do not quick-change the battery (high-output charging equipment) without first disconnecting one of the battery cables.

Rectifier connector

Alternator Output

Engine rpm	*1000*	*2000*	*3000*	*4000*	*5000*	*6000*	*7000*	*8000*
Day riding (headlight off)	6.5	0	2.4	1.3	1.0	1.0	0.8	0.6
Night riding (headlight on)	2–3	1	1	1	1	1	1	1
Battery terminal voltage	12	12.4	13.2	14.5	14.5	14.5	14.5	14.5

Alternator Service

Removing the alternator cover will allow access to the alternator components for testing purposes.

The field coil and the alternator stator will remain in the cover. To remove the stator, remove the four screws inside the cover. To take out the field coil, remove the three screws visible on the outside of the cover.

FIELD COIL

1. Check for continuity between each field coil lead and the core, using an ohmmeter or test light. If there is continuity between the leads and core, the coil is grounded and must be replaced.
2. Check for continuity between the two leads themselves. Continuity must exist or the coil is open and must be replaced.

Resistance of the field coil should be on the order of 7.2 ohms for 5-speed models, and 4.1 ohms for the 750A. If significantly less than this (within 10%), replace the coil.

Alternator field coil (white arrow) and stator (black arrow)

STATOR COIL

1. Check for continuity between pairs of yellow stator coil leads. Continuity must exist in all cases. If there is an open circuit, the stator must be replaced.
2. Check the resistance of the stator coils (between yellow leads). It should be about 0.2 ohms for 5-speed models, and 0.48 ohms for the 750A.
3. Check for continuity between each coil lead and the coil body. There must be none, or replacement is in order.

ROTOR

The rotor can be left in place unless replacement is necessary.

NOTE: *On some 750s, the rotor has a tendency to slip on the crankshaft taper as the engine is running, decreasing alternator output and causing the battery to discharge. To prevent this, the crankshaft and rotor tapers must be absolutely clean and smooth before installing the rotor, and the retaining nut must be tightened to specification. If the slipping persists, apply a thin layer of valve lapping compound to the crankshaft taper and install the rotor over it. This will lock the rotor firmly on the crankshaft after the retaining nut is tightened.*

CHARGING SYSTEM, 1979–1981

Alternator Output Test

Refer to the alternator output test procedures given for earlier models, above.

With the headlight on "high beam," initial battery charging should begin at 1,700 rpm.

At 5,000 rpm, there should be a minimum of 8 amps/14.0 volts.

If readings are not satisfactory, check the alternator circuits as described below, and the regulator/rectifier unit. Unlike the previous system, the regulator is not adjustable.

Testing the Rectifier

Refer to "Testing the Rectifier" for the earlier models, above. Procedures and results should be the same. Be sure to observe all of the appropriate cautions.

Testing the Regulator

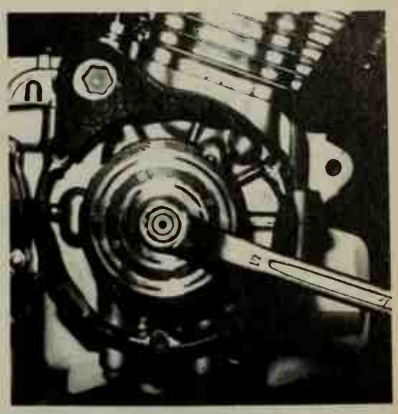
A check of the voltage regulator can be carried out if the alternator does not keep the battery charged. The regulator, however, cannot be adjusted. If defective, it must be replaced.

1. Connect a DC voltmeter across the battery. Start the engine and run it up to about 2,000 rpm.
2. Battery voltage should be in the neighborhood of 14–15 volts.

NOTE: *The battery must be in good condition and fully charged to ensure an accurate reading.*

3. If the reading is not satisfactory, proceed as follows.
4. Connect two 12-v motorcycle batteries in series (positive to negative terminals). Be sure that they are in good condition and fully charged.
5. Connect a variable resistor, capable of at least 100 ohms across the batteries with a 50 ohm resistor between. Connect a DC voltmeter across the batteries.
6. Connect the battery leads to the green and the black regulator leads at the 4-p connector. Apply a test light to the black and the white regulator leads at the 6-p connector. Adjust the variable resistor until the voltmeter reads 14–15 volts. At this point, the test light should go out.

If the test light does not go out, or if it will not light at all, replace the regulator.



Alternator Service

Removing the alternator cover will allow access to the alternator components for testing purposes.

The alternator stator and the brush holder will remain in the cover. To remove them, remove the two brush holder screws and the three stator coil screws.

ROTOR

1. Clean the rotor with a rag to remove any metal particles or foreign matter. To remove the rotor, place the transmission in gear and apply the rear brake. Remove the rotor bolt. Remove the rotor with the special puller.
2. When installing the rotor, first be sure that the crankshaft taper is clean. Push the rotor on by hand. Do not hammer it on or strike it.
3. Tighten the rotor bolt to 58–72 ft. lbs.

Removing the alternator rotor bolt

BRUSHES

1. Replace the alternator brushes when they are worn to the scribed limit line.
2. Clean the brushes with a bit of gasoline if they are dirty.
3. Clean the brush tracks on the rotor in the same manner.

Check brush length. Limit line is marked on the brushes

STATOR COILS

1. Check for continuity between pairs of the yellow stator coil wires. Continuity must exist in all cases. If there is an open circuit, the stator must be replaced.
2. Check the resistance of the stator coils (across pairs of yellow wires). Resistance should be 0.41–0.51 ohms in each case. If the resistance is too high or too low, replace the stator.
3. Check for continuity between each yellow lead and the stator body. There must be none, or replacement is in order.
4. Resistance between the black and white terminals should be 10–12 ohms.

FIELD COIL

The field coil is within the rotor. There should be 3.6–4.4 ohms restance between the brush tracks on the rotor. If resistance is very high, replace the rotor.

IGNITION SYSTEM, 1969–78

The ignition system consists of the battery, breaker points, coils, condensers, spark plug caps, and spark plugs.

There are two sets of breaker points and two ignition coils. Each coil fires two cylinders. They are paired No. 1 and 4, and No. 2 and 3.

1. In the event of failure of the ignition system, first check the fuses, if all are in working order, check that the snap connectors for the coils and breaker points are all clean and tight.

Checking spark plug cap resistance

2. Inspect the breaker points, plugs, and battery. If these items are all in working order, the problem may be isolated to the coils, condensers, or plug caps.

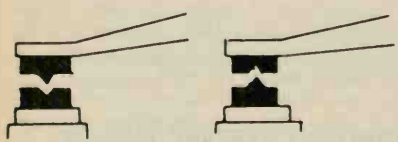
3. If only one cylinder fails to fire, and the problem is not a loose connection or defective spark plug, suspect the plug cap. The caps are fitted with a resistor to prevent radio interference while in operation, and heat and vibration may cause the value of this resistor to increase considerably, even to becoming an open circuit.

The easiest way to see if a misfire is due to a defective cap is to switch the plug lead of the non-firing cylinder with its corresponding cylinder (1–4, 2–3). If the dead cylinder begins to fire and the other cylinder ceases, the problem is the plug cap. The caps should be replaced as a set.

Functional caps will have a resistance of 5,000–7,500 ohms. Usually, when resistance reaches about 9,000 ohms, the plug for that cap will no longer fire.

Caps are easily removable by unscrewing them from their cables.

4. Defective condensers are seldom a problem, since these are now usually replaced along with the breaker points. Defective condensers will cause considerable arcing or sparking between the breaker point contacts while the machine is running, and this should be cause for replacement before they fail completely. Badly burned or pitted point contact surfaces can also be caused by defective condensers, as well as by improper adjustment. If the points are in bad condition, replace them and the condensers as well.



5. Condenser capacity can be checked with electrical test equipment (if available) in place on the machine, provided the condenser is first disconnected from the primary terminal. Capacitance should be 0.24 MFD. The resistance of the condensers should be in excess of 10 MΩ. A variation of 10% in either reading is allowable.

6. If the condensers are not suspect, check the ignition coils. Coils should be checked for continuity of the windings. First disconnect the blue and the black/white leads from the left coil and check for continuity between these leads. If there is none, the coil must be replaced.

For the other coil, carry out the same test between the yellow and the black/white leads.

Check for continuity on the high-tension side of each coil. Disconnect the two spark plug leads of one of the coils and check the continuity between them. If none exists, replace the coil. Repeat the test with the other coil. Remember you will be checking continuity between plug leads 1 and 4 and leads 2 and 3.

7. Coils are secured to the frame with two bolts and are easily removed, if defective, by disconnecting the wires and removing the bolts after the gas tank is taken off.

Low Capacity Excessive Capacity

A defective condenser will cause mounds and matching depressions on the point contact surfaces

IGNITION SYSTEM, 1979–81

The transistorized ignition system encompasses the battery, pulser generator, spark unit, ignition coils, and the spark plugs and caps.

The coils are paired so that cylinders 1–4 and 2–3 fire at the same time. They will probably not fire alone unless there is a high tension leak in the system. Therefore, there will probably be lack of spark at two cylinders at a time.

1. In the event of spark failure, first suspect the spark plugs or caps. Refer to "Ignition System, 1969–1978," Steps 1, 3, and 7.

2. Remove the spark plugs. Connect the caps and lay the plugs on the cylinder head to act as a ground. Remove the generator cover and touch a screwdriver across the rotor and the pulser generator steel core. Repeat several times. There should be a good spark at the plug.

3. Check pulser coil resistance with an ohmmeter after disconnecting the pulsers at the connector beneath the left side cover.

Resistance should be 480–590 ohms at 68°F/20°C. If it is not within this range, replace the pulser coil.

4. To check the spark unit, disconnect the 6-p connector for cylinders 1–4 or the 4-p connector for cylinders 2–3 (top and second from the top respectively) beneath the left side cover.

Attach the positive lead of a DC voltmeter to the blue/with white tube terminal of the 6-p connector or the yellow/with white tube of the 4-p connector. Attach the negative meter lead to ground.

Turn on the ignition switch. Use a jumper wire to ground the blue or yellow terminal intermittently. Voltage should vary from 12 v to 0 v as this is done.

If it does not, replace the spark unit.

STARTING SYSTEM

The starting system consists of the starter motor and clutch, the solenoid, and the handlebar-mounted starter switch. When the button is pressed, the electrical circuit to the solenoid is closed and the solenoid is activated, sending the battery current directly to the starter motor. The starting system is quite reliable and it is unlikely that any major problems will arise.

Testing

The following two paragraphs are applicable to machines with a headlight switch. On models without a switch, a by-pass is incorporated to kill the headlight when the starter is used.

If the starter will not operate, switch on the headlight and observe its intensity. If it is dim when the starter is not being operated, check the battery connections and recharge the battery. If the headlight doesn't light, check the fuse, the battery connections, the ignition switch and its connections, and check the continuity of the wire between the ignition switch and the battery.

If the headlight is bright, press the starter button momentarily and watch the light. If it remains bright, touch a screwdriver blade between the two starter solenoid terminals. If the starter operates, connect a test light between the small yellow/red wire on the solenoid and ground. If the test light comes on as the button is pushed, the solenoid is faulty. If it does not light, look for defective wiring between the starter button and solenoid or between the starter button and ignition switch, or simply a burned out starter button switch. If the starter does not operate and the headlight dims as the main solenoid terminals are bridged, the starter motor is faulty. If the headlight does not dim, look for a bad connection at the starter.

If the starter motor operates freely but will not turn the engine over, the starter clutch is not functioning (a rare occurrence). To remove the starter clutch on the 750, it is necessary only to remove the alternator cover and pull off the rotor to gain access to the clutch.

Starter Motor Service

REMOVAL AND INSTALLATION

1. Disconnect the cable from the positive battery terminal.

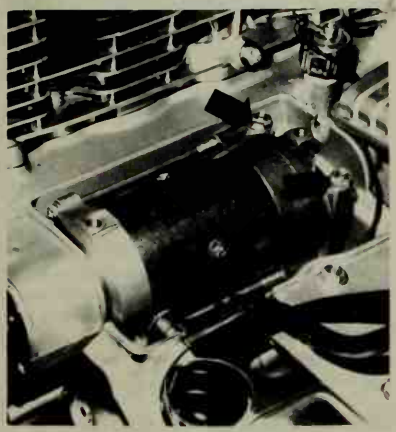
2. Disconnect the starter motor cable from the solenoid.

3. Remove the starter motor cover and the left-side crankcase cover.

4. Unscrew the two starter motor mounting bolts and lift the starter out.

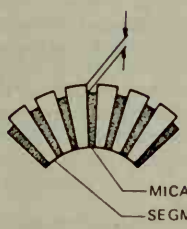
5. Installation is in reverse order of removal.

INSPECTION



1. Take out the two screws and remove the starter side cover.

2. Check electrical continuity between the commutator and armature core using a multitester or test light and battery. If continuity exists, the armature coil is grounded and the complete starter motor unit must be replaced.



3. Check for continuity between all of the

commutator segments. Continuity must exist in each case.

4. Check continuity between the brush that is wired to the stator coil and the starter motor cable. Lack of continuity indicates an open circuit in the stator coil, and the starter motor unit should be replaced.

Starter mounting bolts

Mica undercut

5. Examine the carbon brushes for damage to the contact surfaces and measure their length. Replace the brushes as a set if either one measures less than 5.5 mm (0.22 in.) for 1978 or earlier, or 7.5 mm (0.30 in.) for 1979–1981, or if they are damaged in any way.

6. Brush spring tension should be measured with a small pull-scale. Replace the springs if they have weakened to less than 0.4 kg (0.8 lb) tension for pre-1979 models or 0.6 kg (0.9 lb) on 1979–1981 machines.

7. The mica undercut of the commutator should be maintained at 0.3 mm (0.012 in.). Any carbon deposits should be cleaned out of the commutator grooves, and a piece of hacksaw blade or the like used to increase the undercut depth if necessary. Refer to the illustration.

8. Polish the commutator with fine emery cloth and then clean it thoroughly before installing.

Starter Solenoid

1. If the battery is in reasonably good condition, and nothing at all happens when the starter button is pushed, check the solenoid.

2. Disconnect the starter cable at the starter motor. When the button is pushed, there should be an audible "click" which indicates that the solenoid is opening.

3. If further testing is necessary, remove the solenoid from the machine.

CAUTION: *Be sure to disconnect the cables at the battery before disconnecting the solenoid terminals.*

Connect a fully charged 12-volt battery across the solenoid low-tension leads and check for continuity across the high-tension terminals with an ohmmeter or self-contained test light. If there is no continuity, replace or repair the solenoid.

4. Check for continuity across the low-tension terminals with an ohmmeter or self-powered test light. If there is none, the primary winding of the solenoid is broken, and the unit must be replaced.

5. The primary cause of solenoid malfunction is pitting and/or burning of the contact points inside. It may be possible to restore a solenoid to serviceable condition by taking it apart and dressing the points with a file or emery paper. If this doesn't work, replace it.

6. If starter trouble began just after the starter button housing was disassembled or moved for any reason, check the connections at the switch as they may have come adrift.

ELECTRICAL COMPONENTS

Turn Signal Flasher

If none of the turn signals will flash, chances are that the turn signal flasher has failed. A Signal-Stat 142 flasher is used on the 750 and is located near the battery.

NOTE: *The flasher must be properly grounded to operate.*

Switches

TESTING AND REPLACEMENT PROCEDURES

The operation of any switch can be checked using a multi-tester or test light to determine the electrical continuity of the switch in its different positions. Follow the procedures given below for testing the individual switches. If, during any test, you find that electricity is available at the switch but the switch won't work, make sure that it is not simply a bad ground that is sabotaging it before you buy a replacement. Removal and installation procedures are given after the testing information, as it is not necessary to remove the switches in order to check them.

IGNITION (MAIN) SWITCH

1969–1978

Pull the ignition switch connector apart and check continuity of the switch in its three positions, using the accompanying chart as a guide. If any part of the test shows the switch to be faulty, the switch should be replaced.

The switch can be removed after the retaining nut has been unscrewed.

		BAT	IG	TL 1	TL 2
Wire Color		Red	Black	Brown/ White	Brown
Key position	OFF				
	1	○—○		○—○	
	2	○—○			

1979–1981

After disconnecting the coupler at the switch, check for continuity. The terminals may be identified as follows:

TL2 and TL1 are paired above the other three terminals;

The three terminals are IG, BAT, and P respectively.

In the "P" key position, there should only be continuity between the BAT terminal and P.

In the "ON" position, there should be continuity between BAT and IG and between TL1 and TL2 only.

In the other key positions, there should be no continuity between any of the terminals.

FRONT AND REAR BRAKE LIGHT SWITCHES

The front brake light switch is located between the fork legs just under the headlight. To check its operation, connect the two test leads to the switch terminals, leaving the switch wires connected, and operate the front brake lever. If the tester does not show continuity as the brake is applied (ignition on), check to see if there is electricity at the switch power supply lead (black wire). If there is, replace the brake light switch. If there is not, check the continuity of the black wire between its connections at the brake light switch and ignition switch to determine if there is a loose connector, a short circuit, or a break in the wire.

The front brake light switch can be removed by pulling off the wires and unscrewing it. It may be necessary to bleed the brake after installation.

The rear switch may be tested in the same manner as the front switch. Make sure that it is not simply improperly adjusted and that the spring is strong enough to actuate it. Adjustment can be made by turning the large nut on the switch.

HORN BUTTON AND HORN

If the horn is not working, check to see if it is receiving electricity by connecting the tester between the light green wire at the horn and a good ground (such as the engine crankcase). Turn on the ignition and press the horn button. If the tester responds, the horn is faulty or is not properly grounded. If the tester does not respond, connect the tester lead to the light green wire and press the horn button again (ignition on). If there is still no electricity available, replace the horn button. If there is electricity at the headlight shell but not at the horn, check the green wire for loose connections or a short circuit between the headlight and horn.

NOTE: *Horn loudness can be increased by turning the adjusting screw in (clockwise). The horn button and turn signal switch are in the same switch case, which can be removed after the screws in the bottom half of the case are taken out.*

TURN SIGNAL SWITCH

1969–1978

To check operation of the turn signal switch, pull apart the connectors for the orange, gray, and blue wires. Check continuity of the switch in its three positions with a multitester or test light and battery, using the ac-

companying chart as a guide. (Be sure to connect the tester to the three wire ends leading to the switch, not the turn signal bulbs.) If any part of the test shows the switch to be faulty, it should be replaced.

Knob	Blue Lead	Gray Lead	Orange Lead
R	○	———	○
OFF (center)			
L		○	——— ○

To remove the switch, take out the screws at the bottom of the switch case and separate the upper and lower halves of the switch.

1979–1981

Test procedures are similar to those described for earlier models, above. "R" should give continuity between blue and gray; "L" should give it between gray and orange, as above. In addition, "R" should give continuity between brown/white and orange/white; "L" should give continuity between brown/white and blue/white; "OFF" should give continuity between brown/white, orange/white, and blue/white.

LIGHTING SWITCH

1969–1978

To check operation of the lighting switch pull apart the connectors for the black, blue brown/white, and white leads. Check continuity of the switch in its different positions using the accompanying chart as a guide. (Be sure to connect the tester to the three wire ends leading to the switch, not the lights. The brown/white wire is for the highbeam in

Wire Color		IG Black	HB Blue	TL Brown/White	LB Whi
	H	○	——— ○	——— ○	
ON	P	○		——— ○	
	L	○		——— ○	——— ○
OFF					

dicator light.) If any part of the test shows the switch to be faulty, it should be replaced. The switch can be removed after the screws in the bottom half of the case have been taken out.

1979–1981

"HI" should give continuity between blue/white and blue;
"N" between blue/white, blue, and white;
"LO" between blue/white and white

IGNITION KILL SWITCH

Check operation of the kill switch by pulling apart the connectors for the black and black/white wires in the headlight shell, and testing for continuity of the switch in both the on and off positions. Electrical continuity in either of the off positions, or *lack* of continuity in the on position, indicates a bad switch. (Be sure to connect the tester to the wire ends leading to the switch, and not to the ignition coil and ground.)

Ignition Kill Switch

Wire Color	Black	Black/White
ON	○	——— ○
OFF		

The switch can be removed after the screws in the bottom half of the case have been taken out.

STARTER BUTTON

Check operation of the starter button by connecting the tester between the yellow/red wire and ground. Lack of continuity with the button depressed indicates a bad switch.

Starter Switch

Wire Color	Ground	Yellow/Red
ON	○	——— ○
OFF		

The switch can be removed after the screws in the bottom half of the case have been taken out.

OIL PRESSURE SWITCH

When oil pressure drops below approximately 7 psi, the oil pressure switch closes, completing the ground circuit of the oil pressure warning light which will then light up. There is no power supplied to the oil pressure switch, so it must be tested using equipment with its own power source such as a multimeter or test light and battery. Connect the meter leads to the oil pressure switch lead and to ground. If the tester does not respond, the switch has not closed and is defective. (The engine must not be running or else oil pressure will be too high to allow the switch to close.)

The oil pressure switch is located on top of the crankcase (just behind the cylinders). To remove, simply unscrew the switch unit after the lead has been disconnected.

NEUTRAL INDICATOR SWITCH

In the same manner as the oil pressure switch, the neutral indicator switch closes and completes the ground circuit to the neutral indicator light when the transmission is placed in neutral, at which time the light should go on. If the light does not go on, connect a tester with its own power supply to the switch lead and to ground. Lack of continuity

Electrical Specifications

Model	CB750 (5-speed) 1969–1978	CB750A	CB750, CB900 1979–1981
ALTERNATOR			
Type		3-phase excited field

①K3 and later

(with the transmission in neutral) means that the switch should be replaced.

The switch is located at the underside of the engine on 1969–1978 models, and near the engine sprocket on more recent machines.

CLUTCH SWITCH

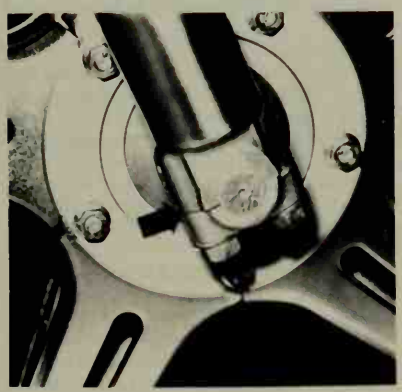
On late models which incorporate a clutch safety switch, disconnect the leads at the clutch.

There should be continuity when the clutch is pulled in.

To remove the switch, disconnect the wiring, remove the clutch lever, and remove the switch.

The switch has a small protrusion which must point towards the handlebar when it is installed.

CHASSIS



WHEELS

Front Wheel Assembly

REMOVAL AND INSTALLATION

Single Disc

1. Raise the front wheel off the ground by placing a support under the engine.
2. Disconnect the speedometer cable from the front hub.

Be sure that the axle cap is installed so that the gap (arrow) is at the rear

3. Remove the four axle clamp nuts (two on each side) and withdraw the front wheel assembly from the forks.

CAUTION: *Do not operate the front brake while the wheel is removed or the caliper piston will be forced out of the cylinder.*

Installation is in reverse order of removal.

Note that the front axle holder clamps are machined so that the forward mating surface is slightly higher than the rear mating surface. They must be installed correctly. Place a straightedge on the mating surfaces to determine which end is higher, and *install the high mating surface forward.* On late models, install the clamps so that the "F" mark is at the front. Tighten the forward retaining nut first, drawing the forward mating surface of the holder clamp flush against the fork leg mating surface and then tighten the rear nut. Proper torque is 13–18 ft. lbs. for both nuts.

Twin Disc

1. Support the front wheel off the ground by placing a support beneath the engine.
2. Disconnect the speedometer cable.
3. Unbolt and remove one of the brake calipers from the fork sliders. It is not necessary to disconnect the brake lines, but a piece of cardboard or the like can be inserted between the brake pads to prevent their closing together.

CAUTION: *Do not operate the brake lever while the calipers are removed.*

4. Remove the four axle clamp nuts (two on each side), take off the clamps, and take out the wheel.

Installation is the reverse of removal. Be sure that the axle clamps are installed correctly: they are machined unevenly, and the higher side must be installed towards the front of the motorcycle. Tighten the nut for the high side first.

On late models, "F" is marked on the axle clamps and this must be installed towards the front of the fork. Proper torque is 13–18 ft. lbs.

Wheel Bearings

REMOVAL

1. After removing the front wheel, unscrew the axle nut and withdraw the axle and axle collar.
2. Remove the screw and remove the speedometer gearbox from the hub.
3. Bend back the locktabs and unbolt and remove the brake disc.
4. Remove the speedometer gearbox drive flange retainer. Remove the drive flange.
5. Unscrew the wheel bearing retainer from the other side of the hub. Withdraw the bearings and spacer.

Bearings are usually driven out with a hammer and drift. Once removed, however, bearings should be replaced with new ones. Check bearing condition in place if possible.

INSTALLATION

Assembly is the reverse of the above.

Note the following points:

a. Pack the bearings with a good grade of wheel bearing grease. Put a small handful of the grease in the hub as well.

Removing a wheel bearing

b. Do not forget to install the spacer in the hub before installing the bearing.

c. Bearings may be driven into place using Honda service tool No. 07048-30001 or a suitable substitute.

d. Use a new oil seal and lubricate it with oil to make installation into the bearing retainer easier.

e. Stake the bearing retainer in two places after it is installed.

NOTE: *The front hub on the CB 750 (1970 and later) is narrower than on the CB 750 (1969). In addition, the speedometer drive flange and flange retainer and the brake disc mounting bolts are changed to fit the narrower hub. It is important that the correct disc mounting bolts are used (if removed) or the disc will not be securely mounted.*

Rear Wheel Assembly

REMOVAL AND INSTALLATION

Rear Drum Brake

1. Place the bike on the center stand.
2. Remove the rear brake adjusting nut and separate the brake rod from the lever.
3. Disconnect the brake anchor from the hub by removing the lockpin and unscrewing the nut and bolt.
4. Loosen the chain adjuster locknuts and back the bolts out.
5. Remove the cotter pin and loosen the axle nut. Turn the adjusters downwwrd.
6. Remove the lockbolts and chain adjuster stop plates. Push the wheel forward and lift the chain off the rear sprocket. Withdraw the wheel rearward from the swing arm.

Installation is in reverse order of removal. Tighten the axle nut to 58–72 ft. lbs.

Rear Disc Brake (Chain Drive)

1. Loosen the locknut on the chain adjusters and back the adjusters out. Remove the cotter pin from the rear axle, and remove the axle nut.
2. Slide the wheel forward in the swing arm and lift the chain off the sprocket. The wheel can now be removed.

NOTE: *Do not apply the rear brake with the wheel removed, as the piston may be forced out of the caliper.*

3. When installing, tighten the rear axle nut to 58–72 ft. lbs.

Rear Disc Brake (Shaft Drive)

1. Park the machine on the center stand.
2. Remove the axle nut cotter pin and remove the axle nut.
3. Loosen the axle pinch bolt and pull out the axle. Note washer location.
4. Raise the brake caliper. Pull the wheel to the left to disengage the drive flange and remove it from the machine.

NOTE: *Do not apply the rear brake with the rear wheel removed, as the caliper piston may pop out.*

5. When installing, grease the drive flange. Tighten the axle nut to 58–72 ft. lbs., and the axle pinch bolt to 17–21 ft. lbs.

Wheel Bearings

REMOVAL

1. After removing the rear wheel, remove the axle and brake plate from drum brake models.

2. Tap the sprocket and sprocket plate out of the hub with a soft drift or block of wood.
3. Unscrew the bearing retainer(s) and drive the bearings out of the hub.
4. The bearing in the sprocket hub can be removed in the same manner.

INSTALLATION

Reverse the removal procedure. Note the following points:

a. Pack the bearings with wheel bearing grease. Place a small handful in the hub as well.

b. Do not forget the bearing spacer.

c. The bearings may be driven into place with Honda tool No. 07048-30001 or a suitable substitute.

d. Use a thread-locking compound on the bearing retainer(s).

e. Apply a small quantity of grease to the friction surfaces of the flange and wheel hub.

FRONT BRAKE SERVICE

Single Disc, 1969–1978

Before attempting work on the hydraulic disc brake system, note the following points:

a. Never use brake fluid from an old or an unsealed container. Brake fluid is hydroscopic—it absorbs moisture—and therefore quickly becomes useless unless kept in a sealed environment.

b. Never reuse brake fluid which has been flushed from the system.

c. The system uses DOT 3 brake fluid. This standard is marked on the can. Do not use any other type. Do not mix types or brands of brake fluid, as they may not be compatible.

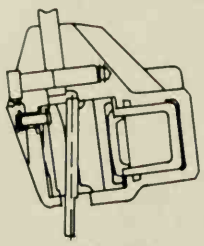
d. When handling brake fluid, cover all painted parts (such as the gas tank) which may be accidentally damaged by spillage. Brake fluid will remove paint in short order.

e. Keep brake fluid away from the pads and disc surfaces. If there is contact, clean them off immediately with a non-oily solvent. If pads cannot be cleaned, replace them.

f. With the exception of the pads and disc, all internal caliper and master cylinder parts should be cleaned in new brake fluid *only*. Do not attempt to clean these parts in solvents of any type.

g. Any time any of the brake line connections have been loosened or disconnected, the system must be bled to remove air. Refer to the section below.

PAD REPLACEMENT



1. To determine pad wear on the CB 750 (1969) and 750K1, measure the clearance between the caliper and the disc with a feeler gauge as shown. When the clearance is less than 2.0 mm (0.08 in.), the pads should be replaced.

2. On other models, check the pads for wear by noting the red wear indicator line. Replace the pads when they are worn close to this red line.

3. Remove the front wheel. Remove the two bolts from the side of the caliper and remove the right-side caliper half.

4. Remove the pad from the piston side of the caliper. Withdraw the cotter pin and remove the pad from the other caliper half.

5. Before installing the new pads, apply a small amount of silicone grease to the pad sliding surfaces on the caliper as shown. The grease serves to keep pad operation smooth by repelling dust and water as well as providing lubrication. Use grease sparingly and do not allow it to contact the pad friction material.

Checking pad wear on early (1969–1970) models

6. Install the new pads in the caliper halves and bolt the caliper together.

7. Install the front wheel and adjust the brake as explained in the following section. Avoid heavy braking until at least 50 miles have been covered.

ADJUSTMENT

1. Loosen the caliper adjuster bolt locknut and turn the bolt until the inside pad (closest to the wheel) lightly contacts the disc.

2. Turn the adjuster bolt in the opposite direction about ¼–½ turn and tighten the locknut.

3. On the very early models, provision is made for adjustment of brake lever free-play at the lever. Loosen the locknut and turn the adjuster screw until ¼–½ in. free-play is obtained at the end of the lever. Retighten the locknut to 13–17 ft. lbs. The lever is not adjustable on the other models.

CALIPER

Leakage of brake fluid from around the caliper piston indicates that the caliper assembly is worn or damaged, and the cause should be investigated immediately. To remove, inspect, and rebuild the caliper assembly:

1. Remove the front wheel.

2. Unscrew the hydraulic line connection at the caliper and catch the fluid that drains from the line in a suitable container and dispose of it. (Do not reuse old brake fluid.)

3. Unscrew the three caliper mounting bolts at the left fork leg and remove the caliper.

4. Remove the two bolts and separate the caliper halves.

5. Remove the pad seat from the caliper piston and withdraw the piston.

6. Remove the seal from the cylinder and replace if damaged. Cylinder bore diameter should not exceed 38.22 mm (1.504 in.) and piston diameter should not be less than 38.11 mm (1.500 in.). Maximum calculated clearance between the piston and cylinder is 0.115 mm (0.0045 in.). Replace parts as necessary. Clean all components and dry with compressed air.

7. Use a new seal in the cylinder bore and lubricate in throughly with fresh brake fluid before installing. Make sure that it is seated properly in its groove.

8. Lubricate the piston with brake fluid and install it in the cylinder. Be careful not to twist the seal or force it out of the groove. Install the pad seat on the piston.

9. Reinstall the brake pads in the caliper halves. Use new pads if the old ones have been in contact with brake fluid.

10. Bolt the caliper halves together and remount the caliper assembly on the fork leg.

11. Connect the hydraulic line and replace the front wheel.

12. Bleed and adjust the brake (refer to the appropriate headings in this section).

MASTER CYLINDER

Brake fluid leakage around the brake lever and excessive lever travel (after bleeding the brake to make sure that there is no air trapped in the hydraulic system) are indications of master cylinder malfunction. The rebuilding procedure is as follows.

CAUTION: *Be very careful, when removing and replacing the master cylinder, in filling the reservoir. Brake fluid can damage paint and plastic, and extreme care should be exercised in its handling. Wipe up any spills immediately.*

1. Place a cloth underneath the connection to absorb any spilled fluid and disconnect the brake hose from the master cylinder.

2. Unscrew the clamp bolts and remove the master cylinder from the handlebar. Unscrew the reservoir cap and discard the brake fluid.

3. Remove the rubber boot. Remove the snap-ring and withdraw the washer, piston, secondary cup, primary cup, spring, and check valve.

4. Check the cylinder bore for scoring and pitting, and measure the wear using a dial indicator. Bore diameter should not exceed 14.06 mm (0.553 in.). Replace the master cylinder assembly if damaged or worn.

5. Check the piston diameter. Minimum allowable diameter is 13.94 mm (0.549 in.).

6. Clean all components in solvent and dry with compressed air.

7. Use a new seal and lubricate it with fresh brake fluid. Install the components in the bore as removed.

8. Mount the master cylinder on the handlebar and connect the brake hose. Do not forget to install the two washers at the connection.

9. Fill the reservoir to the level mark with brake fluid and bleed the brake. (Use DOT 3 brake fluid.)

BLEEDING

1. Top up the reservoir with brake fluid and replace the cap to keep dirt and moisture out and the fluid in. Cover the gas tank with a thick cloth to avoid damage due to spilled brake fluid.

2. Attach one end of a small diameter rubber hose to the bleed valve on the caliper, and place the other end in a jar which contains several inches of clean, new brake fluid. Be sure that the end of the hose is submerged in this fluid. Arrange the hose so that it loops upward after leaving the bleed valve, and see that it has no kinks or sharp bends.

3. Pump the brake lever rapidly several times until some resistance is felt and, holding the lever against the resistance, open the bleed valve about one-half turn. When the

Bleeding the brake system

lever bottoms, close the valve (do not overtighten) and then release the lever.

4. Repeat this operation until no more air is released out of the hose and the brake lever is firm in operation. Check the fluid level in the reservoir often to make sure that it doesn't go dry and draw more air into the system. Do not reuse fluid that has been pumped out of the system. Do not use fluid that has been stored for more than a few weeks after the seal on its container has been opened, as brake fluid will absorb moisture from the air and may corrode the master cylinder and caliper.

5. Refill the reservoir to the level mark when through (but do not overfill). Avoid overtightening the cap or fluid will weep around the cap edge.

DISC SERVICE

The brake disc normally requires no service of any kind. However, if the disc becomes scored for any reason, it should be replaced and a new set of pads should be installed. A badly scored disc will reduce the effectiveness of the brake and shorten pad life considerably. If the front brake lever oscillates or fluctuates when the brake is applied at speed, the indication is that the brake disc is warped or bent. Check the run-out of the disc with a dial indicator and replace it if run-out exceeds 0.3 mm (0.012 in.). To replace the disc:

1. Remove the wheel.
2. Bend back the locktabs (if fitted), unscrew the nuts, and remove the disc from the hub.
3. Mount the new disc on the hub and tighten the nuts evenly, using new locktabs (if fitted) or thread-locking compound to secure the nuts.
4. Examine the brake pads and replace them if they are close to the limit of wear or have worn in an unusual pattern.

Twin Disc, 1977–1978

The CB750F (77–78) is equipped with two brake calipers. The calipers are the same as these found on the rear of 1977–1978 models equipped with a rear disc brake. Refer to "Rear Brake Service, Disc Brake Models," below.

When bleeding the system, bleed the caliper furthest from the master cylinder (left side) first.

Single Disc, 1979–1980

PAD REPLACEMENT

1. Remove the caliper cover. Take out the clip.
2. Push the caliper as far as possible towards the wheel and push the piston all the way in.
3. Remove the pins, brake pads, and shim.
4. When fitting the new pads, apply a coat of silicon grease to both sides of the shim.
5. Install the new pads with the shim on the piston side of the pad. Fit the pins, clip, and cover.

CALIPER

1. Taking care to avoid damage to painted surfaces, place a container beneath the caliper brake line banjo, and remove the banjo bolt.
2. Loosen the two caliper shaft bolts gradually and evenly while pressing them in.
3. Remove the caliper from the fork slider.
4. Remove the piston boot.
5. Place a rag over the piston and hold the caliper with the piston facing down. Apply low-pressure compressed air to the banjo bolt fitting to push out the piston.
6. Pry out the fluid seal with a small screwdriver or the like, taking extreme care not to scratch the caliper bore.
7. Clean all metal parts in clean brake fluid. All rubber parts should be replaced as a matter of course.
8. Check the piston outside surface for scratches or signs of wear, and replace it if the surface is not perfect. Measure the OD of the piston. If it is under 42.765 mm (1.6837 in.), replace it.
9. Check the caliper bore for like damage. Make sure that the fluid seal groove is perfectly clear of foreign matter. Measure the ID of the caliper bore. If it is more than 42.915 mm (1.6896 in.), replace it.
10. Assembly is the reverse of disassembly. Use all new rubber parts. Be sure to lubricate the piston and seal with medium grade hi-temperature silicon grease or some new brake fluid before assembly.

Be sure that the fluid seal is firmly seated in its groove.

Be sure to install the piston with the boot lip facing out.

Tighten the caliper shaft bolts to 22–29 ft. lbs.

Caliper mounting bolts

Measuring piston diameter

CALIPER CARRIER

The caliper carrier will remain on the fork slider when the caliper halves are removed. When rebuilding the system, remove the two carrier bolts and separate the components. Clean all metal parts in clean brake fluid. Replace the caliper shaft o-rings and boots. Lubricate the o-rings with silicon grease or new brake fluid before assembly. When assembling, be sure that the boots are seated in the caliper shaft grooves. Tighten the carrier bolts to 22–29 ft. lbs.

MASTER CYLINDER

The master cylinder components are the same as described for the "Single Disc, 1969–1978." Refer to that section, above.

DISC

Replace the disc if measured thickness is less than 6.0 mm (0.24 in.) at any point, or if the disc surface is warped, scored, or otherwise damaged.

BLEEDING

Bleeding procedures are carried out in the same manner as outlined for the "Single Disc, 1969–1978," above. Refer to that section.

Twin Disc, 1979–81

PAD REPLACEMENT

1. Remove the two caliper allen head bolts. Remove the caliper from the carrier.
2. Remove both brake pads and the shim.
3. Install the new brake pads and the shim. Install the shim with the arrow facing upwards.
4. When fitting the caliper, tighten the two allen bolts gradually and evenly to 11–14 ft. lbs.

CALIPER

Working procedures are the same as for "Single Disc, 1979–80," above. Specifications differ.

Caliper piston replacement limit is less than 38.09 mm (1.500 in.).

Caliper bore replacement limit is 38.24 mm (1.506 in.).

MASTER CYLINDER

Procedures are the same as for the master cylinder under "Single Disc, 1969–1978," above. Specifications differ.

Master cylinder bore diameter should be no more than 15.925 mm (0.6270 in.).

Master cylinder piston diameter should be no less than 15.815 mm (0.6226 in.).

DISC

Replace the disc if the thickness at any point is under 4.0 mm (0.16 in.), or if the disc is scored or warped.

BLEEDING

Refer to the "Single Disc, 1969–78," section for bleeding procedures.

REAR BRAKE SERVICE

Disc Brake, 1977–78

PAD REPLACEMENT

1. Remove the 5-mm bolt from the top of the caliper and lift up the pad cover.
2. Push down on the pad set spring and withdraw the two pad pins from the right caliper half.
3. Remove the two brake pads from the top of the caliper. If the same brake pads are to be reused, mark the pads so that they can be installed in the caliper half from which they were removed so that the direction of rotation will not be reversed.
4. To install new pads, drop them in place. Press the set spring down and insert the two pad pins in place through the pads. Be sure that the set spring is hooked on the narrow section of the pins.
5. Replace the pad cover and secure with the 5-mm bolt.

CALIPER

Removal

1. Remove the banjo bolt from the caliper and disconnect the brake line. Allow the fluid to drain from the line into a suitable container. Wipe up any spilled fluid immediately. Place a plastic bag around the end of the line and banjo bolt to prevent dirt from entering the system.
2. If the caliper is to be disassembled, loosen the two caliper set bolts at this time as they may be difficult to loosen once the caliper is removed.
3. Disconnect the brake anchor from the front of the caliper.
4. Remove the axle and lift off the caliper as an assembly.

Disassembly

1. Remove the 5-mm bolt from the top of the caliper. Remove the wear indicator cover and the pad cover.
2. With an 8-mm allen wrench remove the caliper set bolts and separate the two caliper halves.
3. Remove the o-ring from between the caliper halves.
4. Lift out the set spring, pads, and pad pins.
5. Remove the securing clip from the dust seal and remove the dust seal.
6. To remove the piston, apply compressed air to the inlet hole. Be careful to catch the piston as it is forced out.
7. Remove the piston seal, being careful not to scratch the cylinder bore. This seal should be replaced with a new one once removed.

Inspection

1. The bore of the caliper should be between 38.18–38.20 mm (1.5031–1.5039 in.). If the bore exceeds 38.215 mm (1.5045 in.) for either cylinder, both caliper halves should be replaced.
2. The piston outside diameter should be between 38.115–38.480 mm (1.5006–1.5150 in.). If either piston is smaller than 38.105 mm (1.5002 in.) the piston should be replaced.

Assembly

1. Install the piston seal into the groove in the caliper half.
2. Place a thin coat of silicon grease on the bore of the caliper and the piston seal.
3. Install the pistons and dust seals.
4. Install the pads, pad pins, and set spring. Install a new o-ring in the fluid passage between the two caliper halves, and bolt the caliper halves together. Tighten the bolts to 18–21 ft. lbs.
5. Install the pad cover and the wear indicator cover and secure with a 5-mm bolt.

Installation

1. Hold the caliper in place and install the axle.
2. Connect the brake anchor and brake line. Be sure that there is a washer on either side of the banjo fitting.
3. Bleed the system.

MASTER CYLINDER

Removal

1. Disconnect the rear brake line from the caliper by removing the banjo bolt. Take care not to lose the washers fitted to either side of the brake line fitting. Drain the master cylinder into a suitable container by pumping the brake pedal.
2. Remove the cotter pin from the brake rod pin, then remove the brake rod pin.
3. Remove the two mounting bolts and lift off the master cylinder.

Disassembly

1. Loosen the 8-mm not on the push rod and remove the brake rod joint from the end of the rod. Remove the 8-mm bolt and pull off the rubber boot.
2. Remove the snap-ring from the bottom of the master cylinder and pull out the brake rod.
3. Remove the piston and secondary cup assembly from the bottom of the cylinder.
4. Remove the primary cup, spring, and check valve.
5. Remove the master cylinder cap and diaphragm.

On early CB750F models up to frame No. CB750F-1010687, the master cylinder had a separate oil reservoir. On later models the reservoir is integrated with the master cylinder body. To remove the reservoir from the early models:

6. Remove the two screws located in the bottom of the reservoir and lift out the bottom plate.
7. Lift off the reservoir and o-ring.

Inspection

1. The bore of the master cylinder should be between 14.000–14.043 mm (0.5512–0.5529 in.). If the bore exceeds 14.055 mm (0.5533 in.), the master cylinder should be replaced.
2. The outside diameter of the piston should be between 13.957–13.980 mm (0.549–0.550 in.). If the piston is smaller than 13.940 mm (0.548 in.), the piston should be replaced.
3. Inspect the seals. If any are hard or scored, they should be replaced.

Assembly

1. Coat all parts of the master cylinder, including the bore, in clean brake fluid before installing them.
2. Install the check valve on the end of the spring, and be sure that it is facing the proper direction. Install the spring and check valve into the cylinder.
3. Install the primary cup so that the cupped side is facing the spring.
4. Install the piston and secondary cup. Install the piston so that the secondary cup is towards the bottom of the master cylinder. The lips of the secondary should face the top of the cylinder.
5. Install the 18-mm snap-ring, push rod, rubber boot, 8-mm nut, and brake rod joint.

Installation

1. Hold the master cylinder in place and install the two mounting bolts.
2. Connect the brake rod joint to the brake shaft with the brake rod pin and secure with a new cotter pin.
3. Connect the brake line to the rear caliper. Be sure to install a washer on both sides of the fitting.
4. Fill the master cylinder with new DOT 3 brake fluid and bleed the system.

BRAKE PEDAL HEIGHT

The height of the brake pedal can be adjusted by screwing the brake rod joint up or down on the master cylinder push rod.

1. Loosen the brake rod joint locknut.
2. Separate the brake rod joint from the pedal shaft by removing the brake rod pin.
3. Turn the brake rod joint either up or down to effect adjustment.
4. The clearance between the brake pedal and the footrest should be at least 5 mm (0.19 in.).
5. When adjustment is correct, connect the brake rod joint to the brake shaft with the brake rod pin, and secure in place with a new cotter pin.

BLEEDING

Refer to the section on bleeding the front brake, above.

DISC SERVICE

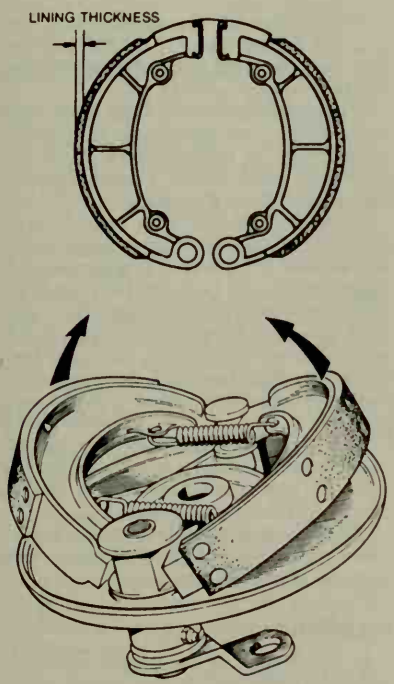
Service to the front and rear disc are the same. Refer to the "Disc Service" section for front wheel, above.

Disc Brake, 1979–1981

This rear disc brake is the same as the front twin disc system described above. Refer to those sections.

Rear disc thickness should be no less than 6.0 mm (0.24 in.).

Drum Brake Models



BRAKE SHOE REPLACEMENT

Rear brake lining wear on newer models can be determined by means of the wear indica-

tor pointer fitted to the brake lever on the hub. If the pointer lines up with the red slash mark when the brake pedal is fully depressed, the linings are worn beyond use and should be replaced.

On older models, observe the angle formed by the brake lever on the hub and the brake rod when the brake is fully applied. When the lever and rod form an angle greater than 90°, the shoes should be replaced. The replacement procedure is as follows:

1. Remove the rear wheel.
2. Unscrew the axle nut and withdraw the axle. Separate the backing plate from the brake drum.
3. Remove the cotter pin and washer from each brake shoe pivot and lift the shoe away from the backing plate. Minimum acceptable lining thickness at any point is 2.0 mm (0.08 in.) for all models.
4. Check the linings for scoring or embedded foreign matter, and replace them if necessary. Oil or grease-impregnated linings should also be replaced.

Removing the brake shoes

5. Break the glaze on the linings with some medium sandpaper, but be sure to clean them thoroughly before installation.
6. Check the condition of the brake springs, and replace them if badly rusted or if the ends are deformed.
7. Apply a *light* coat of grease to the brake shoe pivots and the actuating cam. Install the springs and shoes as on removal, using new cotter pins.
8. Inspect the condition of the brake drum surfaces. There should be no scoring. If scored, the drum can sometimes be salvaged by having it turned down on a lathe. Refer work of this nature to a qualified machinist.
9. Measure the inside diameter of the drum in two directions, perpendicular to each other. Maximum allowable diameter is stamped on the drum. A difference in the two readings indicates that the drum is warped. This condition is sometimes felt in an "off-on-off" feeling when applying the rear brake, and it, too, may be remedied by turning down the drum.
10. Clean the drum thoroughly, removing all dirt and dust.
11. Assemble the drum and hub and the axle and install the wheel. Adjust the brake so that there is about 25.0 mm (1.0 in.) of freeplay at the pedal before the shoes contact the drum. Avoid heavy braking for a few miles if new shoes have been fitted.

Parking Brake (750A)

DISASSEMBLY

1. Remove the rear brake lever by removing the pinch bolt and carefully pulling the lever from its splined shaft.
2. Slide the ratchet mechanism dust cover up along the cables and out of the way.
3. Unscrew the parking brake switch. Disconnect the parking brake cable from the ratchet lever and unscrew the adjuster from the ratchet base.
4. Remove the rear brake joint, the circlip and washer, ratchet case lever and pawls, and the return spring.

INSPECTION

1. Clean all parts in solvent to remove old grease.
2. Check the spring for tension. Make sure the spring ends are in good condition.
3. Check the ratchet case for wear of the teeth and inspect the pawls for wear as well. Replace the assembly if the teeth or pawls are chipped or worn.

ASSEMBLY

1. Grease the ratchet assembly shaft and the inside of the ratchet case with a good grade of chassis grease.
2. Assembly is the reverse of disassembly. Be sure that the return spring is properly anchored. Screw the switch in all the way. Adjust the cable to 2 mm (0.08 in.) of freeplay as outlined in chapter 2, "Maintenance."

FRONT FORKS (STANDARD)

Removal

1. Support the front wheel off the ground. Remove the front wheel and fender.
2. Remove the caliper(s) from the fork slider.

CAUTION: *Do not allow the caliper(s) to hang by the brake hose. Tie them out of the way with string or wire.*

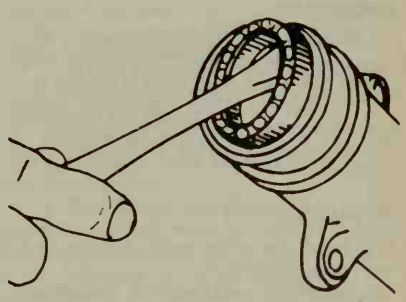
3. Remove the fork filler cap at the top of each fork leg.

NOTE: *It may be necessary to remove the handlebars to do so, but the controls may be left connected, and the bars gently laid to one side when the mounting bolts are removed.*

4. Loosen the upper and lower triple clamp pinch bolts.
5. Grasp each fork leg, in turn, and remove it from the triple clamps by pulling downward. If this is difficult, install the filler cap(s), threading them in several turns, then strike them sharply with a plastic mallet or the like to drive the fork leg down and out of the triple clamps.

Disassembly

1. Remove the fork spring and gaitor (if fitted). Drain the fork oil.
2. Remove the fork slider dust seal, if fitted. Remove the slider oil seal circlip. On K2 and earlier models the slider can be removed at this point.
3. Remove the allen bolt at the bottom of the slider (K3 and later) and separate the fork components.
4. On 1973 and later models, the slider oil seal will remain in the slider. Oil seals must always be replaced with the forks are disassembled. Pry out the old seal with a screwdriver or a hooked tool, protecting the lip of the slider with a piece of wood or soft metal pad beneath your lever. Drive new seals straight in until seated. An old seal can be used to drive in the new seals. Be sure the seals are driven straight in and not cocked or tilted. Seals should be driven in just far enough to allow fitting the circlip.
5. On 1972 and earlier models, the seal will remain on the fork leg with the other fork components once the slider is removed. Take off the components after removing the snapring at the bottom of the fork leg, and then those above the damper piston.



Oil the lips of seals before assembly.

Inspection

1. Inspect the fork tubes for bends such as might have been incurred in an accident. Replacement is recommended rather than attempting to straighten bent fork tubes.
2. Check that the surface of the tube on which the slider components move is smooth and free of rust or scoring. Minor rusting should be removed with fine emery cloth.

On K3 and later fork tubes, the chrome plating must be in perfect condition. If it is peeled or damaged, the fork tube must be replaced if oil leaks occur.

3. Check the spring condition. Make sure the spring heights are equal and that they are within the lengths specified in the "Chassis Specifications" chart.
4. Check that the damper rod (where fitted) is straight, and that all damper components are clean.
5. Check the slider bushing and the damper piston for scoring or wear, and replace them if damaged (K2 and earlier models).
6. Replace the fork filler cap o-rings if they are not in good condition.
7. Clean all metal parts thoroughly in a solvent and lubricate them lightly with fork oil before assembly.

Prying out a front fork oil seal

Assembly

Assembly is the reverse of disassembly. Note the following points:

a. On K2 and earlier forks, lubricate the components thoroughly and assemble them on the fork tube. Slip on the fork slider and use a seal driver or a suitable substitute to seat the seal. Fit the circlip.

b. On K3 and later forks, be sure the rebound spring is in place.

Installation

1. Install each fork leg into the triple clamp and align the top of each fork tube with the surface of the upper triple clamp.

2. Tighten the upper triple clamp pinch bolts, the lower triple clamp bolts, and fill the forks with the recommended grade and quantity of oil (see chapter 2, "Maintequantity of oil.

3. The remainder of the procedure is the reverse of removal.

FRONT FORKS (AIR TYPE)

Removal

1. Remove the handlebars.
2. Disconnect the air hose and remove the connector from the right fork tube.
3. Disconnect the air hose from the left fork.
4. Remove the upper triple clamp.
5. Remove the headlight.
6. Remove the front wheel.
7. Loosen the lower triple clamp pinch bolts and pull the fork legs out of the triple clamp.

Disassembly

CAUTION: *Depressurize the fork tubes before attempting disassembly. The fork caps are under both air and spring pressure. Use caution when removing them.*

1. Fork seal replacement does not require separating tube and slider.
2. Depressurize the fork leg and remove the valve stem and hose connector. Install the special plugs into the cap.
3. Remove the caps.
4. Remove the oil seal dust cover and snap-ring. Use a magnet to take out the back-up plate.
5. Extend the fork leg. Fill the leg with ATF and fit the cap.
6. Compress the fork leg until the seal is forced out.
7. Remove the fork slider bolt and pull the slider and fork leg apart until they separate.

Inspection

1. Replace the long fork spring if it measures less than 429 mm (16.9 in.), and the shorter if it is less than 165.5 mm (6.52 in.).
2. Replace the slider bushings if copper appears on more than ¾ of the surface.
3. Minimum fork tube OD is 36.90 mm (1.453 in.).

Assembly

1. Install the slider seals with the markings facing upwards.
2. Install the snap-ring with the radiused side facing down.
3. Fill each fork leg with 280 cc (9.5 oz) of ATF.
4. Tighten the cap bolts to 11–22 ft. lbs.
5. Standard air pressure is 11–16 psi.

CAUTION: *Use a hand-operated air pump only to fill fork tubes.*

Installation

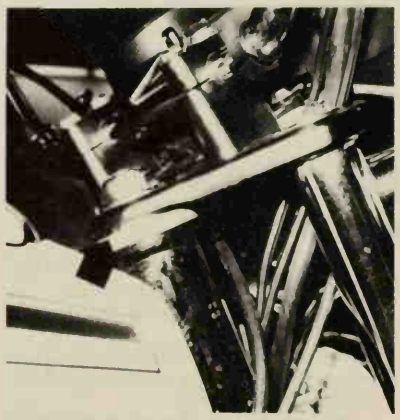
Reverse the removal procedures.

Torques:

Steering stem nut: 58–87 ft. lbs.
Upper triple clamp pinch bolts: 7–9 ft. lbs.
Lower triple clamp pinch bolts: 33–40 ft. lbs.

STEERING STEM ASSEMBLY

Bearing Adjustment



1. On 1969–1978 models, the steering stem bearings are uncaged #8 or ¼ in. balls. They are adjusted by means of a ring nut beneath the upper triple clamp.

On 1979–1981 models, a set of tapered roller bearings is used.

2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender and place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn. An alternate method is to grasp the fork sliders and attempt to move them back and forth in line with the motorcycle. No play should be noted.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.

The bearings are adjusted by means of the adjuster nut

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The fork should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

6. To adjust the bearings, remove the upper triple clamp. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above.

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Disassembly

1. Remove the front wheel, front forks, and handlebars.
2. Loosen the rear pinch-bolt on the triple clamp. Unscrew the steering stem nut and disconnect the speedometer and tachometer cables from their instruments. Remove the upper triple clamp.
3. Disconnect the wiring inside the headlight shell and remove the headlight shell and the fork ears.
4. Loosen the steering stem adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race and the ball bearings from the top race.
5. Carefully pull the steering stem out from the bottom. Some of the ball bearings from the lower race will probably fall out at this time so be prepared for this.
6. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. These will have to be pried off with a chisel, therefore only remove them if necessary.
7. The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

New races are installed with a suitably sized bearing driver, i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

These races can also be installed using a block of hard wood of sufficient size to cover the race in place of a bearing driver.

Installation

1. Install the dust seal washer, dust seal, and lower cone race on the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the upper race in the frame lug.
2. Embed 18 balls into the grease of the top frame lug and 19 balls into the grease of the lower cone race.
3. When the balls are in place, slip the steering stem through the frame lug and hold it in place while refitting the top cone race and threading on the adjuster nut.
4. Tighten the adjuster nut all the way by hand, rotating the steering stem to work the grease into the balls.
5. Tighten the adjuster nut until the steering stem turns freely, but has no play.
6. Install the fork tubes, headlight assembly, and upper triple clamp, flat washer, and steering stem nut. Check that the stem moves freely to the steering lock of its own weight when released from 5°–10° off center; if not check for:

a. Steering bearings too tight;
b. Bent steering stem;
c. Worn races or balls.

7. Install the front fender, front wheel, and handlebars. Route the cables and controls as illustrated.

REAR SHOCKS (STANDARD)

Removal and Installation

1. The shock absorbers can be removed after their upper and lower fasteners are taken off.
2. To remove the spring, first set the cam ring on the softest position. Then compress the spring by hand or with the aid of special tool No. 07959-3290000 and remove the spring retainers.
3. Measure the free length of the springs. They should be about 216 mm (8.5 in.) on 1969–1978 models, and 237 mm (9.5 in.) on 1979–1980 machines. Replace both if either measures less than this amount.
4. Check the springs for straightness. Replace them if tilt exceeds 2.5°.

REAR SHOCKS (AIR TYPE)

Removal and Installation

1. Remove the left side cover.
2. Remove the air valve cap. Disconnect the switch wire.
3. Remove the three-way joint mounting nut.
4. Disconnect the air hoses from the three-way joint.
5. Remove the upper and lower shock mounts and remove the shock.
6. Grease air fitting o-rings before installation to ensure a good seal.
7. Tighten shock mounts to 22–29 ft. lbs.

Disassembly

CAUTION: *Wear face and eye protection.*

1. Disconnect the air hose from the shock.
2. Remove the boot.
3. Remove the seal circlip and back-up plate. Drain off as much oil as possible.
4. Place the bottom mount in a soft-face vise. Replace the boot and hold the top of the shock by it. Apply compressed air to the air fitting to force out the seal.

CAUTION: *Do not use excessive air pressure. Take adequate precautions to prepare for fluid spillage. Do not hold the bottom of the shock.*

Assembly

1. Oil capacity is 365 cc (12.5 oz.) of ATF per shock.
2. Install the circlip with the sharp edge facing upwards.
3. Air pressure should be 28–64 psi.

SWING ARM (CHAIN DRIVE)

Inspection

1. Remove the muffler(s).
2. Remove the rear wheel, shock absorbers, and chain guard.
3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.
4. Check that the rear wheel mounting plates are parallel.
5. Grasp the legs of the swing arm and attempt to move it from side to side. Any noticeable side-play will indicate that the swing arm bushings need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

Removal and Installation

1. Proceed as above. Then remove the swing arm pivot bolt nut and pull the pivot bolt out from the right side.
2. Remove the swing arm by pulling it straight back.
3. The swing arm should be inspected for cracks or fractures, especially around the welds.

After removal of the swing arm, the dust seals and bushings can be replaced. This should be done every 10,000 miles or more often depending on how the machine is used, or if the bushings are worn (see "Inspection," above).

4. Remove the bushings, tapping them out with a hammer and punch. Once the bushings are removed, they should be replaced.
5. Lubricate new bushings with a good chassis grease. Press the bushings into the swing arm, then lubricate and install the swing arm collar.
6. Clean out the pivot bolt and ensure that all grease passages are clear. Install the swing arm on the machine. Grease and install the pivot bolt. After tightening the swing arm pivot bolt nut, move the swing arm up and down to ensure that movement is smooth and effortless.

SWING ARM (SHAFT DRIVE)

Removal

1. Remove the rear wheel.
2. Remove the lower shock mount bolts.
3. Disconnect the brake hose from the swing arm.
4. Remove the cotter pin and the rear brake caliper. Remove the final drive gear.
5. Remove the left swing arm pivot cap. Loosen the locknut and remove the swing arm pivot adjusting bolt.
6. Remove the right swing arm pivot cap and the pivot bolt.
7. Remove the swing arm.

Installation

1. Grease bearings and swing arm pivots before installation.
2. Tighten the pivot bolt to 36–51 ft. lbs. Tighten the adjusting bolts to 12–14 ft. lbs.
3. Check swing arm operation. Recheck adjusting bolt torque. Tighten locknut to 36–51 ft. lbs.

CHAIN FINAL DRIVE

Chain Inspection

The chain should be regularly inspected for wear and damage in the following manner:

1. Place the bike on the center stand and thoroughly lubricate the chain.
2. Measure the amount of slack at the middle of the chain run, and, if slack exceeds 1.5 in., adjust the chain. Refer to chapter 2.
3. Turn the wheel slowly and examine the chain for:
   a) damaged rollers
   b) loose pins,
   c) rusted links,
   d) binding or kinked links.

Replace the chain if the rollers are damaged or the pins are loose, or if rusted or binding links cannot be worked free with lubrication

Sprocket Inspection

Check the sprockets for broken or worn teeth. Worn sprocket teeth have a hooked, asymetrical appearance. If the side of the sprocket is worn, the indication is that the sprockets are misaligned. In any case of wear or damage, the sprocket should be replaced. Remember that worn sprockets can ruin a good chain, and vice versa. Do not hesitate to replace the chain and both sprockets, if need be, to avoid costly and dangerous chain failure.

Chain Removal and Installation

MASTER LINK CHAINS

The chain can be separated and pulled off the sprockets after the master link has been removed. Threading the chain back onto the countershaft sprocket is made easier if you have an old enough chain lying around that you can hook onto the chain on the bike as it is removed. Leave the old chain draped over the sprocket so that you can hook the good chain back onto it and pull it over the sprocket when you are ready to reinstall it. Be sure to install the master link clip with the closed end facing in the direction of forward rotation of the chain.

ENDLESS CHAINS

To remove the endless chain it is necessary to use a chain breaking tool. A heavy-duty chain breaker is available from Honda dealers, part No. 07062-30050. To break the chain using this tool:

1. Grind or file the pins of the link to be removed flush with the link side plate. Break the chain at the master link (identifiable by the depression in the pin centers).
2. Swing the pin seat backing plate on the chain breaker away from the pin seat and place one of the link rollers in the holding lugs of the tool.
3. Seat the main bolt against the side plate of the link and turn the link removal bolt in until the pin is driven out.
4. Place the other link roller in the holding lugs and repeat step 3.

To install a new master link (replacing the chain on the motorcycle):

1. Insert the master link through the ends of the chain so that the side plate is inside (closest to the wheel).
2. Place one of the master link rollers in the holding lugs of the tool with the pins facing the main bolt.
3. Push the pin seat knob in until it contacts the pin and swing the pin seat backing plate over to lock the pin seat in position.
4. Place the master link side plate in the guide block, so that the stamped letters or numbers on the plate face the surface of the

Chassis Torque Specifications

guide block (facing out when installed on the chain).

5. Back out the link removal bolt until it is behind the nose of the main bolt.

CAUTION: *The link removal bolt will be damaged if it is allowed to protrude beyond the nose of the main bolt.*

6. Place the guide block in the tool with the master link side plate against the pins. Make sure that the pins are aligned with the holes in the side plate.

7. Turn in the main bolt until the pins pass through the plate and seat against the recess in the guide block.

8. Reposition the guide block so that the staking die faces the pin and the protruding shoulder of the guide block is below the side plate.

9. Turn in the main bolt until the staking die contacts the pin. Check to make sure that the die is centered across the pin.

10. Turn in the main bolt an additional ¾ turn to stake the pin. Repeat steps 8–10 for the other master link pin. Examine both pins to make sure that they are properly staked.

CAUTION: *The main bolt must be turned no more or no less than ¾ turn. Less than ¾ turn will not secure the side plate properly, and more than ¾ turn may crack the pin.*

Sprocket Removal and Installation

To gain access to the engine sprocket it is only necessary to remove the left-side rear crankcase cover. The sprocket can be unbolted after the locktabs (if applicable) are bent back. Loosen or remove the chain and then remove the sprocket.

Rear Hub Damper Service

1. Remove the rear wheel assembly and withdraw the axle.

2. Remove the sprocket and final drive flange. The sprocket may be separated from the flange by bending down the locktabs and removing the sprocket nuts.

3. Replace worn or cracked damper rubbers. When refitting damper rubbers, lubricate them thoroughly with a soapy solution or dishwashing liquid to facilitate insertion into the hub.

GENERAL INFORMATION

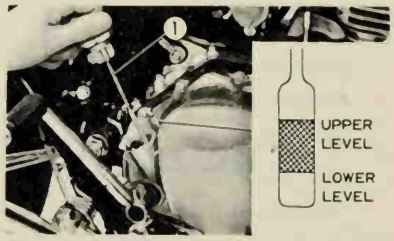
SERIAL NUMBER LOCATION

In order to prevent possible confusion when purchasing parts, always refer to the engine and frame serial numbers. The frame number is stamped on the left side of the steering lug, while the engine number is behind the cylinders on the top left side of the crankcase.

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in the "General Information" section.*

LUBRICATION

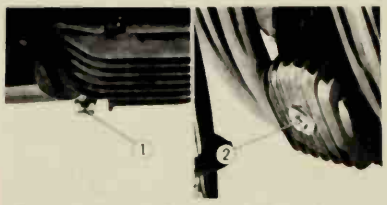


Motor Oil

For use in all temperatures, Honda recommends SAE 10W-40 motor oil service rating "SE" or "SF."

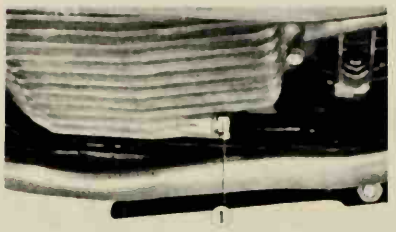
Straight grades can also be used according to ambient air temperatures as given in the "Recommended Lubricants" chart at the end of this section.

Checking Oil Level



1. Allow the engine to run for several minutes before checking the oil level.
2. With the machine parked on the center stand on level ground, and with the engine shut off, unscrew and remove the dipstick and wipe it clean. Reinsert the dipstick, allowing it to rest on the threads of its hole. Do not screw it in. Remove it and check the level. It should be between the upper and lower level marks inscribed on the dipstick. If it is at or near the lower mark, add enough oil to bring the level up to the upper mark, but do not overfill the crankcase.

Dipstick upper and lower level marks



Changing Oil

1. The recommended oil change interval is 1,500 miles, or three months, whichever comes first.
2. Oil should be changed when the engine is warm. This ensures more complete draining and makes it more likely that the oil will carry off any particulate matter with it.
3. Remove the dipstick. Unscrew and remove the crankcase drain plug, allowing the oil to drain for several minutes into a suitable container. Kick the engine over several times with the kickstarter (ignition switched *off*) to remove any old oil remaining in the system.

Oil drain plug (1) and oil filter bolt (2) (350/400)

4. Check the condition of the drain plug gasket. Install the plug, and tighten it to about 25 ft lbs.

Oil drain plug (1) (500/550)

5. If the oil filter is to be replaced, refer to "Oil Filter," below.
6. SAE 10W-40 oil is recommended for all models and can be used at any temperature. If the average air temperature is above 59° F (15° C), SAE 20W-50 oil can also be used.

CB500K1-K2: 2120/83.5

7. Add about 3 qts of oil to the crankcase. Start the engine and allow it to run for several minutes, then shut it off and check the oil level. Add oil, as necessary, to bring the level up to the upper mark on the dipstick. Crankcase capacities are as follows:

CB350/400	3.7 qts.
CB500/550/650	3.2 qts.

Oil Filter

1. The oil filter element should be replaced at every other oil change, or at 3000 mile/6 month intervals.

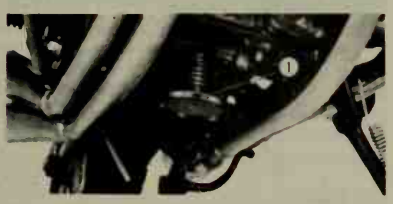
Oil filter assembly

1. Oil filter cover
2. O-ring
3. Spring
4. Washer
5. Oil filter element
6. Oil filter center bolt

2. After removing the crankcase drain plug and allowing the oil to run off, remove the oil filter housing bolt, placing a drip pan or suitable substitute beneath the housing to catch any oil in the filter housing.

3. Take out the old filter, washer, and spring. Clean the housing. Check the condition of the housing O-ring.

4. Wipe off the mating surface on the crankcase with a clean rag. Oil the O-ring lightly with clean oil.



5. Slipping the filter housing bolt into place, fit the spring and washer, then the new filter element. Install the housing, tightening the housing bolt to 20–24 ft lbs.

CAUTION: *Do not overtighten the housing bolt. If this is done, it will not only be difficult to remove, but it may crack the housing in the area around the bolt hole. If the bolt is difficult to remove, be sure to inspect the housing closely around the bolt hold for small cracks.*

6. Add oil to the crankcase as outlined under "Changing Oil," above.

Filter Screen

1. All models are equipped with a filter screen in the sump which should be cleaned and inspected at 6,000-mile or 12-month intervals.

Oil strainer screen

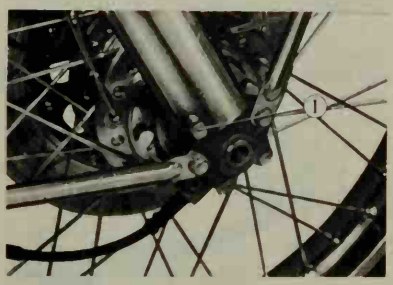
2. After draining the sump, unbolt and remove the oil pan.

3. Withdraw the screen from the oil pump, and clean it in a safe solvent, brushing off foreign matter if necessary. Inspect the screen mesh for holes, and replace it if any are noted.

When refitting the filter screen, align the slot in the strainer with the crankcase rib.

4. When installing the pan, a new gasket should be used. After refilling the system with oil, start the engine and check for leaks around the oil pan mating surface.

Front Forks



350/500

1. ATF is recommended for all forks. Special types of oil designed specifically for motorcycle forks can also be used, although care must be taken to flush the forks thoroughly when changing types or brands of fork fluid, since some may not be compatible with others.

Do not use gasoline to flush forks.

2. Fork oil should be changed every 6,000 miles or 12 months.

3. Place a container beneath one of the fork sliders and remove the drain plug. Pump

Fork slider drain plug (1)

the slider up and down until all the oil is expelled. Examine the plug gasket, then refit the plug. Repeat the procedure with the other slider.

4. Examine the drained oil. If it contains water or is exceptionally dirty, it may be that the fork gaitors or dust covers are damaged and allowing foreign matter to get past. This will also damage fork seals quickly. Check that the gaitors or dust covers are properly secured and replace them if cracked, ripped, or otherwise damaged.

5. Remove the handlebar clamp bolts and move the bars to one side or the other to allow access to the fork filler caps.

6. The fork filler caps are threaded into the fork tubes, and are also connected to the fork damper rod. Removal will be facilitated by first loosening the upper triple clamp pinch bolts. Next, compress the front forks either by placing a block beneath the front wheel, or by parking the machine on the side stand, rather than the center stand.

7. Remove *one* of the fork filler caps which should rise out of the fork tube if the forks are sufficiently compressed.

CAUTION: *Do not remove both filler caps simultaneously unless the front wheel is supported off the ground, or the forks will collapse.*

8. Add the proper grade and quantity of ATF to the fork tube. Capacities are:

350	105cc/3.6 oz.
500	145cc/4.9 oz.

9. Inspect the filler cap O-rings for condition. Oil them lightly before refitting the cap(s).

10. Allow the forks to extend so that the damper is drawn back into the fork tube. Secure the filler cap. Tighten the upper triple clamp pinch bolt.

Fork filler caps (1)

11. Repeat the procedure with the remaining fork leg.

12. Secure the handlebars, tightening the forwardmost bolts first.

13. After several miles of operation, check the area around the fork slider seals for leaks or seepage. Even a minimal amount would necessitate replacement of the seals. A coating of grime building up in this area over a period of time is also indicative of ineffective seals.

400/550/650 (Except Air Shocks)

1. ATF is recommended for all forks. Special types of oil designed specifically for motorcycle forks can also be used, although care must be taken to flush the forks thoroughly when changing types or brands of fork fluid, since some may not be compatible with others.

Do not use gasoline to flush forks.

2. Fork oil should be changed every 6,000 miles or 12 months.

3. Place a container beneath one of the fork sliders and remove the drain plug. Pump the slider up and down until all the oil is expelled. Examine the plug gasket, then refit the plug. Repeat the procedure with the other slider.

4. Examine the drained oil. If it contains water or is exceptionally dirty, it may be that the fork gaitors or dust covers are damaged and allowing foreign matter to get past. This will also damage fork seals quickly. Check that the gaitors or dust covers are properly secured and replace them if cracked, ripped, or otherwise damaged.

5. Support the front wheel off the ground by placing a scissors jack or similar device beneath the engine.

CAUTION: *Do not remove the fork filler caps without supporting the front wheel in this manner.*

6. Remove the handlebar clamp bolts and move the bars to one side or the other to allow access to the fork filler caps.

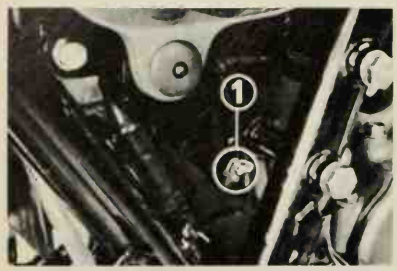
7. Loosen the upper triple clamp pinch bolts to facilitate removal of the filler caps. Remove the fork filler caps. The caps are under spring tension, so care should be exercised when removing them.

8. Add the proper grade and quantity of oil to each fork leg. For a routine oil change, these quantities are:

400/650	145–150 cc/4.8–4.9 oz.
550	170–175 cc/5.8–5.9 oz.

9. Inspect the filler cap O-rings for condition. Oil them lightly before refitting the caps. Install the caps and tighten them securely. Tighten the upper triple clamp pinch bolts.

10. Secure the handlebars, tightening the forwardmost bolts first.



11. After several miles of operation, check the area around the fork slider seals for leaks

or seepage. Even a minimal amount would necessitate replacement of the seals. A coating of grime building up in this area over a period of time is also indicative of ineffective seals.

Chassis Lubrication

1. The swing arm pivot is fitted with one or two grease nipples which should be lubricated with chassis grease every 3,000 miles. On most models the nipples are on the ends of the swing arm pivot shaft, while the latest designs have a single nipple in the middle of the swing arm.

2. Wheel and steering head bearings are

Swing arm grease nipple (1)

lubricated with bearing grease, the service interval being 12,000 miles or 24 months.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

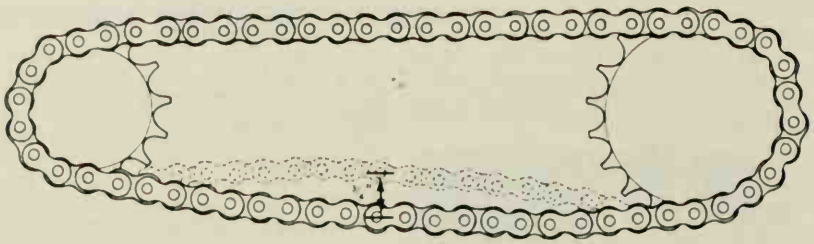
2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on the center stand so that the rear wheel is off the ground;

b. The transmission should be placed in neutral;

c. The chain should be clean and well-lubricated;

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably worn sprockets which should be replaced as soon as possible.



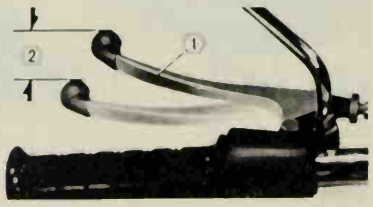
3. To adjust the chain, first back off the rear brake adjuster nut.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

5. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately corrected.

6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

7. Tighten the axle nut and adjuster bolt nuts and check the chain tension. The chain



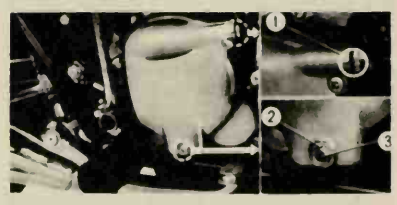
Chain slack should be measured at the middle of the lower run

tension should also be checked with the weight of a rider sitting on the motorcycle when it is off the center stand; the chain should still have at least ½ in. of free-play. Correct if necessary. After adjustment is correct, torque the axle nut to 60–72 ft lbs.

Fit a new cotter pin. Readjust the rear brake.

Clutch

1. Cable adjustment must always be maintained at the proper specification. If the cable has insufficient free-play, the clutch will slip and rapidly burn out. If it has too much play, the clutch will not compltely disengage, resulting in hard shifting and creeping at stops.



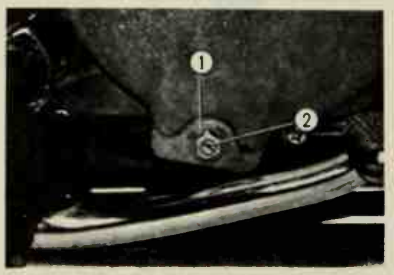
Measure free-play (2) at the end of the lever

2. Use the cable adjuster at the handlebar or engine to maintain the correct amount of cable slack. The clutch hand lever should be able to be moved 10–20 mm (0.4–0.8 in.) measured at the tip of the lever before the clutch begins to disengage.

If clutch operation is not satisfactory after making this adjustment, proceed as follows:

350/550 Models

1. Using the cable adjuster at the engine, align the clutch lever and the right crankcase index marks as illustrated.

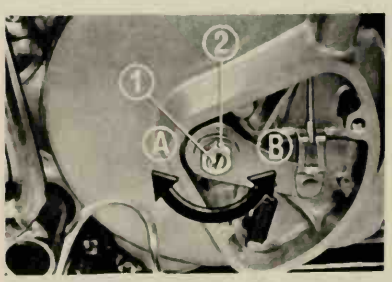


Line up the marks (1), loosen the locknut (2), and rotate the adjuster (3) (350)

Clutch lever alignment marks (550)

2. Loosen the clutch adjuster locknut. Turn the adjuster counterclockwise until resistance is felt, then back it off about ¼ turn and tighten the locknut.

3. Use the cable adjusters so that the hand lever has the prescribed amount of free-play.



Clutch adjuster locknut (1) and adjuster (2) (550)

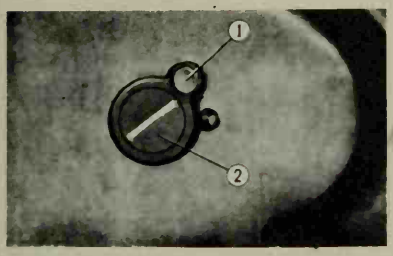
400 Models

1. Loosen the locknut, and screw the cable adjuster at the hand lever all of the way into the lever bracket.

2. Loosen the locknut, and screw the adjuster at the clutch housing all of the way into the housing to increase cable free-play to the maximum.

3. Remove the clutch cover from the clutch housing. Loosen the locknut on the clutch adjuster, and turn the adjuster in (clockwise) until a slight resistance is felt. From the point where resistance is first felt back the adjuster out (counterclockwise) ¼–½ turn, and tighten the locknut.

Clutch adjuster (1) and locknut (2) (400)



4. Using the cable adjuster at the clutch housing, adjust the cable so that there is about ¾ in. of free-play at the end of the hand lever. Use the adjuster at the hand lever to bring the cable free-play into specification.

500 Models

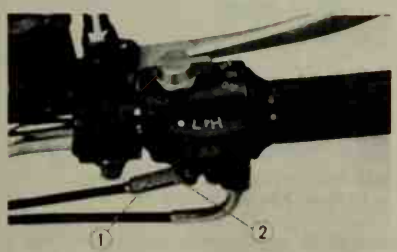
1. Loosen the locknut, and screw the cable adjuster at the hand lever all of the way into the lever bracket.

2. Loosen the locknut, and screw the adjuster at the engine into the housing to increase cable free-play to the maximum.

3. Loosen the clutch adjuster lockbolt and,

Clutch adjuster (2) and lockbolt (1)

using a large screwdriver, turn the adjuster clockwise until a slight resistance is felt. At this point, turn the adjusting screw counterclockwise approximately ⅛ in. and tighten the lockbolt.



4. Turn the cable adjuster at the engine out so that there is about ½ in. of free-play measured at the end of the lever, and tighten the locknut. Use the cable adjuster at the hand lever to bring the cable free-play into specification.

650 Models

1. Loosen the locknut on the cable adjuster at the engine and screw the adjuster all the way in to obtain maximum cable free-play.
2. Remove the clutch adjuster cover.
3. Loosen the clutch adjuster locknut. Turn the adjuster screw in (clockwise) until a slight resistance is felt, then back it off ¾ turn and hold it there while the locknut is secured.
4. Use the cable adjuster at the engine to give the proper amount of cable free-play.

Throttle Cable

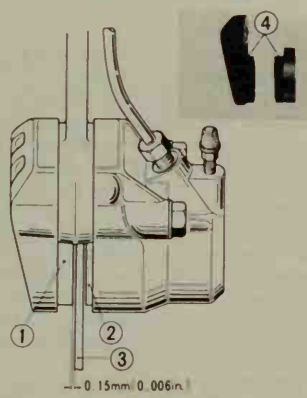
1. The throttle cable is fitted with an adjuster at the twist-grip. The twist-grip should be able to be rotated approximately 10–15° before the throttle slides begin to open. This is equivalent to about 2–4 mm (0.08–0.16 in.) of cable free-play.

Cable adjuster (1) and locknut (2) location

2. Use the cable adjuster at the handlebar to make and maintain this adjustment. To check that the cable has sufficient slack, start the engine and turn the forks slowly from lock-to-lock. Idle speed must not increase. If it does, it indicates that the cable has insufficient free-play, is incorrectly routed, or is binding at some point.

Front Brake (350–550)

The front disc brake needs no routine maintenance other than a periodic check of fluid level and pad wear. If the brakes drag or lack power, adjustment of the caliper may be necessary, an operation which should also be done when new pads are fitted.



Brake fluid level line (1)

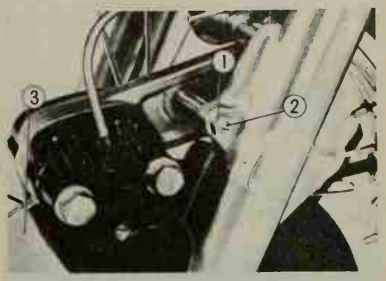
1. Position the front wheel so that it points straight ahead. After removing the master cylinder reservoir cap and diaphragm, check to see if the brake fluid level is up to the mark inscribed on the inside of the reservoir. Fluid level will drop slightly as the pads wear. If the fluid is below the level mark, add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and the cap, and tighten it securely.

CAUTION: *Do not use brake fluid from an old or unsealed container.*

2. Check the brake pads for wear and replace both of them if either is worn to the red limit line inscribed around the pads.

Replace the pads when worn to the red limit line (4)

1. Inner pad	3. Brake disc
2. Outer pad	4. Wear limit indicator



3. The brake lever should have 2–5 mm (0.08–0.2 in.) of free-play. If the lever has excessive travel and/or a mushy feel, the system should be bled.

Brake system service procedures such as pad replacement and bleeding are outlined in the "Chassis" section.

CALIPER ADJUSTMENT

The caliper must be adjusted whenever new pads are fitted, or if the brake seems to drag.

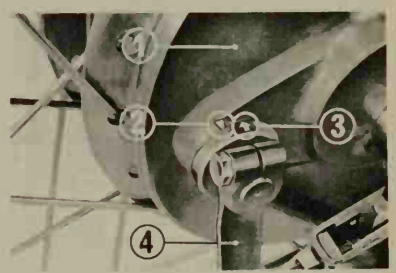
1. Raise the front wheel off the ground.
2. Clearance between the innermost pad and the brake disc should be 0.15 mm (0.006 in.).
3. To make the adjustment, loosen the adjusting screw locknut and turn the adjusting screw *counterclockwise* until the innermost pad contacts the disc. A slight drag on the front wheel will be noted when spinning the wheel.
4. Turn the adjusting screw *clockwise* until the wheel spins freely; then turn the adjusting screw ½ turn more in the same direction and tighten the locknut.
5. Check that the wheel turns freely without drag. Check for proper brake operation.

Brake caliper adjusting screw and locknut (1 and 2)

6. Brakes which drag constantly after application and which cannot be cured with proper caliper adjustment may be caused by sticking or seizure of the caliper bracket on its pivot. Free movement of the caliper is necessary for proper operation of the brake. This can be inhibited by dirt or other foreign matter between the pivot and caliper bracket. If the wheel will not turn freely after the brake is applied, try striking the caliper with the heel of your hand. If this frees the wheel, it is probable that the swinging bracket is becoming stuck. A penetrating fluid or parts lubricant applied to the bracket pivot will often remedy this problem.

Front Brake (650)

1. Turn the handlebars so that the brake fluid reservoir is parallel to the ground for an accurate check of the fluid level.
2. Maintain the fluid level between the upper and lower level marks.



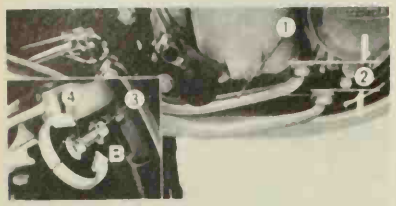
Fluid level will drop slightly as the pads wear. If too much is added, fitting new pads may necessitate draining some of the fluid.

Use DOT 3 brake fluid only. Do not use fluid from an old or unsealed container.

3. Check the pads for wear and replace both of them if either is worn to the red limit line visible through the inspection slot on top of the caliper.

Rear Brake

1. Brake lining wear on newer models can be determined by means of the wear indicator pointer fitted to the brake lever on the hub. If the pointer lines up with the red slash mark when the brake pedal is fully applied, the linings are worn as far as possible for effective braking and should now be replaced.

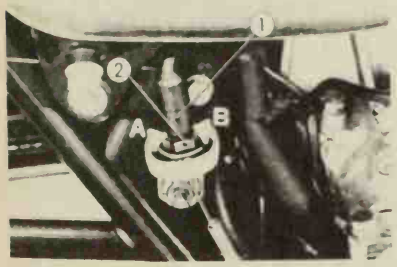


Brake wear indicator; replace the linings if the arrow and mark align when the brake is fully applied

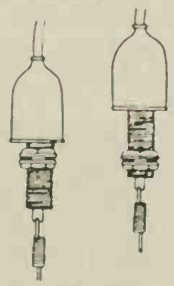
2. On older models, observe the angle formed by the brake lever on the hub and the brake rod when the brake is fully applied. When the lever and rod form an angle greater than 90°, the shoes should be checked for wear as they probably are worn to the point of needing replacement.
3. The rear brake should be adjusted so

that there is approximately 25 mm (1 in.) of free-play at the pedal before the linings contact the drum. Adjust by turning the hex nut on the brake rod. When adjustment has been made, be sure that the nut is seated properly on the brake lever pin. Also, check the operation of the brake light switch.

4. Brake pedal position may be adjusted to suit individual taste by backing off the brake adjusting nut, loosening the pedal height ad-



Rear brake pedal free-play (2). Pedal height can be adjusted by loosening the locknut (3) and rotating the adjusting bolt (4)



justing bolt locknut, and turning the bolt until pedal position is satisfactory. Thereafter, adjust pedal free-play and the brake light switch.

Brake Light Switches

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later.

Brake light switch. Turning the locknut in direction A will allow the light to come on sooner

Do not turn the switch itself for adjustment. Turn the locknuts only, or the wires will become twisted and may break.

Generally, the brake light should come on just as the linings contact the drum.

The front brake light switch is activated by fluid pressure and is not adjustable. If it fails, check the switch as outlined in "Electrical Systems," chapter 7.

Headlight Adjustment

1. Set the machine about 25 feet away from and perpendicular to a wall, preferably of a color which reflects light well.

The machine should be off the stand, and with a rider putting his weight on the machine as in operation.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

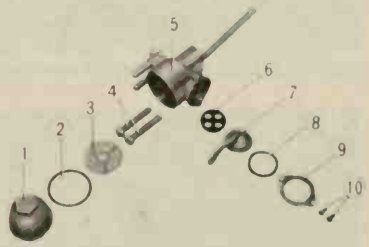
3. Vertical adjustment is made by loosening the two headlight shell mounting bolts slightly and pivoting the shell up or down.

4. Lateral adjustment is accomplished by means of the screw on the right-side of the headlight. Turning the screw clockwise will move the beam to the left, turning it counterclockwise will move it to the right.

FUEL SYSTEM

Fuel system maintenance involves cleaning the petcock fuel filter screen, cleaning or replacing the air cleaner, cleaning the carburetors, and cleaning the breather element (if fitted).

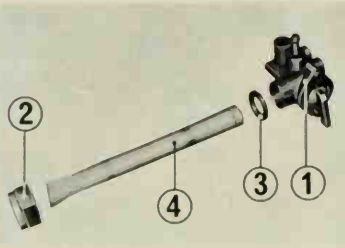
Normal service interval is 3,000 miles. Every 6,000 miles, the air cleaner element should be replaced.



Petcock

1. Two types of petcock are fitted, the change occurring on 1975 models.

2. On 1974 and earlier models, shut off the fuel, and unscrew and remove the sediment bowl. Take out the O-ring and fuel filter screen. Clean the bowl and filter screen in solvent and inspect the filter for any holes or other defects. If punctured, or so badly clogged that it cannot be properly cleaned, replace the screen. Inspect the O-ring for cuts or cracks. Reinstall the screen, O-ring, and sediment bowl. Be sure the fuel lines are properly secured with safety clips. Turn on the petcock and check for leaks before operation.

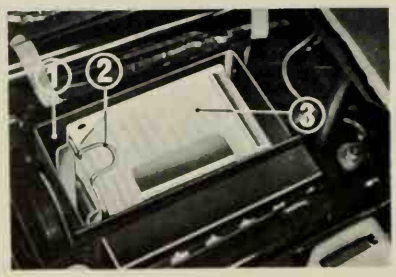


3. On 1975 and later models, the petcock filter screen is inside the gas tank. Shut off the fuel flow, and disconnect the lines from the petcock. Disconnect the fuel tank overflow line if fitted. Remove the gas tank and drain off the gas. Unscrew the securing nut and carefully take out the petcock. Remove the filter screen and securing nut from the petcock. Wash the filter in solvent to remove any foreign matter. Replace the filter element if it is badly clogged or if punctured. Check the condition of the gasket and replace it if it is crushed or nicked.

Installation is the reverse of removal. Be sure that the fuel lines are properly secured to

Petcock assembly

1. Sediment bowl	6. Gasket
2. O-ring	7. Lever
3. Fuel filter	8. Spring
4. 6 mm screws	9. Set plate
5. Petcock body	10. Screws



Petcock assembly (1975 and later). 1. petcock body, 2. nut, 3. o-ring, 4. filter screen

the petcock with safety clips. Check for leaks before operation.

Air Filter (350–550)

1. Lift the seat and remove the tool tray and air cleaner cover.

Case (1), set spring (2), filter element (3)

2. Pull out the spring clip. The filter element can now be withdrawn.

3. Tap the element lightly to remove any loose dirt, or use a reasonably soft brush to remove deposits. Blow out remaining dirt by applying compressed air to the inside of the element, if feasible.

4. Since cleaning paper elements is only partially effective, the unit should be replaced with a new one every 6,000 miles, or more often if used in a dusty environment.

Air Filter (650)

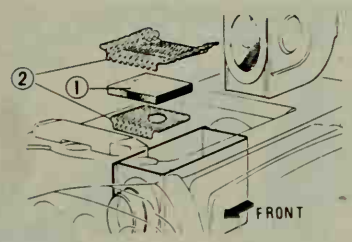
1. Remove the left side cover.

2. Remove the two air cleaner cover screws and take out the element.

3. Tap the element lightly to remove any loose dirt, or use a reasonably soft brush to remove deposits. Blow out remaining dirt with compressed air, if available.

4. Since cleaning dry paper elements in this fashion is only partially effective, the air cleaner element should be replaced with a new one every 6,000 miles, or more often if used in a dusty environment.

Breather Element



1. CB400 and 550 models are fitted with a crankcase rebreather system which directs crankcase fumes into the air cleaner box. A breather element separates water and oil from the air and allows them to drain off.

2. The breather element is accessible after removing the air cleaner element. Remove the element cover and take out the element.

3. Wash the element in a safe solvent and dry it thoroughly.

4. Check that the breather drain tube is clear. Squeeze the end to remove any oil or water, clean the inside of the breather case.

5. Install components in the reverse of removal.

Breather assembly (400)

6. On the CB650, a collection tube for condensed crankcase vapors is equipped with a transparent section. The plug should be removed and residue drained off when it is visible.

Carburetors

1. Cleaning of the carburetor float bowl and jets should be accomplished every 3,000 miles.

2. For this operation, removal of the carburetors from the motorcycle as an assembly is recommended. Refer to "Fuel Systems," chapter 6 for procedures.

Recommended Lubricants

Engine
General, all temperatures: SAE 10W-40, service rating "SE" or "SF"
Alternates: Above 59° F: SAE 30, SAE 20W-50
32° F to 59° F: SAE 20 or 20W
Below 32° F: SAE 10W

Front forks
ATF
SAE 10W-30
SAE 20W
SAE 30W

Disc brakes
DOT 3 standard brake fluid

Control cables
Light motor oil
Graphite-based lubricant
Molybdenum-disulphide-based lubricant

Tach, speedometer cables; throttle twist-grip
Light duty grease

Wheel and steering head bearings
Waterproof, medium-weight bearing grease

Grease fittings
Waterproof, medium-weight chassis grease

Drive chain
Lubricant developed specifically for motorcycle drive chains

Periodic Maintenance Intervals ①

Before each ride
Safety items
Operation of lights
Chain adjustment
Control cable adjustment

Weekly
Engine oil level
Tire pressure (check when cold)
Battery electrolyte level

Every 200 miles
Lubricate chain

Every 500 miles
Check tightness of critical fasteners

Every 1,500 miles/3 months
Change engine oil

Every 2,000 miles
Clean and lubricate chain

Every 3,000 miles/6 months
Change oil filter
Service all grease fittings
Clean breather element (if fitted)
Clean air filter element
Lubricate breaker cam felt
Clean fuel petcock screen
Lubricate all controls and cables
Check disc brake fluid level
Check brake pads or shoes for wear
Check operation of brake controls
Check clutch operation
Check condition of chain and sprockets
Check condition of fuel lines
Clean and check carburetor operation
Check spokes for tightness
Check swing arm bushings
Clean and gap or replace spark plugs
Clean and gap breaker points
Check ignition timing
Adjust valve clearance
Adjust cam chain tensioner

Every 6,000 miles/12 months
Clean oil filter screen
Change fork oil
Replace air filter element
Adjust steering head bearings

Every 12,000 miles/24 months
Flush and refill disc brake fluid
Repack wheel and steering head bearings

① Based on normal usage after initial service and break-in are completed

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in the "General Information" section.*

COMPRESSION TEST

1. A compression check should be made before each tune-up since this will provide a general idea of engine condition.

2. It is necessary to have a gauge with a flexible hose and the proper screw-in adapter (plug holes are 12 mm).

3. The engine should be at operating temperature when checking compression.

4. Remove all of the spark plugs and fit the gauge to one of the plug holes.

5. Close the choke and hold the throttle wide open while spinning the engine with the starter motor. Note the compression reading and repeat the test with the remaining cylinders.

6. Compression may vary according to gauge tolerance and several other factors. However, it should normally be between 140 and 170 psi. All cylinders must be within 15 psi of this range and of each other.

CAM CHAIN ADJUSTMENT

CB650

1. Remove the pulser generator cover (right side).

2. Be sure that the ignition is *off* and the transmission is in neutral.

3. Loosen the cam chain tensioner locknut located between cylinders Nos. 2 & 3 at the rear of the cylinder block.

4. Slowly turn the engine over in the normal direction of rotation (clockwise viewed from the right side of the engine) using a wrench on the crankshaft special nut. While doing this, retighten the tensioner locknut. Chain tension will be set automatically.

Other Models

1. Raise the seat, disconnect the fuel lines, and remove the gas tank.

2. Remove the points cover. Remove the valve adjuster caps from the No. 1 (left outside) cylinder, and remove all four spark plugs to make it easier to turn the engine over.

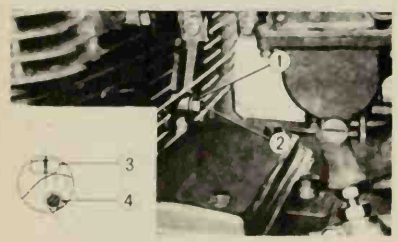
② CB500: 26/34
CB500K1-K2: 29/34
③ CB550K: 150–155/5.1–5.2
CB550F: 145–150/4.8–4.9

3. Using a wrench on the special nut provided for this purpose on the end of the breaker cam shaft, turn the engine over in the normal direction of rotation (clockwise as viewed from the right side) until the "T" (top dead center) mark for cylinders Nos. 1 and 4 ("1.4") aligns with the timing index mark.



Cam chain locknut (1) and tensioner bolt (2) (350/400)

4. Check that there is clearance at both valves for the No. 1 cylinder. If not, turn the crankshaft one complete revolution (360°) until the marks again align, and check the valves. To be effective, the chain adjustment must be performed when the No. 1 cylinder is on the compression stroke.

5. After the crankshaft has been properly positioned, continue to turn it clockwise until the spring peg on the timing advancer is just to the right of the timing index mark. In this position, cylinders 1 and 4 will be at 15° ATDC (after top dead center) and the adjustment can be performed.

CAUTION: *Do not rotate the crankshaft counterclockwise* (opposite the direction of normal rotation) *if you have turned it too far. Instead, rotate it clockwise through two revolutions so that the No. 1 piston will again be on the compression stroke and you can position the spring peg just to the right of the timing mark without having to turn the crankshaft back. Otherwise all of the slack may not be taken out of the chain.*

6. 350/400: The cam chain adjuster is located on the front of the engine. After positioning the engine as outlined above, loosen the locknut and back out the adjuster bolt until you can turn it with your fingers. At this point the bolt has released pressure on the

Cam chain adjuster (500)

1. Locknut
2. Adjuster
3. Timing mark
4. Spring peg

tensioner rod which has moved in automatically to take up the slack. Tighten the bolt to 5.9–7.2 ft lbs, then tighten the locknut.

7. 500/550: After positioning the crankshaft as outlined above, loosen the tensioner locknut and the proper chain tension will be obtained automatically. Tighten the locknut.

VALVE ADJUSTMENT

NOTE: *Valves must be adjusted when the engine is* cold.

In the following procedure, the cylinders are numbered 1 through 4, going from left to right from the point of view of a rider sitting on the machine. The firing order is 1-2-4-3.

1. Disconnect the fuel lines from the petcock, raise the seat, and remove the gas tank.

2. Unscrew and remove the valve adjuster caps from each cylinder. On the CB650, remove the adjustment covers and the breather cover. Remove the breaker points or pulser generator cover (right side). Remove the spark plugs.

3. Using a wrench on the special nut on the end of the crankshaft, turn the engine over in the normal direction of rotation (clockwise) and observe the valves of the No. 1 (left outside) cylinder. When the intake valve opens and then closes, the piston is approaching top dead center (TDC) on the compression stroke. Continue to turn the crankshaft slowly while observing the timing marks on the timing advancer. When the "T" 1.4 mark aligns with the index mark, check for clearance at both valves for the No. 1 cylinder. If there is clearance here, the crankshaft is properly positioned with the No. 1 cylinder at TDC on the compression stroke, and the valves can be adjusted according to the following procedure. If there is not clearance at both valves, the piston is at TDC on the *exhaust* stroke and the engine must be turned through one complete revolution until the "T" 1.4 mark again comes into alignment.

Rotate the engine with a wrench on the special nut (1) until the "T1.4" mark (2) and the index mark (3) line up

4. When the engine is properly set up as outlined in step 3, half the valves can be adjusted. These are the valves identified as "A" in the following chart:

(Looking down on the engine, from the rider's position.)

	Right side			
	No. 1 Cyl	*No. 2 Cyl*	*No. 3 Cyl*	*No. 4 Cyl*
Exhaust Valves	A	A	B	B
Intake Valves	A	B	A	B

5. Valve clearances are as follows:

	350 400	*500/550/650*
Intake (mm/in.)	0.05/0.002	0.05/0.002
Exhaust (mm/in.)	0.05/0.002	0.08/0.003

The clearances are measured between the valve stem and the adjusting screw. If the valve clearance is correct, a feeler gauge blade of this thickness will be a light slip fit. That is, there should be some resistance when pulling the blade through the valve, but not a considerable amount.

6. If the clearance is too large or too small,

Valve adjustment

loosen the valve adjuster locknut and turn the adjuster so that a slip fit is obtained. Hold the adjuster in position and tighten the locknut securely (350/400: 5–8 ft. lbs.; 500/550/650: 8–11 ft. lbs.). Recheck clearance after tightening the nut.

7. After all of the "A" valves are adjusted, turn the crankshaft one complete revolution (360°) until the "T" 1.4 mark again aligns with the index mark. In this position, the No. 4 (right outside) cylinder should be at TDC on the compression stroke (check for clearance at both valves) and the valves marked "B" can now be adjusted.

NOTE: *When the engine is at operating temperature, the valves should be very quiet. Ticking from properly adjusted valves is sometimes due to the valve stem becoming indented by the valve adjuster screw. This should be confined to older machines, since the valve ends are stellite-coated. Indentations on the valve stem will give a false feeler gauge reading: the clearance will be too large. Valves can be checked by visual inspection by unscrewing the adjuster.*

While more annoying than harmful, the only safe remedy for this situation is replacement of the valves.

CONTACT BREAKER POINTS

Location

The points and condensers are located on the right end of the crankshaft beneath the chromed points cover. The timing advance mechanism is fitted onto the crankshaft behind the breaker point base plate.

Replacement

1. Points sets are available complete with condensers already mounted on the breaker plate. Removal is accomplished by removing the small-6 mm bolt on the end of the breaker cam and taking off the large nut used to turn the engine over. This large nut is keyed to its shaft, not threaded. Next, disconnect the primary wires at the connectors. Carefully pull the wires through, noting the proper routing. Remove the three screws which secure the breaker plate. When the new plate is fitted, position it so that the securing screws are approximately centered in their slots, and adjust the point gaps and the ignition timing.

2. If the points are purchased separately, disconnect the primary wire at each point set, remove the securing screw, and remove the old points.

When installing new points, note that the

proper installation of the insulating washers at the primary terminal is critical. If improperly installed, no spark will occur. There is a small insulating tube which fits around the terminal bolt and two insulating washers, one immediately on either side of the terminal bracket. All connectors (condenser, primary wire, points spring) are made on the outer sides of three washers (i.e., no connector must touch the bracket, which is a ground).

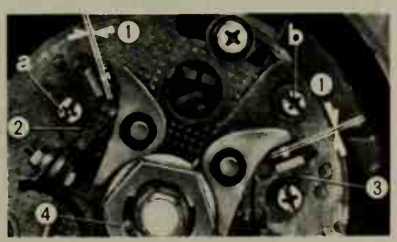
3. New points may have a protective coating on the contact surfaces to prevent oxidation. Clean off these surfaces with a non-oily solvent before attempting to start the machine.

4. If the motorcycle will not start immediately after installation of new points, check that the primary wire connections are tight, that the insulating washers at the primary terminal are properly installed, and that the contact surfaces are thoroughly cleaned.

5. Condensers are easily replaced after disconnecting the lead at the primary terminal and removing the screw which secures the condenser to the base plate.

Gapping

FEELER GAUGE METHOD



Periodic gapping is necessary to compensate for erosion of the contact surfaces due to electrical arcing and for wear of the fiber heel. As the heel wears, the points will open later relative to the rotation of the crankshaft, thus retarding the timing slightly.

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the points cover.

2. Using the special nut, turn the engine over until one of the two sets of points is fully open.

3. With the proper feeler gauge blade, check the gap. The proper specification is 0.3–0.4 mm (0.012–0.016 in.), and the blade should be a slip fit between the points if the gap is correct.

Loosen screws "a" and "b" to adjust point gap (1)

4. If adjustment is necessary, loosen the screw which secures the point set to its plate, and use a small screwdriver at the pry point provided to adjust the gap.

CAUTION: *Loosen the screw just enough to allow the points to be moved. If loosened too much, the points will snap shut instead of holding the gap.*

5. Tighten the screw and recheck the gap. It may change slightly when the screw is tightened.

6. Repeat the procedure with the remaining points set. Try to adjust both sets so that the feeler gauge blade has the same "feel" in both sets. This will help to ensure accurate timing.

7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the points should then be replaced.

DWELL METER METHOD

Point gap can also be adjusted with the aid of a dwell meter if one is available. "Dwell" is the amount of time the points are closed relative to crankshaft revolution and is expressed in degrees.

The adjustment is made with the engine idling, the meter connections being: positive lead to the primary wire terminal, and negative lead to the engine (ground).

With the meter set to the "8 cylinder" range, the proper dwell specification will be 23.75°; if set to the "4 cylinder scale, it will be 47.5°.

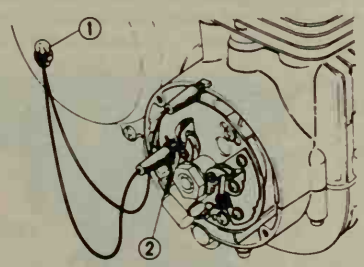
Increasing the point gap will decrease the dwell reading, and vice-versa.

Lubrication

1. On all models it is necessary to occasionally lubricate the cam follower fiber heel and the pivot point of the contact breaker. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.

2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.

3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.



4. The lubricating wick should be adjusted so that it just contacts the breaker cam.

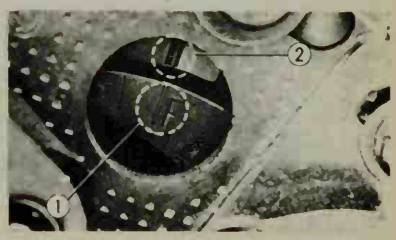
BREAKER POINT IGNITION TIMING

The timing advance mechanism behind the breaker plate is fitted with marks which indicate piston position when they are aligned with the stationary timing mark (visible through the inspection hole in the breaker plate). There are two sets of marks, identified 1.4 and 2.3 to indicate which cylinders they represent.

The timing marks on the advance mechanism are interpreted as follows: "T" indicates top dead center, "F" is the fixed advanced firing point, which is when the plug fires before the automatic timing advancer comes into play and is about 10° BTDC. An additional pair of marks indicates the full advance firing point, which is 33°–36° BTDC above 2500 rpm.

Observing the breaker plate, note that the points set on the left are marked "1.4." They control the timing for those two cylinders, and are secured to the large base plate. The righthand points, marked "2.3," are mounted on a smaller moveable plate. Therefore, cylinders 1 and 4 are set first, and the timing for this pair is adjusted by rotating the entire base plate. Obviously, this will affect the timing of the remaining cylinders. The latter are adjusted, if necessary, by moving only the points themselves as they have slotted fittings for this purpose.

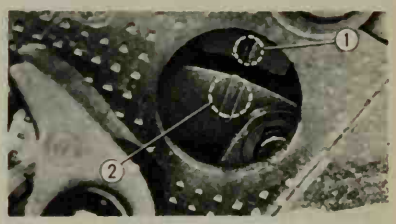
Ignition timing setup with test light (1) connected to the breaker points (2)



Dynamic Timing

1. Clean and gap both sets of points as described previously.

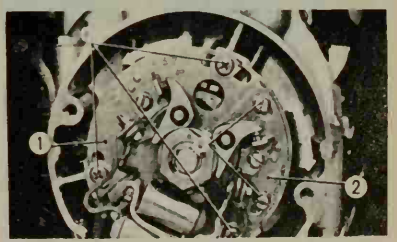
2. Hook up the strobe light according to the directions of the light's manufacturer to pick up the impulses from the No. 1 (left outside) cylinder.



3. Start the engine and adjust the idle, if necessary, to the recommended idle speed.

4. Aim the light at the timing marks visible through the inspection hole in the points base plate. At idle, the "F" mark should align with the timing index mark.

Before the timing advance mechanism comes into play, the "F" mark (1) should align with the timing index mark (2)



5. To check ignition timing at full advance, increase the engine speed until the motor is turning 2,500–3,000 rpm. At this point, the timing index mark should be between the two full advance marks scribed into the timing advance mechanism.

Full advanced timing marks (2) aligned with index mark (1)

6. If adjustment is necessary, carefully loosen the three base plate screws and rotate the plate so that the proper marks align at the specified rpm. Establishing this alignment at full advance is recommended. Tighten the base plate screws.

7. Repeat the procedure, this time having the strobe light pick up cylinder No. 2. If adjustment is necessary, loosen the two screws which secure points set 2.3 to its plate, and

Loosen screws "c" and rotate the breaker plate (1) to adjust the ignition timing for the Nos. 1 and 4 cylinders

use a small screwdriver at the pry point provided to move the set so that proper mark alignment is achieved. Tighten the screws.

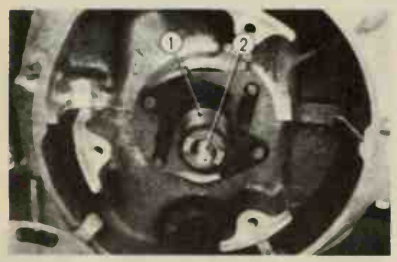
8. If it is not possible to achieve full advance alignment without moving the base plate or points set 2.3 all the way to the end of their range of allowable travel, it is possible that the points are either incorrectly gapped, or that they are worn to the point where they must be replaced.

Static Timing

1. Connect one of the test light or tester leads to the primary wire terminal for the points set "1.4." Ground the other lead to the engine.

2. If the test device is not self-powered, turn the ignition switch *on* and be sure the kill switch is in the "on" position as well.

3. Turn the engine over in the normal direction of rotation until the "F" mark for cylinders 1 and 4 align with the timing index mark. The test instrument should react at the instant these marks align, indicating that the points have opened. If they do not, loosen the three base plate screws and rotate the base plate so that the points just open when these timing marks are in alignment. Moving the base plate clockwise will retard the timing; counterclockwise will advance it.



Cylinders 1 and 4 are now correctly timed. Tighten the base plate screws and recheck.

4. Repeat the procedure with points set 2.3. If adjustment is necessary, loosen the two screws which secure these points to their mounting plate and use a small screwdriver at the pry point provided. Tighten the screws and recheck the timing.

Troubleshooting

1. If the static method is used, the reaction of the test light or meter should be positive when the points open. If the instrument seems to hesitate before indicating that the points are open, if may be because of defective condensers or dirty or pitted points surfaces.

2. If it is necessary to move the base plate or the points plate to the extreme end of the adjustment range to effect proper timing, the points or points heel is probably worn to the limit, and the set should be replaced.

Breaker cam (1) and shaft (2)

3. If the dynamic method is used, the various timing marks should hold their positions steadily at given rpms. If they seem to move erratically, check the condition of the timing advance mechanism behind the base plate. Check for weak or broken springs or stiff movement of the advancer weights. When the breaker cam is turned so that the weights move outwards, and then is released, it should return to the original position. If it does not, the springs are too weak and must be replaced. Try penetrating oil to ease movement of the mechanism if it is stiff. If this fails, replace the mechanism.

When installing the advancer unit, make sure that the pin is fitted into the locating hole.

TRANSISTOR IGNITION TIMING

Dynamic Timing

1. Remove the pulser generator cover (right side).

2. Connect a strobe light to cylinder No. 1 or No. 4.

3. Start the engine and allow it to idle at about 1,050 rpm while aiming the timing light through the cutout in the pulser generator plate.

4. At this engine speed, the "1.4 F-I" mark should line up with the stationary index mark.

5. At 2,725 rpm and higher, the full advance marks should align with the stationary timing mark.

6. If the marks do not align, loosen the three large phillips screws which secure the base plate, and rotate the plate until the proper alignment is achieved.

Static Timing

1. Rotate the crankshaft clockwise until the "1.4 S-F" mark aligns with the stationary timing mark.

2. At this point, the tooth on the rotor should align with the narrow projection of the 1.4 pulser generator (on the left).

3. If adjustment is necessary, loosen the three base plate screws and rotate the plate so that this alignment is made.

CARBURETORS

Carburetor adjustments to be made during a tune-up procedure include checking float level; idle speed, and mixture; carburetor synchronization; and travel limit adjustments.

Adjusting Float Level

1. Float level is a measure of the amount of gasoline which will be in the float bowls during operation. While it is a critical specification, it will not normally need readjustment once properly set. Float level, therefore, need not be checked at every tune-up, but should be attended to from time to time.

2. Remove the carburetors.

3. Remove the float bowls and the float bowl gaskets. With the carburetors positioned horizontally, lower the float until the float tang just touches the tip of the float needle and seats the needle. Float level is the measured distance from the bottom of the float to the float bowl mating surface.

NOTE: *A special float level gauge (part number 07144-99998) is available from Honda dealers which will facilitate this task.*

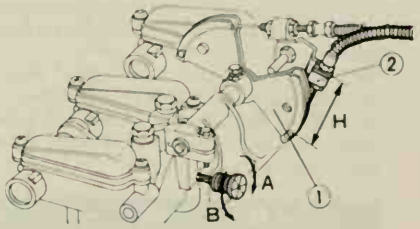
Adjusting float (1) height with the factory tool (2)

4. Compare the measured float level with the following standard values.

350/400	21 mm/0.83 in.
500/550	22 mm/0.87 in.
650	12.5 mm/0.50 in.

5. All carburetors must have the same float level. Measure all before changing any. Adjust, if necessary, by removing the float assembly and carefully bending the float arm tang. Bending the tang towards the carburetor body will increase the float level measurement and vice-versa.

6. Note that the measured float level will be inaccurate if the needle tip is worn, or if there is foreign matter on the needle seat.



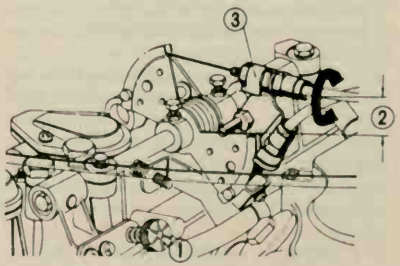
Synchronization and Idle Adjustment (350–550)

NOTE: *These adjustments must be made when the engine is at operating temperature. Other tune-up operations (valve adjustment, ignition timing, etc.) should be performed first.*

1. To gain access to the slide adjusting screws, raise the rear of the gas tank as far as possible and support it in this position. It may be necessary to fit longer fuel lines temporarily so that the tank can be raised higher. Be sure that there is an adequate fuel supply.

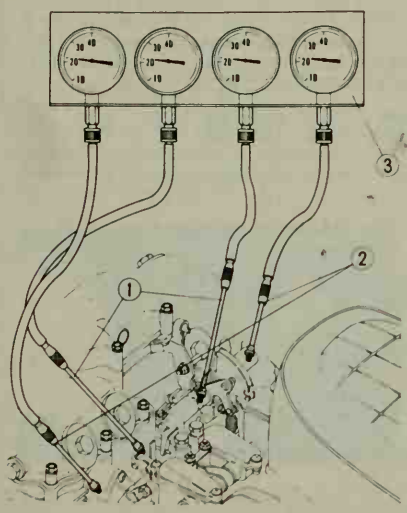
2. Turn each pilot screw in until it is lightly seated, then back each out *one* turn on 350, 500 and 550 machines, and *two* turns on 400s.

3. 350/400: Adjust the idle speed screw so that the measured distance from the cable holder to the cable fitting (see illustration) is 56 mm (2.21 in.).



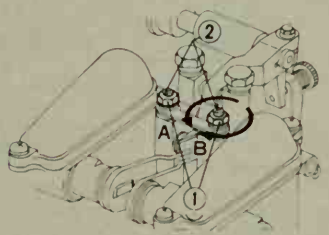
Adjust the idle speed screw so that "H" is 56 mm (2.21 in.) (350/400)

4. 500/550: Adjust the idle speed screw so that the measured distance between the cable holder and the throttle lever is 49 mm (1.94 in.). Refer to the illustration.



5. Install the vacuum gauge hoses to the intake manifolds.

6. Start the engine and check the vacuum readings for each cylinder. Each should be between 16–24 cm Hg and all cylinders must be within 3 cm Hg of each other.



7. To adjust the vacuum, loosen the locknut and turn the adjusting screw clockwise to increase the vacuum reading and coun-

Adjust the idle speed screw (1) so that distance (2) is 49 mm (1.94 in.)

Vacuum gauge connections

Vacuum adjusting screw locknuts (1) and screws (2)

terclockwise to decrease it. Try to maintain the same idle speed during adjustment.

NOTE: *Provision is made on some vacuum gauges for dampening needle movement if the needle tends to oscillate over a wide range. Do not overdampen the needles. A fluctuation of about one gradation on the scale is acceptable.*

8. After the desired settings have been obtained, snap the throttle open and shut a few times and recheck the vacuum readings after the engine has settled down. Readjust any carburetor(s) that show a lack of uniformity.

CAUTION: *Do not allow the engine to overheat by idling it for more than about five minutes while stationary. A household electric window fan can be used to provide a stream of air over the engine to keep it cool while making these adjustments.*

9. If the vacuum reading is less than 15 cm Hg for any carburetor, check the valve clearances, compression, ignition timing, and check for air leaks at the carburetor and intake manifold.

10. After all four carburetors have been synchronized, adjust the pilot screws to obtain the maximum idle speed consistent with smoothness. It should not be necessary to vary the pilot screws settings more than ¼ turn from the standard given settings (Step 2).

11. Adjust the idle speed to 1200 rpm (350, 400) or 1,000 rpm (500, 550) with the idle speed screw.

12. Remove the vacuum gauge tubes and tighten the intake manifold plugs securely.

Idle speed screw (1)

Synchronization and Idle Adjustment (650)

These adjustments should be made with the engine at operating temperature.

1. Park the motorcycle on the centerstand in a well-ventilated area. Be sure that the transmission is in neutral.

CAUTION: *Be sure that the work area is properly ventilated. Do not allow the engine to idle for more than a few minutes to avoid overheating the engine.*

2. Remove the side covers. Raise the seat. Remove the gas tank. Use long fuel lines to allow fuel flow to the carburetors while the tank is secured out of the way. Tank should be positioned higher than is normal.

3. Install the vacuum gauge(s).

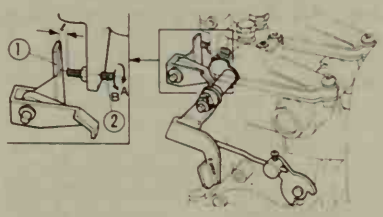
4. Remove the carburetor tops.

5. Start the engine and check vacuum readings at 1,050 rpm.

Difference between the carburetors should be 60 mmHg (2.4 in. Hg) or less.

6. Equalize the readings, if necessary, by loosening the locknuts and turning the adjusting screws.

Note that the No. 2 carburetor is not adjusted. It is the standard against which the other readings are to be compared.



7. After adjustment, gun the engine once or twice and recheck the vacuum readings.

8. Use the idle adjustment screw to set idle at 1,050 rpm.

Fast Idle Adjustment (350/400)

1. This adjustment is made after the carburetor slides have been synchronized. The engine should be at operating temperature.

2. Open (i.e. disengage) the choke lever fully and check the clearance between the link plate and the adjusting screw. It should be 0–0.3 mm (0–0.012 in.). Adjust the clearance, if necessary, by loosening the locknut and turning the adjusting screw.

Fast idle adjustment

3. Start the engine. Slowly raise and lower the choke lever until maximum idle speed is obtained. It should be 3,500–4,500 rpm. Readjust the screw if necessary so that this idle is obtained.

Fast Idle Adjustment (650)

NOTE: *This adjustment must be made when the engine is cold.*

1. Pull out the choke knob and start the engine. Fast idle speed should be 2,000 plus or minus 700 rpm.

2. To adjust, shut off the engine and remove the gas gank.

3. Turn the fast idle adjusting screw until it touches the cam surface.

4. Push the choke knob in and turn the adjusting screw in 2½ turns.

5. Recheck fast idle speed.

Choke Adjustment (650)

1. Remove the gas tank.

2. Check that the choke lever is fully closed when the knob is pulled all the way out.

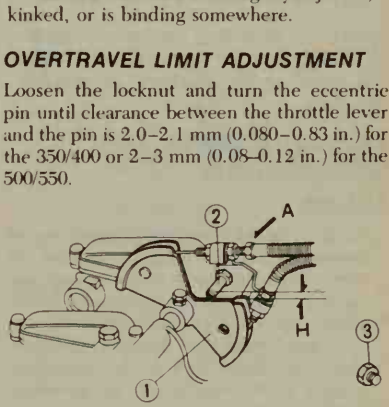
3. Make adjustments by loosening the choke cable clamp and moving the cable as required. Tighten the clamp holding the choke lever fully closed.

Throttle Cable Adjustment

PLAY ADJUSTMENT

1. Back off the cable adjuster at the handlebar to increase cable play. Leave a small amount of adjustment range so that final, small adjustments can be made.

After loosening the locknuts (2), rotate the adjuster (1) clockwise to increase play or counterclockwise (3) to decrease it



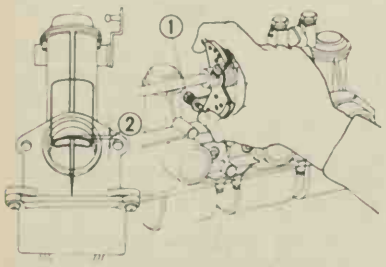
2. Loosen the cable adjuster locknut at the carburetors and turn the adjuster until there is about 10–15° of rotation of the twistgrip before the slides begin to lift. Retighten the locknut.

NOTE: *The throttle lever should hit the eccentric pin when the twistgrip is forced to the fully closed position. If the lever will not hit the pin, replace the return cable.*

3. Make any fine adjustments necessary with the adjuster at the twistgrip. With the engine idling, turn the forks slowly from lock-to-lock. Any variation in the idle speed indicates that the cable is too tightly adjusted, is kinked, or is binding somewhere.

OVERTRAVEL LIMIT ADJUSTMENT

Loosen the locknut and turn the eccentric pin until clearance between the throttle lever and the pin is 2.0–2.1 mm (0.080–0.83 in.) for the 350/400 or 2–3 mm (0.08–0.12 in.) for the 500/550.



After loosening the locknut (3), rotate the eccentric pin (2) until the clearance between the pin and lever (1) is correct

Tune-Up Specifications

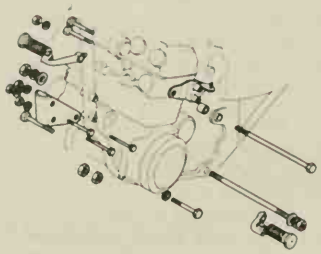
FULL THROTTLE LIMIT ADJUSTMENT

Adjust the throttle lever stop screw so that the carburetor slides can be pulled up 0–1.0 mm (0–0.04 in.) above the top of the carburetor bore before the throttle lever contacts the stop screw.

Adjust the stop screw (1) until the correct clearance (2) is arrived at

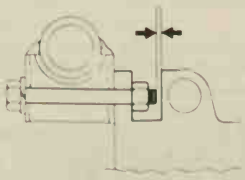
ENGINE AND TRANSMISSION



NOTE: *Common engine rebuilding techniques and procedures are explained in detail in the "General Information" section.*

ENGINE REMOVAL AND INSTALLATION

350/400



NOTE: *The following components can be serviced or replaced without removing the engine from the frame: cylinder head and cylinder head components, cylinder barrel, pistons, cam chain tensioner guide and slipper, clutch, gearshift linkage, alternator, and starter motor. Refer to the appropriate sections in this chapter for service procedures.*

1. Remove the drain plug and drain off the oil. Remove the oil filter.
2. Disconnect the fuel lines and remove the gas tank. Remove the footpegs (passenger's), and the exhaust system.
3. Remove the pinch-bolt and pull the gearshift lever off its shaft. Remove the rear portion of the left crankcase cover.

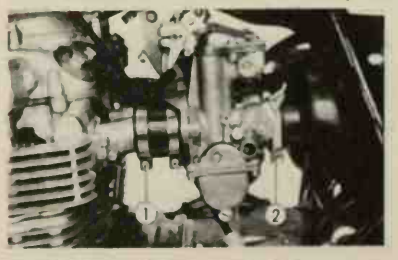
Engine mounting bolts (350/400)

4. Disconnect the final drive chain; alternately, unbolt and remove the engine sprocket.
5. Disconnect the electrical wires: spark plug caps, ignition coil wires, starter cable, alternator wires, and battery terminals.
6. Disconnect the throttle cables at the carburetor linkage. Disconnect the clutch cable at the engine. Remove the battery.
7. Remove the air cleaner. Remove the carburetors.

Front mounting bolt clearance is close; lockwasher must be in place

8. Remove the engine mounting bolts, mounting plates, and remove the engine from the frame.

a. Installation is the reverse of the above.



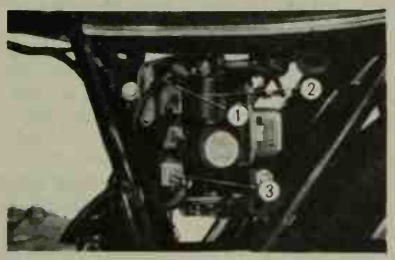
NOTE: Be sure to install the correct bolts at the lower front portion of the crankcase (10 x 75 mm). Be sure that the lockwasher is in place. Otherwise, it will be impossible to properly tighten the bolt.

b. Tighten the engine mounting bolts to 22–29 ft lbs.

500/550

NOTE: *The following components can be serviced or replaced without removing the engine from the frame: cylinder head and cylinder head components, cylinder barrel, pistons, cam chain tensioner, clutch, gearshift linkage, alternator, and starter motor. Refer to the appropriate sections in this chapter for service procedures.*

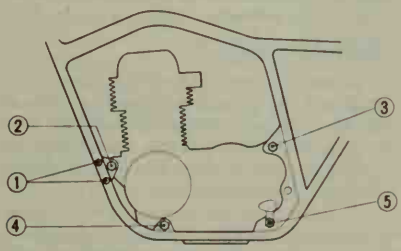
1. Turn the fuel tap off, disconnect the fuel lines, and remove the tank.
2. Unscrew the drain plug and filter housing bolt, and drain the oil.
3. Unbolt and remove all four exhaust pipes and mufflers.
4. Remove the wires from the spark plugs and disconnect the ground cable at the battery terminal.
5. Remove the 5 mm screw and withdraw the tachometer cable from the tachometer drive at the cylinder head.
6. Raise the seat and remove the air filter element. Unscrew the three bolts and remove the air filter housing.
7. Disconnect the throttle cables from the throttle linkage at the carburetors.
8. Loosen the air filter intake clamp and



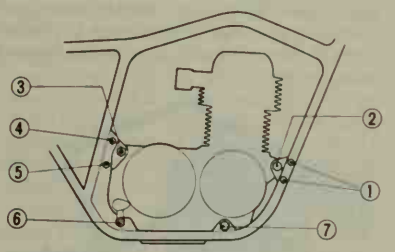
Carburetor mounting clamps (1 and 2)

intake manifold tube clamp at each carburetor. Remove the carburetors as a unit.

9. Disconnect the starter motor cable from the solenoid and the alternator output wire at the connector near the battery.



10. Remove the shift lever. Unbolt and remove the starter motor cover and left crankcase cover. Disconnect the clutch cable from the release mechanism.



Disconnect the starter cable (1) and the magnetic switch (2), then disconnect the generator leads (3)

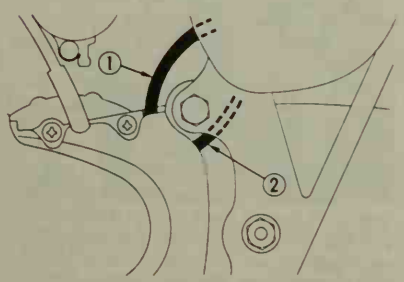
11. Remove the countershaft sprocket and drive chain. Disconnect the contact breaker point leads (yellow and blue) at the connectors.

12. Remove the engine mounting bolts and plates as illustrated. Raise the rear of the engine slightly and remove it from the right-side of the frame.

Left-side engine mounting points

Right-side engine mounting points

Installation is in reverse order of removal. The following points should be noted:



a. Tighten engine bolts to 22–29 ft lbs and mounting plate bolts to 13–18 ft lbs.

b. Do not neglect to connect the battery ground cable to the rear engine mount bolt as the bolt is installed.

c. Route the starter motor and alternator cables behind the frame tube.

d. Make sure that the muffler connecting clamps are in place on each pair of mufflers.

e. When installation is complete, refill the engine with oil. Adjust the clutch, drive chain, and carburetors.

Generator (1) and starter (2) cables correctly routed

650

NOTE: *The following components can be serviced or replaced without removing the engine from the frame: cylinder head, cylinders, pistons, cam chain tensioner, clutch, gearshift linkage, alternator, and starter motor.*

1. Drain the engine oil.

2. Remove the gas tank and the two side covers.

3. Disconnect the starter cable at the solenoid. Disconnect the ignition wiring coupler.

4. Disconnect the crankcase breather tube from the cover.

5. Remove the carburetor assembly.

6. Disconnect the tach cable from the head. Disconnect the spark plug caps.

7. Disconnect the clutch cable at the engine. Remove the rear brake pedal.

8. Remove the right side rider's footpeg. Remove the brakelight switch.

9. Remove the exhaust system complete.

10. Disconnect the alternator, neutral, and oil pressure wires at the couplers.

11. Remove the gearshift lever. Remove the left rear crankcase cover.

12. Loosen the rear axle nut, back the adjusting bolts off and push the wheel forward as far as possible. Unbolt and remove the engine sprocket and chain.

13. Remove the oil filter.

14. Place a jack beneath the engine to take the stress of the mounting bolts and remove the mounting bolts and engine bracket bolts. Remove the engine from the right side of the frame.

15. Installation is the reverse of removal. Check that mounting bolt torque is correct:

8 mm flange bolt/nut: 19–23 ft. lbs.
10 mm flange bolt/nut: 22–29 ft. lbs.
12 mm flange bolt/nut: 58–72 ft. lbs.

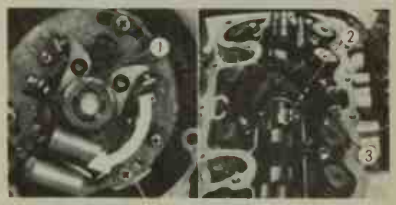
TOP END

NOTE: *Specifications not given in the following text may be found in the "Engine Specifications" charts at the end of this section.*

Cylinder Head Removal

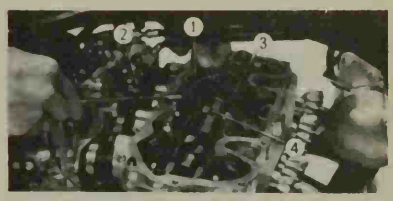
350/400

1. Remove the fuel tank, ignition coils, and breather cover, then disconnect the tachometer cable at the cylinder head.



2. Remove the eight tappet access caps, loosen the rocker arm adjusting screws, and remove the cylinder head cover. Remove the rocker arm shafts from the cover by removing the cap nuts, screwing a 10 mm (1.25 mm pitch) bolt into the shaft, and pulling it out. Mark each shaft and rocker arm for location.

3. Remove the exhaust system, spark plugs, and cam chain tensioner holder, then remove the tensioner holder and slipper.

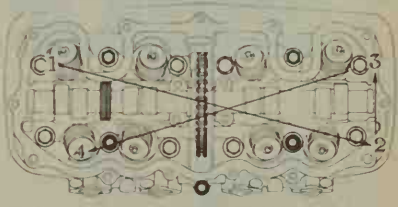


Removing a rocker arm shaft (1) with a puller bolt (2)

4. Remove the point cover, then rotate the crankshaft, by means of a suitable wrench on the special nut, until one of the cam sprocket bolts is vertical to the cylinder head,

Use the special nut (1) to rotate the crankshaft until the cam sprocket mounting bolts (2) are positioned as shown (350/400)

Lift the chain (1) off the sprocket (3) with a screwdriver (2) before removing the cam (4) (350/400)



and remove the bolt. Rotate the crankshaft 180° and remove the remaining sprocket bolt.

5. Lift the cam chain to avoid scratching the camshaft, then slip the camshaft out from the right.

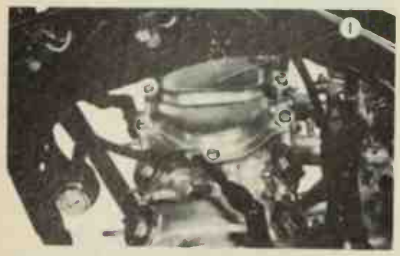
NOTE: *Loop a piece of wire around the chain to prevent it from falling into the crankcase.*

6. Remove the air cleaner element, loosen the air cleaner chamber retaining screw, and remove the carburetor assembly.

7. Remove the cylinder head securing bolts in a crisscross pattern as illustrated, remove the cam chain guide, and lift off the cylinder head, striking it with a soft mallet to loosen it if necessary.

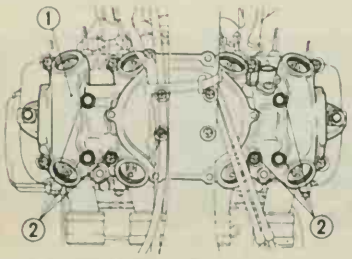
Head bolt loosening sequence (350/400)

500/550



1. Turn the fuel tap off and disconnect the fuel lines. Remove the fuel tank.

2. Unbolt and remove all four exhaust pipes and mufflers.



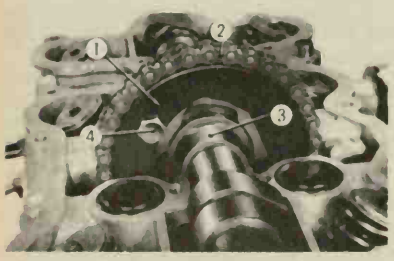
3. Disconnect the tachometer cable from the tachometer drive at the cylinder head.

4. Remove the wires from the spark plugs.

Take out the six screws and remove the breather cover.

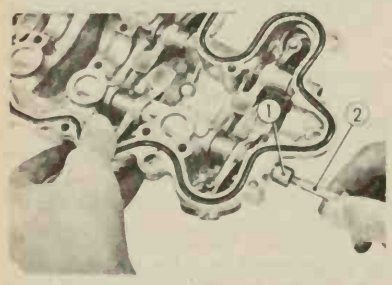
Breather cover (1) mounting screw location (500 and 550)

Keep the copper washers (2) separate for reinstallation when installing the cover (1) (500 and 550)



5. Remove the valve adjuster access caps, the left and right sidecovers, and the cover set plate. Gradually and uniformly (to prevent distortion) loosen the 12 screws and six bolts which secure the camshaft cover.

6. Loosen the adjuster locknut on the cam chain adjuster and turn the screw fully clockwise (about ¼ turn), then retighten the locknut. In this position, the cam chain is relieved of tension.



7. Remove the two camshaft sprocket mounting bolts and carefully withdraw the camshaft through the sprocket towards the right-side of the engine. Lift off the cam chain and remove the sprocket.

8. Remove the carburetors and unscrew the cam chain tensioner mounting bolts. The 12 cylinder head nuts and two flange bolts can now be removed and the cylinder head can be lifted off the engine. It is important that the bolts and nuts are loosened gradually and evenly in a cross pattern.

9. To remove the rocker arms, remove the rocker arm shaft end bolts. Screw a 6 mm bolt into the shaft and pull it out. Mark each rocker arm and shaft for location after removal.

After unbolting the sprocket bolts (4) from the cam (3), loop a piece of wire around the chain (500 and 550) to secure it

Removing a rocker arm shaft (1) with a puller bolt (2)

650

1. Remove the gas tank. Disconnect the tach cable on the head. Disconnect the breather tube. Pull off the plug caps. Remove the spark plugs.

2. Remove the breather cover and the adjuster covers. Remove the carburetors and the exhaust system.

3. Gradually, and in a cross pattern, loosen and remove the head cover bolts. Remove the cover.

4. Remove the pulser generator cover. Use a wrench on the special nut to turn the engine over until one of the two camshaft sprocket bolts is accessible. Remove the bolt. Turn the engine over and remove the remaining bolt.

5. Move the sprocket off the shoulder of the cam. Loop a length of safety wire around the sprocket and chain to keep them from falling into the engine when the cam is removed. Detach the chain from the sprocket. Remove the camshaft.

6. Remove the cam chain tensioner set bolt. Remove the six rubber seals.

7. Remove the 14 cylinder head bolts. Remove the head.

8. Remove the head gasket. Note the location of dowel pins and O-rings which are fitted between the head and the cylinder block.

9. To remove the rocker arms, remove the rocker arm shaft cotter pin nuts. Drive the pins out. Remove the rocker arm shaft cap bolts.

10. Thread a 6 mm bolt into the rocker arm shaft and pull the shaft out.

Inspection

ALL MODELS

Cylinder Head

1. Clean any traces of gasket material from the cylinder head mating surface. Place a straightedge across the mating surface and check for warpage by attempting to slip a feeler gauge blade between the head and the straight edge. Standard head warpage is about 0.05 mm (0.002 in.) and maximum allowable warpage is 0.3 mm (0.012 in.). At this point the head should be milled to restore a flat mating surface.

2. Use a wire brush fitting on a power drill to decarbonize the combustion chambers. The valves should be left in place when this is done, as it minimizes the chance of causing damage to the valve seats.

Camshaft

1. Check the condition of the cam bearings in the head and the cylinder head cover. Bearing surfaces must be smooth and free of scoring or marks of wear. If imperfections are noted, it is necessary to replace the head and the head cover.

2. Check the journal surfaces of the camshaft for similar signs of wear and replace the cam if the journal and surfaces are scored.

3. Measure the height of each cam lobe and compare your reading against the standard specification. Replace the camshaft if the lobe height is less than 28.00 mm (1.1024 in.) (intake and exhaust) on the 350/400, or 34.85 mm (1.3720 in.) (intake), 34.45 mm (1.3563 in.) (exhaust) on the 500/550. For the 650, service limits are 35.6 mm (1.40 in.) for the intake and 35.3 mm (1.39 in.) for the exhaust.

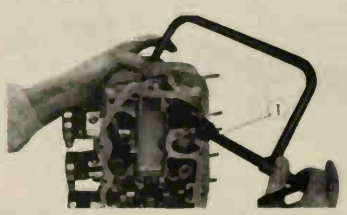
4. Visually inspect the lobes for pitting and replace the cam if this condition is noted.

5. Measure camshaft run-out, as illustrated, using a dial indicator. Maximum acceptable run-out is 0.1 mm (0.004 in.). Replace the cam if run-out exceeds this limit.

Rocker Arms

1. Check each rocker arm for pitting of the cam contact pad and replace any if damage is noted.

2. Check the fit of each rocker arm on its shaft. Rocker arm-to-shaft clearance can be as great as 0.1 mm (0.004 in.) (maximum).



3. Check each rocker arm shaft for scoring or wear of the rocker arm contact area. Replace any damage shaft. Inspect the rocker arm bores in like manner.

4. Check the shafts for a bent condition and replace them if so damaged. Check the arms and shafts for blue discoloration which is a sign of overheating usually caused by lack of lubrication; replace the arms and shafts if discolored in this manner.

Valve Assembly

Before removing the valves, check their sealing ability by pouring a small quantity of gasoline into each port and allowing the head to sit for about five minutes. If the valves are seating properly, leakage into the combustion chambers will be minimal.

1. To remove the valves, and install them properly, a suitable C-clamp is necessary. Compress the valve springs, and remove the split collars, retainers, springs, seals, and spring seats. Keep each assembly separate so that every piece can be installed in its original location. New valve seals must always be used on assembly.

Using a valve spring compresser (1) to remove the springs

Inspect the valves, guides, springs, and valve seats in the following manner.

2. If considerable mileage has been covered, the valve springs should be replaced as a matter of course. Always replace valve springs as a set.

3. Check valve spring free-length with a vernier caliper. Replace the springs as a set if any spring is shorter than the serviceable limit. For the 350/400 this is 27.0 mm (1.06 in.) for inner springs and 32.5 mm (1.28 in.) for outer springs. For the 500/550 this is 34.5 mm (1.35 in.) for inner springs and 39.0 mm (1.53 in.) for outer springs. For the 650, the specifications are 37.9 mm (1.49 in.) for the inner springs and 43.3 mm (1.70 in.) for the outer.

4. Each valve must be free to move up and down in its guide with little resistance. Any sticking or binding as the valve is moved in the guide will indicate that the valve stem or guide is in poor condition.

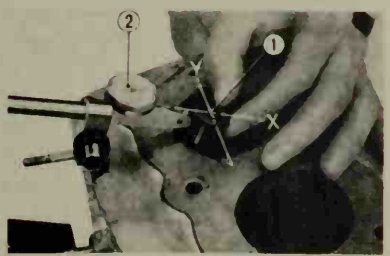
5. Inspect the valve, paying close attention to the edges of the valve head for pitting, burnt or broken edges, excessive carbon build-up, etc. A certain amount of carbon and lead deposits on the valve face and the top of the exhaust valve are inevitable. Heavy deposits should be carefully scraped off with a dull knife, or a wire wheel, and the valve finished up with very fine emery cloth.

Do not touch the valve seating area during these operations.

If the valve has burnt or broken edges, it must be replaced.

6. Check the end of the valve stem for indented wear caused by the valve adjuster. Although rare, it may occur after long mileage. Since an indentation here will make proper valve adjustments impossible, the valve should be replaced.

NOTE: *The tips and edges of the valves are stellite-coated. Machining for any reason is not recommended. In case of wear, replace the valve.*



7. Carbon deposits should not extend too far up along the valve stem. This would indicate a worn or cracked valve guide.

8. Wet, oily deposits on the back of the valve head is indicative of a worn guide or bad seal. Less severe wear to these components show up as brown oil stains on the valve stem.

9. Holding a valve in your fingers, spin it while observing the head. A wobble is indicative of a bent valve. If a dial gauge is available, check the run-out of the head. Replace the valve if run-out exceeds 0.05 mm (0.002 in.). Run-out is the total indicated dial gauge reading.

Attempt to rotate the valve by hand when it is fully inserted into the guide. If the valve will not rotate easily, or if it sticks as it is turned, it is probably bent.

10. Check valve-to-stem clearance and compare to the specification given. There are two ways of doing this. The first is to measure the diameter of the valve stem and the diameter of the inside of the guide and subtract the difference. Another way, somewhat easier, is to insert the valve into the guide, holding it about ½ in. off the seat, and check the total amount of allowable movement in two directions using a dial gauge. Maximum allowable clearances are as follows. For the 350/400, 0.3 mm (0.0118 in.) for both the intake and exhaust valves. For the 500/550/650, 0.08 mm (0.0031 in.) for the intake valves, and 0.10 mm (0.0039 in.) for the exhaust.

Checking valve-to-valve guide clearance with a dial indicator

If the measured clearances exceed these amounts, replace both valve and guide.

A quick check of the operational worthiness of a valve and guide can be accomplished by dipping the valve stem in oil and inserting it into its guide. Place a finger over the other end of the guide. Pull the valve a little way out of the guide and release it. The valve should be drawn back into the guide by suction if the components are inserviceable condition.

11. To remove valve guides, use a suitable drift.

Heating the head in an oven will facilitate removal and installation. Be sure the guides are fully seated.

After installing a guide, it must be reamed to the proper size. Use the proper Honda

Using a drift (1) to remove a valve guide

reamer for the application. Alternately, ream the valve guides to give clearances of 0.01–0.03 mm (0.0004–0.0012 in.) for the intake guides, and 0.03–0.05 (0.0012–0.0020 in.) for the exhaust guides.

12. After installing new guides, the valve seat should be recut and the valves lapped in. Valve seat angle is 45°. Valve seat width 0.7–1.5 mm (0.03–0.06 in.) for 350/400 models, and 1.0–1.5 mm (0.04–0.06 in.) for the 500/550/650.

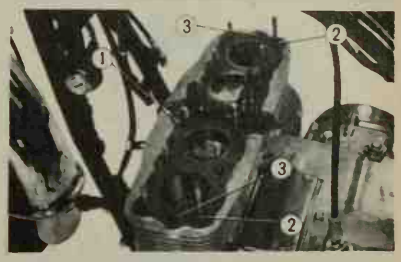
Cylinder Head Installation

ALL MODELS

1. Use new valve guide oil seals.

2. Valve springs may be progressively wound. Always install such springs so that the close coils are next to the head. The tops of the springs may be marked with paint.

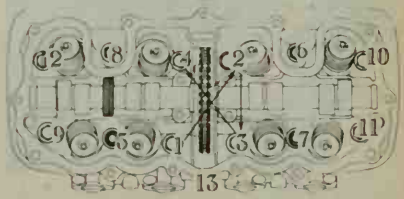
On 650s, rocker arm shaft cotter pins should be torqued to 7–10 ft. lbs.



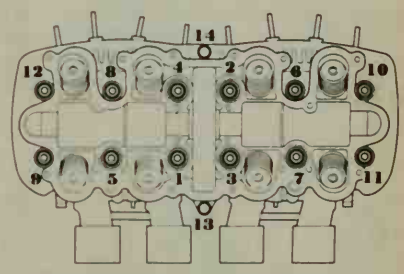
Progressively wound springs are installed with the close coils (arrows) towards the head

3. Install the cylinder head gasket, two dowel pins, and two O-rings on the cylinder. Mount the cylinder head on the cylinder while pulling the cam chain through the center of the head. Hold the chain from dropping down using a screwdriver as before. Tighten the head nuts gradually, in the sequence shown, to a final torque value of 14.5–16.5 ft. lbs. for all except the 650 which is 17–22 ft. lbs. After the nuts have been properly torqued, install and tighten the two 6 mm flange bolts (50/550/650) to 7–10 ft. lbs.

CAUTION: *Take care not to drop any hardware into the crankcase.*



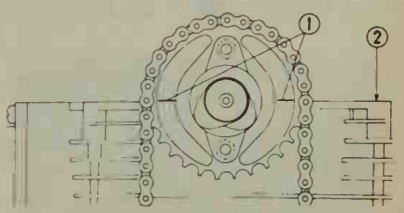
On the 650, loosen the cam chain tensioner locknut and pull up on the tensioner.



Gasket (1) dowel pin (2) and O-ring (3) locations

Tighten the locknut. This will give the cam chain maximum slack to make cam installation easier.

4. Hold the cam chain and cam chain sprocket together and install the camshaft

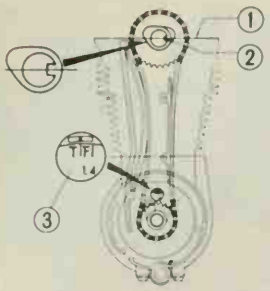


Head nut tightening sequence (350/400)

Head bolt tightening sequence (500/550/650)

through them from the right-side of the engine. The cam notch must be on the right. To set the valve timing properly, remove the ignition points cover and rotate the engine clockwise until the T(1.4) mark on the ignition advance unit aligns with the timing mark.

a. 350/400: Turn the cam sprocket until the lines on the sprocket are aligned with the cylinder head surface, as shown. Align the cam so it can be bolted to the sprocket.

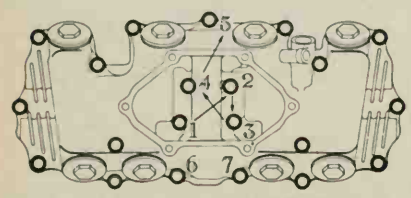


Align the index lines (1) with the head surface (2) (350/400)

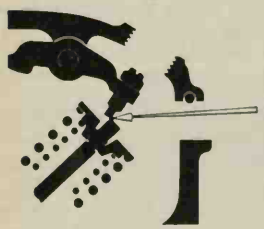
b. 500/550/650: Turn the camshaft until the center of the notch on the camshaft is aligned with the cylinder head surface, as shown. The notch must face the front of the engine.

Place the chain over the sprocket, and bolt the sprocket to the camshaft.

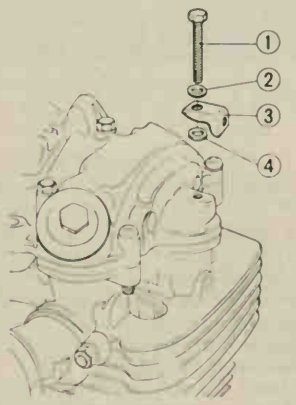
5. Install the carb assembly on the head. Install the two dowel pins and six rubber seals as shown. Install the camshaft cover gasket,



When the "T" mark (3) is lined up with the index mark, the notch (2) must face the front of the engine and align with the cylinder head surface (500/550/650)

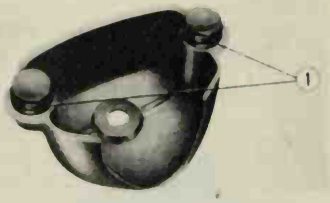


Dowel pins (1) and sealing rubbers (2) installed



refit the cover; do not forget to refit the copper washers, and torque the bolts to 5.1–8.0 ft lbs (350/400) or 6.0–8.5 ft lbs (500/550). Insert a finger into the cam cover to check the contact of each valve adjuster screw on the valve stem end. See illustration.

Head cover bolt tightening sequence (350/400)



The valve tappet adjusting screw is not properly contacting the valve

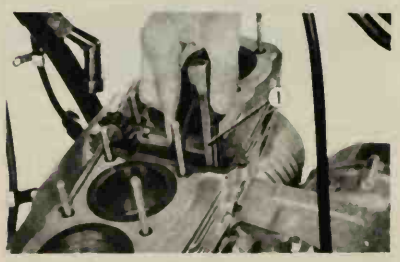
The 6 mm screw (1) secures the copper washer (2), set plate (3), and the aluminum washer (4)

6. Install the small cam cover side setplate with the chrome washer on top and the aluminum washer on the bottom. Install O-rings on the dowel pins of the left and right-side covers and mount them on the head. Install the breather cover.

NOTE: *Spark plug wire clips should face forward on both sides.*

O-ring location

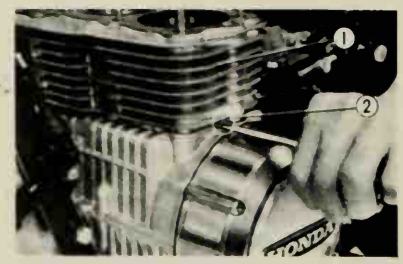
7. Reverse the disassembly procedure for the remaining components.



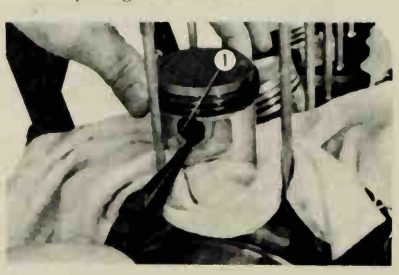
Cylinder and Piston Removal

ALL MODELS

1. Remove the cylinder head.
2. On the 350/400, remove the cam chain tensioner guide. Back off the chain tensioner locknut. Unbolt the tensioner holder and remove the cam chain tensioner.
3. On 500/550 models, raise the cam chain guide slightly, and turn it 90° and lift it out. Back off the cam chain tensioner locknut, raise the cylinder barrels about 1 in. and lift out the chain tensioner assembly.
4. On the 650, remove the cam chain tensioner locknut. Remove the tensioner and chain guide.



Lift up the chain guide and turn it 90° to remove it

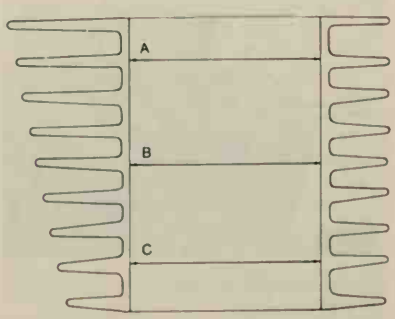


Removing the cam chain tensioner

5. Carefully raise the cylinder assembly. If it is stuck, tap lightly on the sides with a plastic mallet to break it loose. If a pry groove is fitted, use a screwdriver to break the cylinders loose, as illustrated. When the cylinder is lifted away, be careful that the pistons do not fall against the case as they come out of their bores.
6. Remove the wrist pin circlips from the pistons.

Carefully pry at the groove (2) to remove the cylinder (1)

CAUTION: *Do not allow the circlips to fall into the crankcase. To avoid having to split the cases to retrieve a clip, cover the crankcase openings with a cloth.*



Removing the piston wrist pin circlip (1)

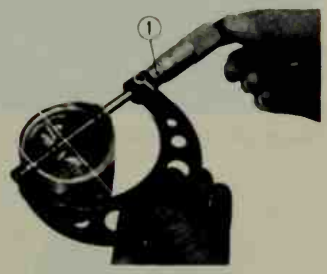
7. Grasp the piston with one hand and push out the wrist pin with a suitable drift. If the piston will not come out, the piston crown may be heated, evenly and gently, with a propane torch. If the pin still resists, it is advisable to use the shop wrist pin removal tool. This consists of a steel band or bands which fit around the piston while the attached screw device is used to push out the pin.

CAUTION: *Never strike the wrist pin or attempt to use brute force to drive it out. The connecting rod may be bent in the attempt.*

Inspection

1. Make a visual inspection of the cylinder bore, noting any imperfections. The cylinder walls should be uniformly smooth.
2. With an inside micrometer, measure the diameter of each bore at the top, middle, and bottom. Make measurements in two directions, 90° apart, both parallel and perpendicular to the piston wrist pins. If any measurement exceeds the serviceable limit given in the specifications charts at the end of this chapter, or if the difference between the high and low measurement in any given direction is greater than 0.05 mm (0.002 in.), the cylinders should be bored out to the next oversize.

Measure cylinder diameter in two directions at each of the three points shown



Maximum allowable difference between the cylinders is 0.1 mm (0.004 in.).

3. Make a visual inspection of the pistons. Scoring, scuffing, or seizure marks on the piston skirts may be removed with a fine grade of emery or crocus cloth if they are not too severe. Sanding should be done in a cross-hatch pattern. If the damage is severe (more than about ½ in. wide), the pistons should be replaced.

4. The rings must be free to move in the piston grooves. If they cannot, either they are carbon clogged (which necessitates replacing the rings and cleaning out the grooves), or metal has been pushed into the grooves by a piston seizure. In this event, pistons and rings must be replaced. Carbon-clogged rings are almost always broken when an attempt is made to remove or free them, so be prepared to buy a new set.

5. Measure the diameter of the pistons at the bottom of the skirt perpendicular to the wrist pin. If any measures less than the serviceable limit given in the charts at the ends of this section, the pistons should be replaced. If this has occurred, the cylinders are probably worn as well, and the solution is to have them bored out to the next oversize.

NOTE: *New pistons come with the wrist pin and rings. If oversized pistons are needed due to a worn bore or worn or damaged piston, obtain the pistons first, then have your dealer or a machine shop bore the cylinders to the proper size. This is obtained by measuring the diameter of the new pistons and boring the cylinders to that size plug the piston-to-cylinder clearance of 0.025–0.050 mm (0.001–0.002 in.).*

Measuring the piston diameter with a micrometer

There are four piston oversizes available in increments of 0.25 mm. The size is stamped on the piston crown.

6. If an inside micrometer is available, measure the inside diameter of the wrist pin holes and compare the reading with the specification given in the charts at the end of this chapter. The wrist pins should be a light push fit into the holes. If they are too loose, the pistons should be replaced.

7. Check the condition of the wrist pins. Measure the diameter of the pins at three places along their length and compare the diameter to the service specification. Replace the pins if the diameter is less than the serviceable limit, or if the pins are discolored from overheating.

8. The wrist pins ride directly on the connecting rod small ends. Measure the inside diameter of the small ends and compare the reading with the specifications given. If larger than the serviceable limit, the rod must be replaced.

9. Be sure that all oil passages in the cylinder are clear. Check the condition of the cam chain tensioner guides and replace them if damaged.

10. Replace the cylinder base O-rings. Check that any O-rings and the important dowel pins fitted to the cylinders are in their proper locations before installation.

PISTON RINGS

Two checks to be made on the piston rings are side clearance and end-gap. These checks should be made on both new and used rings.

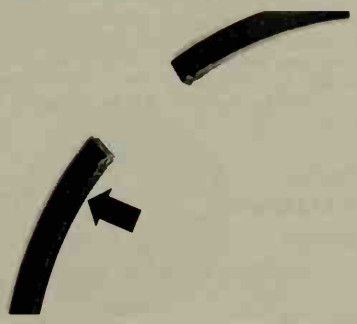
1. Piston ring side clearance for compression rings and one-piece oil rings is checked with the rings installed on the piston. Insert a feeler gauge blade between the ring and the ring groove and check that the clearance is within the specification given for your machine. If the clearance is too large, the rings or grooves are worn. If too small, metal may have been pushed into the grooves due to a piston seizure. Check that the grooves are not just carboned up. If new rings do not bring the clearance to the proper value, the pistons must be replaced.

2. To remove the rings from the piston, use a ring spreader. Decarbonize the ring grooves.

3. To check the ring end-gap, ensure first that the cylinder bore is not excessively worn. Place each ring, in turn, into the bottom of its cylinder and push it in an inch or more using the piston skirt to align the ring in the bore. Measure the end-gap with a feeler gauge. If the end-gap is larger than the service limit, the rings must be replaced. If the measured end-gap of new rings is too large, the cylinder is worn and should be bored to the next oversize.

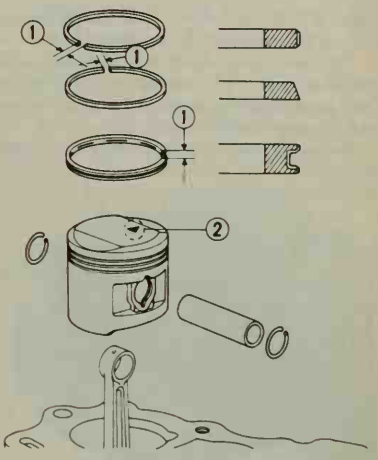
If new rings are fitted and the end-gap is too small, the ring ends must be filed. Hold the ring steady, closing the ends over a thin, fine file. Do not squeeze the ring, as this is the easiest way to break it. A few strokes of the file will increase the end-gap.

CAUTION: *Do not make more than a few strokes before checking the end-gap again. It is easy to remove too much metal.*



Do not allow the file to slip out of the ring, as this risks breaking it.

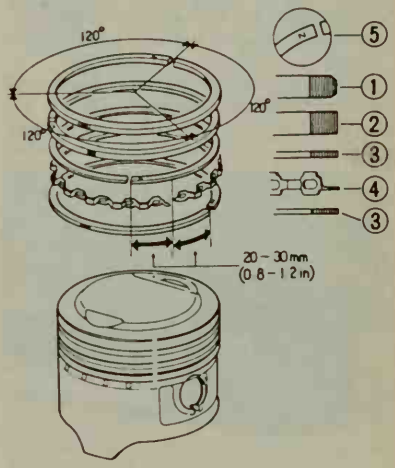
4. Roll each ring around its own groove and ensure that this can be done easily. If a ring sticks or binds in the groove, the pistons must be replaced.



Cylinder and Piston Installation

1. When installing piston rings, note that all rings are installed with the manufacturer's mark (the small letter near the end-gap) facing *up*.

NOTE: *The compression rings are not interchangeable. Refer to the illustrations showing the ring profiles.*



Install rings so that the manufacturer's mark faces up (arrow)

Make sure that the ring gaps (1) are staggered and the mark (2) is facing the exhaust side

2. To install the three-piece oil ring, install one rail on the piston below the oil ring groove, fit the expander, then move the rail into place. Install the top rail.

Installation of piston rings

3. Use a ring expander to install the rings to reduce the chance of breaking them.

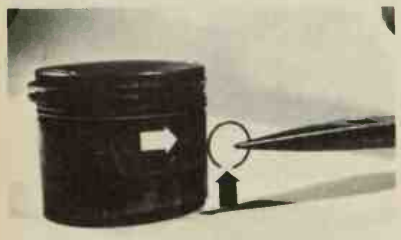
4. Ring end-gaps must be staggered around the piston so that they do not overlap. If a one-piece oil ring is used, space the end-gaps about 120° apart, but do not position any of

Ring end-gap positions (three-piece oil ring)

them at the very front or very rear of the piston, or directly over the wrist pin hole.

The same thing holds true of models with the three-piece oil ring, except that the rail end-gaps should be positioned to either side of the expander as illustrated.

5. Install the pistons on their connecting

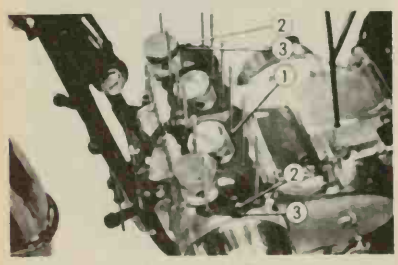


Install the pistons on the rods so that the arrows face the front of the engine

rods so that the arrow marks on the crown point towards the front (exhaust side) of the engine. Pistons marked with "IN" should have this mark positioned on the intake side.

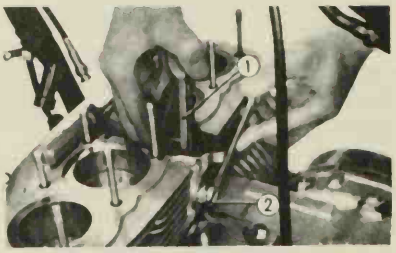
NOTE: *Be sure to use new wrist pin circlips.*

6. Slip the wrist pins into place, heating the piston crown as on removal if necessary. Install the wrist pin circlips with a needle-nosed pliers. Be sure each circlips is firmly seated in its groove and arranged so that the circlip end-gap and the cut-out in the piston do *not* align.



Install the wrist pin circlips so the end-gap and cut-out (arrows) do not align

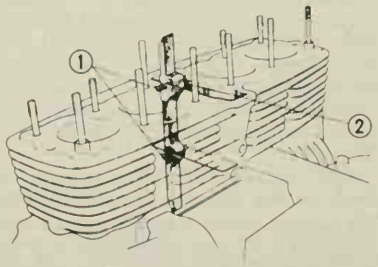
7. Lubricate the rings and piston skirts with clean motor oil.



8. Install the cylinder base gasket and the two dowel pins (oriface valve) and O-rings on the crankcase.

NOTE: *Blow compressed air through the dowel pin holes before installation to make sure they are not clogged.*

9. Rotate the engine until No. 2 and 3 pistons are at Top Dead Center and place a piston base (Honda part number 07033-33301 for the 350/400, or, for the others, 07033-



Gasket (1) dowel pins (2) and O-ring (3) placement is critical

Installing the tensioner (1) and locknut (2)

55102) under the pistons to hold them in position. (A block of wood cut to suitable size works just as well). Compress the rings on No. 2 and 3 pistons and slide the cylinder down over them. Rotate the engine until No. 1 and 4 pistons contact the base of the cylinder (taking care not to pull No. 2 and 3 pistons out of their bores), compress the rings, and slide the cylinder against the crankcase, raise the cam chain through the center of the cylinder and put a screwdriver through the center of it to keep it from dropping down. Also, with the cylinder about one in. from the crankcase, install the cam chain tensioner in the cylinder. Hold the tensioner down by hand and install the O-ring and washer, and tighten the lock-

Chain guide pins (1) and "up" mark (2)

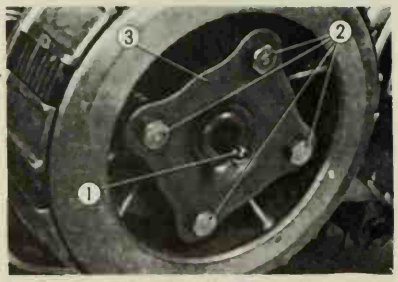
nut. Install the cam chain guide into the cylinder as illustrated so the "UP" mark is correctly positioned (500/550).

NOTE *If the cylinder studs are to be replaced, a special stud wrench (Honda part number 07779-99902) should be used because the studs are secured with thread-locking compound. When installing new studs, thoroughly clean the stud holes, apply thread-locking compound, and torque the studs to 15–16 ft lbs.*

CRANKCASE COVER COMPONENTS

The following sections deal with the removal, inspection, and installation of those components found beneath the left and right crankcase covers. These include the clutch, breaker points, and alternator. These components can be serviced with the engine in the frame.

Clutch



DISASSEMBLY

350/550

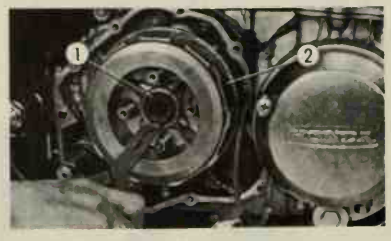
1. Drain the oil from the sump.

2. Remove the kick-start lever and the right-side footrest.

3. Take out the screws and pull off the right-side rear crankcase (clutch) cover.

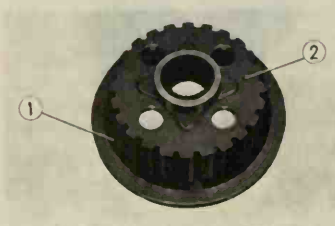
Clutch pushrod (1), bolts (2) and pushrod plate (3)

4. Remove the clutch lifter rod from the center of the mainshaft.



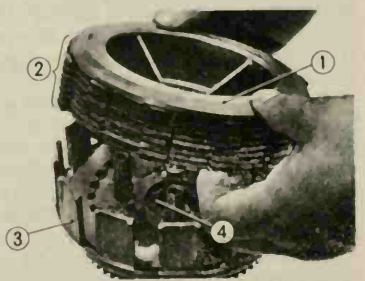
5. Remove the four bolts from the lifter plate evenly and remove the lifter plate, and clutch springs.

6. Remove the 25 mm snap-ring from the mainshaft in the center of the clutch hub, and pull the clutch assembly off the mainshaft.



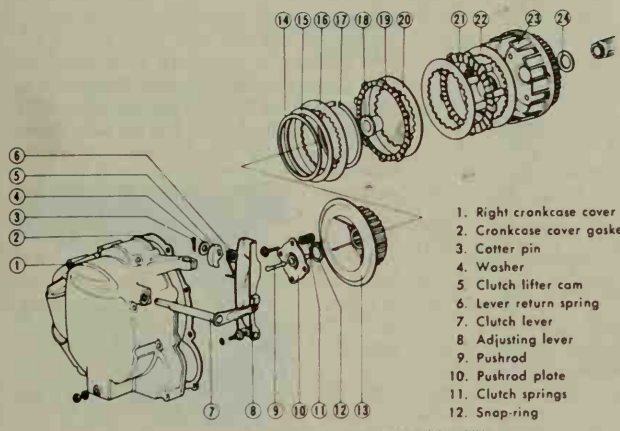
7. Remove the clutch hub, discs, and plates from the clutch housing. On 350 models the hub can be further disassembled by removing the 92 mm set ring, special plate, clutch disc spring, and disc spring seat.

If it is desired to remove the release or adjuster mechanisms:

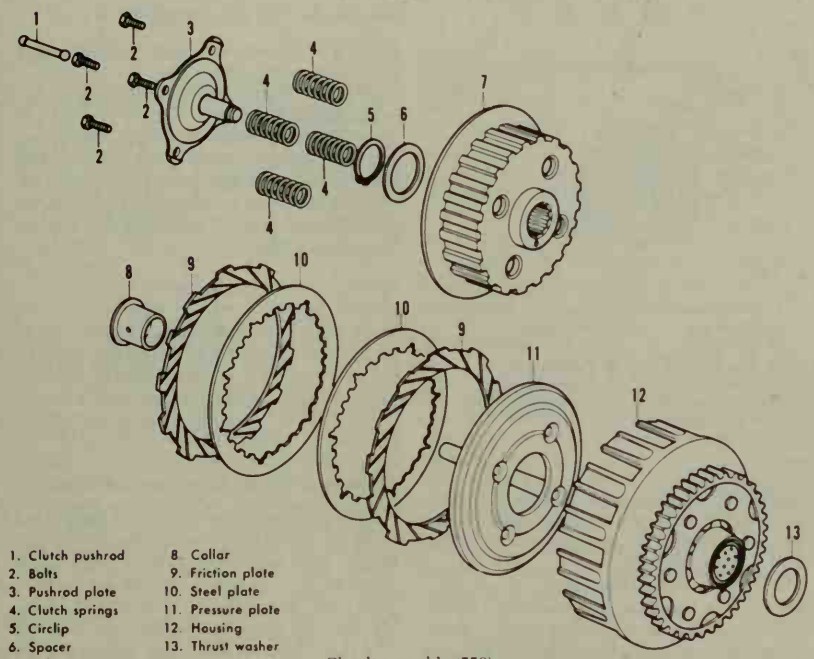


8. Remove the cotter pin from the clutch lever inside the right crankcase cover. Withdraw the clutch lever from the case.

Removing the clutch circlip



Remove the set ring (1) to further disassemble the clutch hub (2)



Removing the clutch hub (1) and plates (2) from the housing (3) and pressure plate (4)

9. Remove the locknut and washer from the clutch adjuster, and withdraw the clutch adjusting lever from the case.

1. Right crankcase cover
2. Crankcase cover gasket
3. Cotter pin
4. Washer
5. Clutch lifter cam
6. Lever return spring
7. Clutch lever
8. Adjusting lever
9. Pushrod
10. Pushrod plate
11. Clutch springs
12. Snap-ring
13. Clutch hub center
14. Disc spring seat
15. Disc spring
16. Steel plate
17. Set ring, 92 mm
18. Collar
19. Friction plate
20. Steel plate
21. Friction plate
22. Pressure plate
23. Housing
24. Thrust washer

Clutch assembly (350)

1. Clutch pushrod
2. Bolts
3. Pushrod plate
4. Clutch springs
5. Circlip
6. Spacer
7. Hub
8. Collar
9. Friction plate
10. Steel plate
11. Pressure plate
12. Housing
13. Thrust washer

Clutch assembly (550)

400

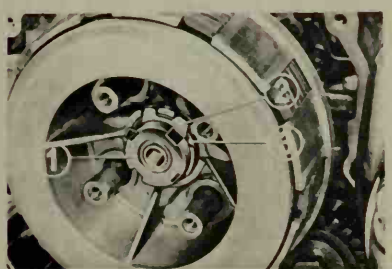
1. Drain the oil from the sump.

2. Remove the kick-start lever, and the right footrest. Remove the rear brake adjusting nut from the brake rod.

3. Remove the two screws securing the release mechanism cover plate to the right crankcase cover and remove the cover plate.

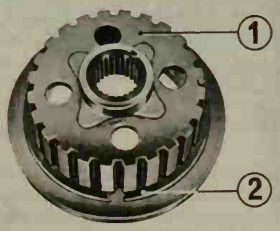
4. Disconnect the clutch cable from the release lever. If necessary, screw the cable adjuster into the crankcase cover to allow more free-play in the cable.

5. Remove the right crankcase cover.



6. Remove the four bolts from the lifter plate evenly and remove the lifter plate, and clutch springs.

7. Remove the special locknut from the center of the clutch hub using the special tool (Tool number 07916-6390000) after bending back the tabs on the lockwasher. Remove the clutch assembly.



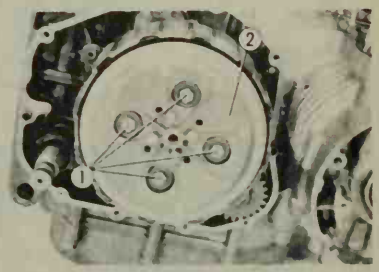
8. Remove the hub and plates from the clutch housing. Lift the steel plates and the friction discs from the clutch hub. The hub can be further disassembled by removing the 92 mm set ring, special plate, clutch disc spring, and the disc spring seat.

If it is desired to remove the release or adjuster mechanism from the crankcase cover:

9. Remove the locknut from the clutch adjusting screw, and remove the release lever and lever spring. Remove the clutch cam plate, ball retainer, clutch lifter, and adjusting screw from the inside of the cover.

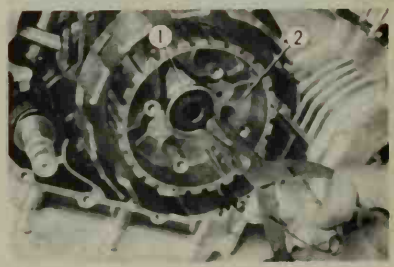
Locknut (1), tab washer (2) and lockwasher (3)

Clutch hub (1) and set ring (2)



500

1. Drain the engine oil.

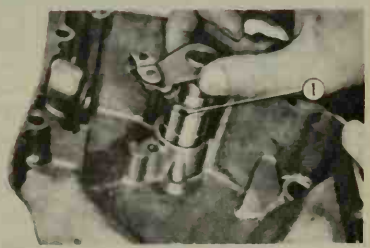


2. Remove the kick-start lever.

3. Take out the screws and pull off the right-side rear crankcase (clutch) cover.

4. Unscrew the four pressure-plate mounting bolts and remove the plate and four springs. Remove the release piston.

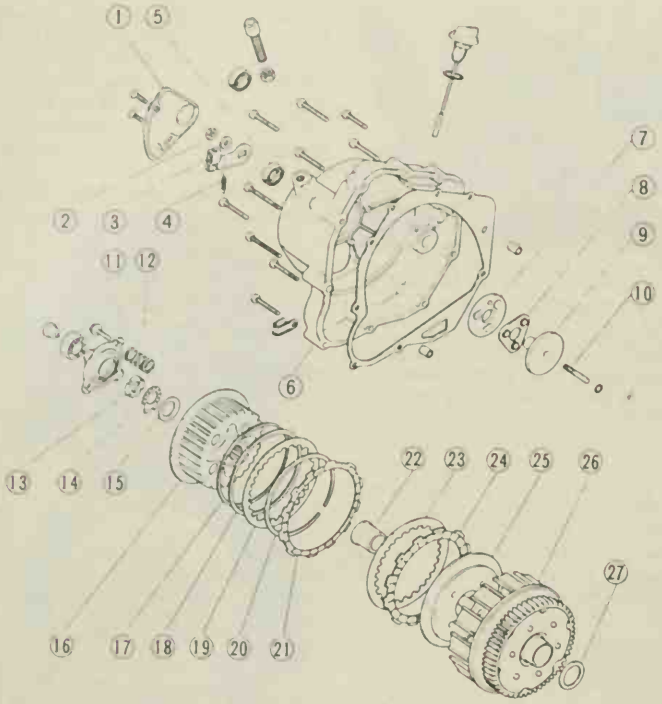
Remove the pressure plate mounting bolts (1)



Removing the snap-ring (1) which secures the clutch hub (2)

5. Remove the large circlip and shims (if any). Pull the clutch hub assembly off the mainshaft.

6. Remove the clutch center section, discs, and plates from the clutch housing.



If it is desired to remove the release or adjuster mechanisms:

7. Remove the left-side, rear crankcase cover and disconnect the clutch cable from the release lever.

Removing the release mechanism (1)

8. Unscrew the clutch adjuster lockbolt and remove the adjuster from the left crankcase cover. Pull the release rod out of the crankcase.

Clutch assembly (400)

1. Clutch cover
2. Locknut
3. Release lever
4. Spring
5. Oil seal
6. Right crankcase cover
7. Cam plate
8. Ball retainer
9. Lifter
10. Adjusting screw
11. Lifter Plate
12. Clutch spring
13. Locknut
14. Tab washer
15. Lockwasher
16. Clutch hub
17. Spring seat
18. Disc spring
19. Special plate
20. 92 mm set ring
21. Friction disc
22. Collar
23. Steel plate
24. Friction disc
25. Pressure plate
26. Clutch housing
27. Thrust washer

650

1. Drain the engine oil.

2. Remove the right side rider's footpeg. Disconnect the clutch cable at the clutch cover.

3. Remove the clutch cover.

4. If dissassembly of the clutch lifter is desired, remove the adjusting screw, adjusting arm, and lifter shaft.

5. Remove the lifter guide, bearing, and bearing retainer from the clutch.

6. Remove the clutch spring bolts, loosening them gradually. Remove the lifter plate and springs.

7. Put the transmission in gear and apply the rear brake so that the engine will not turn over. Use the special clutch hub nut socket to remove the hub nut.

8. Remove the clutch assembly from its shaft.

INSPECTION

1. Check the condition of the kick-start-shaft oil seal. If it leaks, or if the lips show signs of damage, pry the old seal out with a small screwdriver. Press the new seal straight into the cover. Apply some oil or grease to the seal lips before installation.

2. Check the condition of the clutch cover mating surface. Remove any burrs or imperfections with an oilstone.

3. Measure the thickness of the friction plates with a vernier caliper and replace them as a set if any is less than the serviceable limit which is 2.3 mm (0.091 in.) for the 350/400, and 550, and 3.0 mm (0.11 in.) for the 500. On the 650, the outermost friction plate has a replacement limit of 2.4 mm (0.09 in.) while the others should be replaced as a set if less than 3.2 mm (0.13 in).

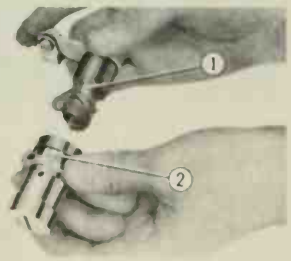
4. Place the steel clutch plates on a flat surface, such as a piece of glass, and check for excessive warpage by attempting to slip a feeler gauge blade between the plate and the surface. Replace the steel and friction plates as a set if warpage exceeds 0.2 mm (0.008 in.) for the 350/400 or 0.3 mm (0.011 in.) for the 500/550/650.

5. Measure the free length of each clutch spring and replace them as a set if any is less than the serviceable limit which is 34.0 mm (1.34 in.) for the 350, 29.8 mm (1.71 in.) for the 400, 30.5 mm (1.20 in.) for the 500, and 35.4 mm (1.39 in.) for the 550 and 650.

Be sure that the springs are tightened evenly on assembly.

6. Check the friction plate tabs for wear or damage. Check the clutch housing for indented wear caused by the tabs. Remove any burrs with a file or oilstone.

7. Check the corresponding splines of the clutch hub and steel plates for indented wear.



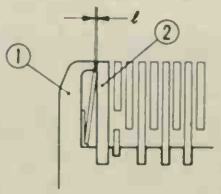
8. Check the condition of the lifter plate bearing, if fitted. Rotation must be smooth, noiseless, and effortless. Replace the bearing if rotation is rough, the races loose, or rotation noisy.

9. On the 650, measure the outside diameter of the clutch bushing and the inside diameter of the clutch hub. The former should be at least 29.94 mm (1.18 in.), the latter no more than 30.05 mm (1.18 in.).

ASSEMBLY

350/550

1. Install the clutch adjusting lever into the crankcase cover. Install a washer and locknut onto the adjusting screw. Slip the clutch lever into the case while installing the lever spring.



Installing the lifter (1) to the adjuster (2)

Install a 10 mm washer on the end of the lever and secure with a cotter pin.

2. Install the 25 mm collar into the center of the clutch housing.

3. 350 only: Install the clutch disc spring seat, disc spring, special clutch plate, and 92 mm set ring onto the clutch hub. Check the clutch hub-to-special plate clearance. If the clearance exceeds 0.5 mm (0.02 in.), replace the special plate.

Check the clutch hub (1) to plate (2) clearance (b)

4. Install the friction discs and steel plates on to the clutch hub. On 350 models the first friction plate to be installed has a larger inside diameter than the others. Install the pressure plate over the last friction plate. On 550 models, be sure the friction plates are installed with the oil grooves positioned as shown in the illustration.

5. Install the hub assembly into the clutch housing. Install the 25 mm thrust washer on the mainshaft, then install the clutch assembly on the mainshaft, and secure with a 25 mm snap-ring.

6. 550 only: Check end-play of the clutch assembly with a dial indicator, and if end-play exceeds 0.1 mm (0.004 in.), a shim should be installed behind the circlip. Shims are available in thicknesses of 0.1, 0.3, and 0.5 mm.

7. Install the clutch springs, lifter plate, and lifter rod.

8. Install the clutch cover, and adjust the clutch.

400

1. Install the clutch cam plate, ball retainer, clutch lifter, and adjusting screw into the inside of the crankcase cover. Install the release lever, lever spring, and locknut on the adjusting screw.

2. Install the disc spring seat, disc spring, and the special clutch plate on the hub and secure with a 92 mm set ring.

Check the clutch hub-to-special plate clearance. If the clearance exceeds 0.5 mm (0.02 in.) replace the special plate.

3. Install the remaining plates and friction discs on the hub. Note that the first friction disc installed on the hub has a larger inside diameter than the other friction discs.

4. When all of the plates and discs are installed, fit the pressure plate over the top friction disc.

5. Fit the center collar to the clutch housing. Install the thrust washer on the mainshaft, and install the clutch housing.

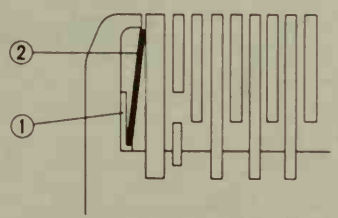
6. Install the hub assembly into the clutch housing. Secure the hub on the shaft with a lockwasher, tab washer, and special locknut. The large tab on the tab washer should fit over the lug on the hub. Bend at least one of the tabs of the tab washer into a slot in the locknut.

7. Install the clutch springs, and lifter plate. Install the four clutch bolts.

8. The remainder of assembly is the reverse of disassembly.

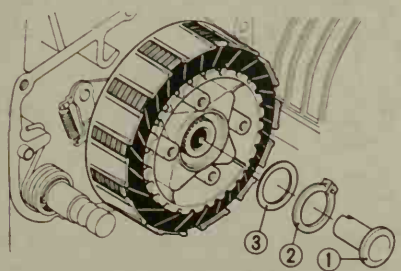
500

1. Install the release rod into the crankcase so that the round end is toward the right-side.



2. Apply grease to the clutch release, assemble it into the adjuster, and install it in the left crankcase cover. Tighten the lockbolt and connect the clutch cable to the release lever.

3. Install the steel ball into the clutch release and mount the left crankcase cover on the engine.



4. Coat the friction discs with fresh engine oil and assemble the discs and plates onto the center section. Install the center section in the clutch housing. Don't forget the thrust washer. Be sure the friction discs are installed with the oil grooves positioned as shown in the illustration.

NOTE: *Beginning with engine number CB 550E-1018728, modified clutch discs and plates have been used. Earlier engines suffering from clutch slip may be modified with these parts, as they are interchangeable.*

5. Install the clutch assembly on the mainshaft and lock it in place with the circlip. Check end-play of the clutch assembly with a dial indicator, and if end-play exceeds 0.004 in. (0.1 mm), a shim should be installed behind the circlip. Shims are available in thicknesses of 0.1, 0.3, and 0.5 mm.

Make sure that the disc spring seat (1) and disc spring (2) are properly seated

End-play can be taken up with a shim (3) behind the circlip (2); (1) is the clutch collar

6. Slip the release piston into the mainshaft and install the pressure plate, with springs on the clutch housing.

7. Install the crankcase (clutch) cover using a new gasket.

8. Refill the engine with oil, and adjust the clutch.

650

1. Assembly is the reverse of disassembly. Be sure that the thrust washer is fitted to the shaft behind the clutch.

2. Be sure that the hub nut washer is installed with the "Outside" facing outwards.

3. Tighten the hub nut to 34–38 ft. lbs.

4. Install the lifter plate with the cupped side facing outwards.

5. Pre-lube the clutch assembly.

Ignition Timing Assembly

REMOVAL

1. Remove the breaker points cover. Disconnect the two leads behind the engine.

2. Remove the small bolt which secures the special nut used to turn the engine over.

3. Remove the three screws which secure the breaker plate and remove it.

4. Pull off the timing advance mechanism as a unit, taking care not to take apart the mechanism and breaker cam.

Inspection

1. For inspection of points, condensers, etc., refer to "General Information."

2. The timing advance mechanism movement must be free. When the breaker cam is turned so that the weights move out to the fully extended position, releasing the cam should result in its returning to the original location. If it will not, try penetrating oil or the like to ease movement. Check for weak springs. Replace the unit if proper action cannot be obtained.

INSTALLATION

Installation is the reverse of removal. Note that the timing advance mechanism is located with a pin on the crankshaft.

Alternator

REMOVAL

1. Remove the alternator cover.

2. Remove the alternator rotor mounting bolt.

Removing the rotor (1) with the special puller (2) (350/400)

3. The rotor is a push-fit onto the tapered crankshaft. Remove the rotor with the special tool (number 07011-33301 for the 350/400 or 07011-21601 for the 500/550 or 07733-0020001 for the 650).

INSPECTION

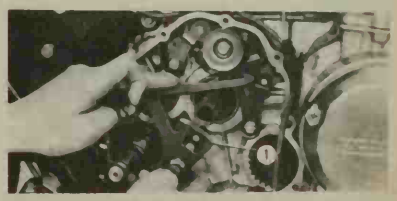
Refer to "Electrical System," for alternator tests.

INSTALLATION

Tighten the rotor bolt to 22–29 ft. lbs. for the 350/400 or 29–30 ft. lbs. for the 500/550 and 36–43 ft. lbs. for the 650.

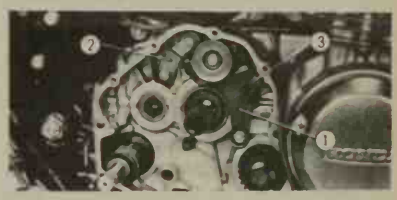
LOWER END

Disassembly



350/400

1. Drain the oil from the sump and oil filter, then remove the engine from the frame as directed in the "Engine Removal and Installation" section.



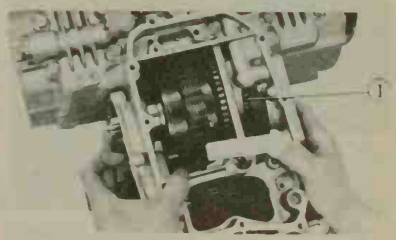
2. Disassemble the top end as described in the "Top End" section.

3. Remove the alternator rotor using a suitable rotor puller (Honda part number 07011-33301).

4. Remove the right crankcase cover, clutch and gearshift spindle, then disassemble

Removing the shift spindle (350/400)

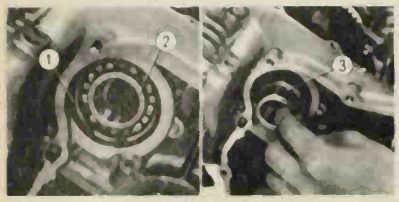
Remove the positive stopper (1), shift drum stopper (2), and neutral stopper arm (3) (350/400)



the positive stopper, gearshift drum stopper, and the neutral stopper arm.

5. Remove the contact breaker and automatic advance mechanism.

6. Invert the engine and remove the oil pan and oil pump assembly.



Remove the 12 mm bolt (1) in order to remove the lockwasher (2) and secondary drive gear (3) (350/400)

Removing the primary shaft (1) (350/400)

7. Remove the 12 mm bolt from the end of the primary shaft, slide the secondary drive gear off the primary shaft, then slip the primary shaft out to the right.

8. Remove the internal circlip (52 mm),

Remove the internal circlip (1) and bearing (2), then remove the collar (3) (350/400)

the ball bearing, and the 25 mm collar as illustrated.

9. Evenly loosen the bolts from the lower crankcase working in a criss-cross pattern from the inside out, then gently tap the cases with a soft mallet to separate them.

10. Remove the transmission and shifter components if necessary. The gear assemblies should be removed simultaneously.

500/550

1. Remove the engine from the frame and remove the cylinder head, cylinder barrel, and pistons as described in the preceding section on top end overhaul.

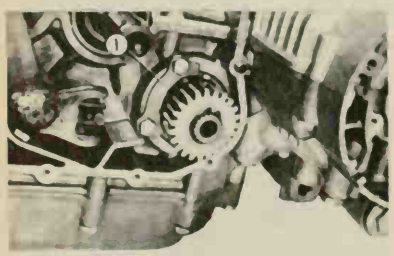
2. Take off the alternator cover and remove the rotor using, if possible, a rotor puller (Honda part number 07011-21601).

3. Remove the ignition points cover and unscrew the 6 mm bolt at the end of the breaker cam. Remove the hexagonal washer. Take out the three phillips head screws and remove the complete breaker plate assembly.

4. Remove the clutch unit as described under "Clutch."

5. Remove the shift lever. Withdraw the shift linkage from the right-side of the engine while holding the shift arm down.

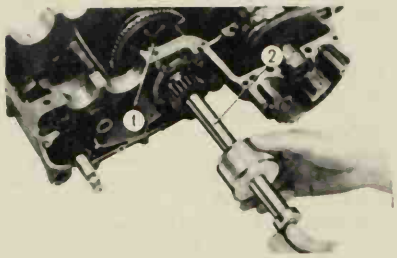
6. Take off the starter cover and remove the starter motor.



7. Place the engine upside down, preferably on a large piece of cardboard. Unscrew the ten bolts, and remove the oil pan and oil pump pick-up.

8. Unscrew the ten 8 mm lower crankcase bolts, gradually, in reverse order of the tightening sequence. Remove the thirteen 6 mm bolts from the lower crankcase.

9. Turn the engine over again so that it is resting on the lower crankcase in its normal position and remove the three 8 mm and three 6 mm bolts.



10. Separate the crankcase halves by tapping with a rubber mallet and lifting the upper crankcase away. Lift the transmission mainshaft and countershaft assemblies out of the case. Do not lose the bearing set rings.

NOTE: *Be very careful not to mar the mating surfaces of the crankcase halves during handling or when removing old gasket cement.*

Bearing set plate location (1) (500 and 550)

11. Unscrew the two bolts and remove the transmission primary shaft bearing set plate. Remove the circlip and pull out the primary shaft using tool number 07009-32301 or a suitable gear puller. Lift out the starter clutch and primary sprocket assembly.

Removing the primary shaft (1) with a puller (2) (500 and 550)

12. Lift out the crankshaft. Unbolt the connecting rod bearings caps, remove the rods, and slip the cam and primary chains off the crankshaft. Mark or tag the rods so that they may be installed in their original positions.

650

1. Remove the engine from the frame. Remove the oil filter, oil pan, and strainer.

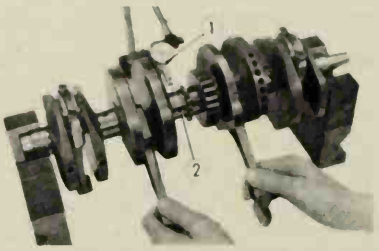
2. Remove the cylinder head, cylinders, and pistons.

3. Remove the clutch. Remove the gearshift linkage.

4. Remove the alternator rotor, pulser generator, spark advance mechanism, and starter motor.

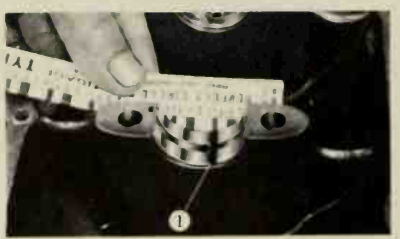
5. Remove the upper crankcase bolts. Turn the engine over and remove the lower crankcase bolts. Bolts should be loosened gradually and in a cross pattern to eliminate the chances of warpage.

6. Remove the primary shaft circlip. Use a gear puller to remove the primary drive gear. Remove the bearing stopper plate.



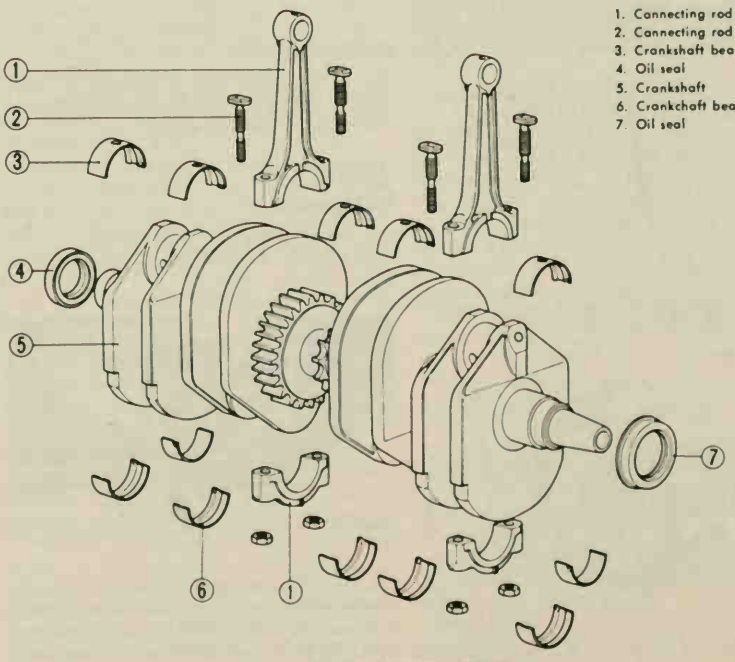
7. Disconnect the primary chain tensioner spring.

8. Remove the primary shaft. This must be done with a slide-hammer or similar tool.



9. Separate the crankcase halves. The crankshaft and transmission will remain in the upper case half.

Inspection



Check the crankshaft run-out by placing the ends of the crankshaft in V-blocks and rotating the shaft while taking a reading with a dial indicator at the center journal. Replace the crankshaft if run-out exceeds 0.05 mm (0.0019 in.). (Run-out equals one-half the dial indicator reading.)

Checking crankshaft (2) run-out with a dial indicator (1)

Using plastigauge (1) to obtain the bearing clearance

1. Connecting rod and cap
2. Connecting rod bolt
3. Crankshaft bearing half
4. Oil seal
5. Crankshaft
6. Crankchaft bearing half
7. Oil seal

Crankshaft assembly (350/400)

MAIN BEARINGS

Inspect the bearing journals for scoring and damage. Measure the journal diameter in several places to check for ovality and taper. Maximum acceptable variation of journal diameter is 0.05 mm (0.0019 in.).

Journal wear can be checked using a material such as plastigauge. Cut strips of plastigauge to fit across each bearing, install the crankshaft and lower crankcase, and torque

Checking bearing seat diameter with a dial gauge (1)

the ten 8 mm lower crankcase bolts in the correct sequence to 15 ft lbs. Do not turn the crankshaft and measure the plastigauge with the scale provided. If clearance exceeds 0.08 mm (0.0032 in.), the bearings should be replaced. Bearings that are damaged in any way should not be reused.

MAIN BEARING SELECTION

If the main bearings are to be replaced, two measurements must be made: inside diameter of the bearing seats and crankshaft journal diameter. To check bearing seat diameter, assemble the upper and lower crankcases with the ten bolts, as described above. Measure the seats with an inside dial indicator in the vertical direction and select from the following code letters according to measurements obtained for each bearing seat.

Code Letter Size Chart (Bearing Seat Diameter)

500/550/650

Seat Diameter	Code
1.4173–1.4176 in./ 36.000–36.008 mm	A
1.4176–1.4179 in./ 36.008–36.016 mm	B
1.4179–1.4182 in./ 36.016–36.024 mm	C

350/400

Seat Diameter	Code
1.3780–1.3783 in./ 35.000–35.008 mm	A
1.3783–1.3786 in. 35.008–35.016 mm	B
1.3786–1.3789 in./ 35.016–35.024 mm	C

Next, measure the crankshaft bearing journal diameters with a micrometer and select one of the following two code numbers for each journal.

Code Number Size Chart (Journal Diameter)

500/550/650

Journal Diameter	Code
1.2987–1.2992 in./ 32.99–33.00 mm	1
1.2983–1.2987 in./ 32.98–32.99 mm	2

350/400

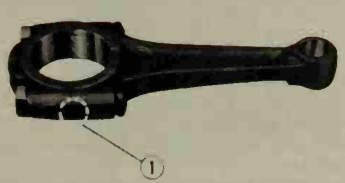
Journal Diameter	Code
1.2586–1.2590 in./ 31.97–31.98 mm	1
1.2590–1.2594 in./ 31.98–31.99 mm	2
1.2594–1.2598 in./ 31.99–32.00 mm	3

Use the codes obtained to pick out the proper bearings from the bearing selection chart.

Bearing Selection Chart

500/550/650

		Code Number 1	Code Number 2
Code Letters	A	D yellow	C green
	B	C green	B brown
	C	B brown	A black



350/400

		Code Number 1	Code Number 2	Code Number 3
Code Letters	A	B brown	C green	D yellow
		A black	B brown	C green
	B	AA black	A brown	B brown
	C	blue	black	brown

CONNECTING RODS AND BEARINGS

ROD BEARING SELECTION

Connecting rod bearings need not be replaced unless the bearing shells show signs of wear and/or damage, or if there is excessive clearance between the bearing and crankpin. To check the clearance, cut a strip of plastigauge and place it across the bearing shell, as when checking main bearing clearance. Install the rod bearing cap and torque the nuts to 15 ft lbs. Do not turn the crankshaft or move the connecting rod. Remove the bearing cap and measure the plastigauge with the scale. Maximum acceptable clearance is 0.08 mm (0.0032 in.).

Con rod bearing code number

If the rod bearings are to be replaced, measure the diameter of the crankpin and select from the following bearing code letters.

Code Letter Size Chart (Crankpin Diameter)

500/550/650

Crankpin Diameter	Code
1.3775–1.3780 in./ 34.99–35.00 mm	A
1.3771–1.3775 in./ 34.98–34.99 mm	B

350/400

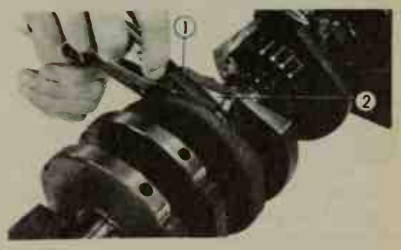
Crankpin Diameter	Code
1.2586–1.2590 in./ 31.97–31.98 mm	A
1.2590–1.2594 in./ 31.98–31.99 mm	B
1.2594–1.2598 in./ 31.99–32.00 mm	C

Now using the code letter obtained above and the code *number* stamped on the connecting rod, select the proper bearings from this chart.

Bearing Selection Chart

500/550/650

		Code Letter A	Code Letter B
Code Number	1	D yellow	C green
		C	B
	2	green	brown
		B	A
	3	brown	black



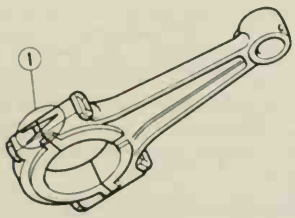
350/400

		Code Letter A	Code Letter B	Code Letter C
Code Number	1	C green	D yellow	E red
		B	C	D
	2	brown	green	yellow
		A	B	C
	3	black	brown	green

CONNECTING ROD REPLACEMENT

1. Measure the con rod side clearance. Clearance for the 350/400 must not exceed 0.15 mm (0.0059 in.); clearance for the 500/550/650 must not exceed 0.35 mm (0.0138 in.).

2. Measure the inside diameter of the con rod small ends. Bushing diameter should be no greater than 13.1 mm (0.516 in.) for the 350/400; 15.07 mm (0.593 in.) for the 500, 550, and 650.



Checking connecting rod side clearance with a feeler gauge (1)

Measuring the connecting rod small end diameter with a dial gauge (1)

3. If either of the above measurements is greater than the limits given, the rod should be replaced.

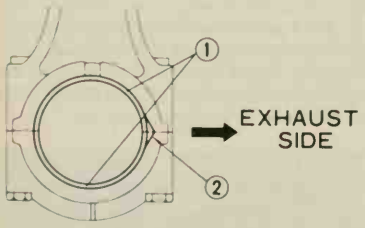
4. A replacement con rod of the same weight as the original should be selected. Rod weight can be determined by the code *letter*

Weight code letter location (1)

stamped on the big end of the rod. When replacing all four rods, ensure that the weight variation between them does not exceed five grams.

NOTE: *Rod weight includes the con rod cap and bolts, but does not include the bearing inserts.*

Rods marked "A" or "B" are replaced with rods marked "B."

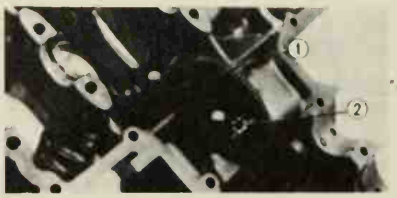


Rods marked "C," "D," or "E" are replaced with rods marked "D."

"F" and "G" rods are replaced with "F"-marked rods.

ASSEMBLY

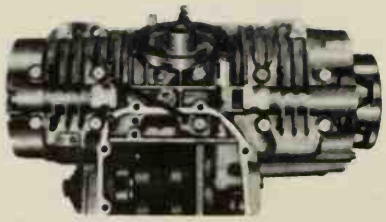
350/400



1. Assembly is basically in the reverse order of disassembly. Rods must be fitted to the crank with the tang facing the exhaust side of the engine. Make sure that all components are thoroughly clean, and coat all bearing surfaces with a suitable lubricant. New gaskets, oil seals, and O-rings should be used.

Be sure the rods are correctly installed on the crankshaft

2. When installing the cam chain tensioner push bar, do so with the mark facing upward. Depress the bar by hand and lock it in place with the adjusting bolt and locknut.



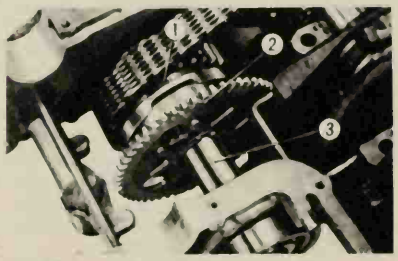
3. Install the primary chain guide with its recessed mark facing the transmission.

Install the primary chain guide (1) with the mark (2) facing up (350/400)

4. Apply a uniformly thin coat of a suitable liquid gasket compound to the crankcase mating surfaces, taking care not to foul any bearing surfaces.

5. Check that all dowel pins are properly installed before fitting the case halves together.

Crankcase bolt tightening sequence (350/400)



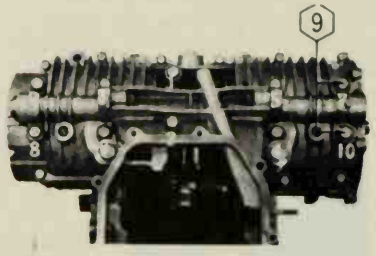
6. Secure the ten bolts on the crankcase in the order shown, torquing them to 16.6–18.1 ft lbs (2.3–2.5 kg/m).

500/550

1. Position the main bearing shells in the crankcase halves and coat them with engine oil.

2. Install the primary and cam chains on the crankshaft and intall the connecting rods, in their original positions, tightening the nuts to 15 ft lbs. Note that the rods must be installed on the crank so that the bearing insert keys face the front of the engine. Place the crankshaft assembly in the upper crankcase.

3. Install the primary chain around the starter clutch and, holding the starter gear and clutch in position, drive the primary shaft in from right to left. Be careful not to damage the needle bearings in the starter gear hub and do not forget to install the circlip. Install the mainshaft and countershaft gear assemblies, taking care to position the bearing set rings and dowel pins correctly.

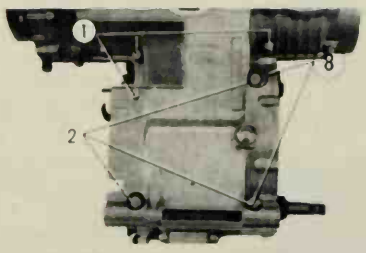


Installing the starter clutch (1) and gear (2) on the primary shaft (3) (500/550)

4. Install the bearing set plate with the two 6 mm retaining bolts.

5. Apply a *thin* coat of gasket cement to the lower crankcase mating surface, install the dowel pins (if removed), and install the upper crankcase.

6. Hold the crankcases together tightly and turn the engine upside down. Install the ten 8 mm bolts and torque them, in the sequence shown, to 17–18 ft lbs.



NOTE: *Position the two bolts with "9" stamped on the bolt head as shown in the tightening sequence.*

Crankcase bolt tightening sequence (500 and 550)

7. Install the thirteen 6 mm bolts and torque them to 8 ft lbs.

8. Turn the engine over again so it is resting on the bottom crankcase and install the three 6 mm and three 8 mm bolts. Position the two 8 mm bolts marked "8" on the bolt head as indicated in the illustration.

6 mm (1) and 8 mm (2) bolt positions (500 and 550)

9. Install the oil pump pick-up and mount the oil pan with the ten 6 mm bolts.

10. Install the starter motor.

11. Install the shift linkage, as removed, and install the shift lever.

12. Mount the clutch assembly in accordance with procedures given in the section on clutch service.

13. Place the ignition advance dowel pin in the hole in the crankshaft and mount the oil pan with the ten 6 mm screws. Install the special washer with the 6 mm bolt in the breaker cam.

14. Install the alternator rotor and tighten the bolt to 30 ft lbs. Install the alternator cover.

650

1. Prelube the con rod bearings and fit each rod onto its proper crankpin.

NOTE: *The code number on each rod must face the front of the engine.*

Tighten the rod bolts gradually and evenly to 17–20 ft. lbs.

2. Clean the crankcase mating surfaces thoroughly.

3. Apply a non-permanent liquid sealant to the mating surface of the lower crankcase.

CAUTION: *Keep the sealant clear of oil passages and bearings.*

4. Pre-lube the crank bearings.

5. Be sure that the transmission shaft bearings and oil seal are properly seated.

6. Position the primary chain and damper assembly. Assemble the crankcase halves.

7. Drive the primary shaft in with a plastic mallet.

8. Install the bearing stopper plate, pri-

mary drive gear, and circlip. Connect the tensioner spring.

9. Tighten the crankcase bolts gradually and in a cross pattern.

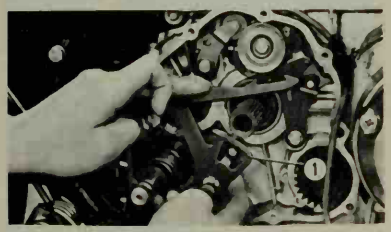
8 mm bolts: 16–19 ft. lbs.
6 mm bolts: 7–10 ft. lbs.

NOTE: *Crankshaft bolts should be lubricated with moly grease.*

TRANSMISSION

Shifter Mechanism

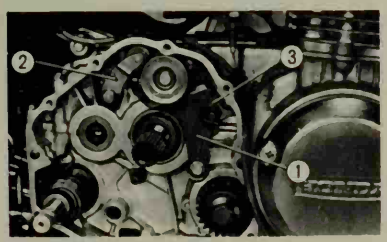
DISASSEMBLY



350/400

NOTE: *For convenience sake, Honda breaks the shifter mechanism down into two sub-groups. Group "A" components can be serviced with the engine still mounted in the frame. Group "B" components can only be serviced once the engine has been dismantled.*

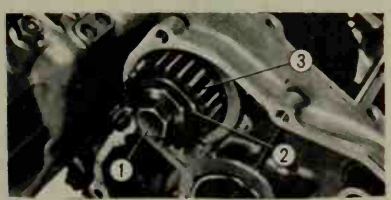
GROUP A



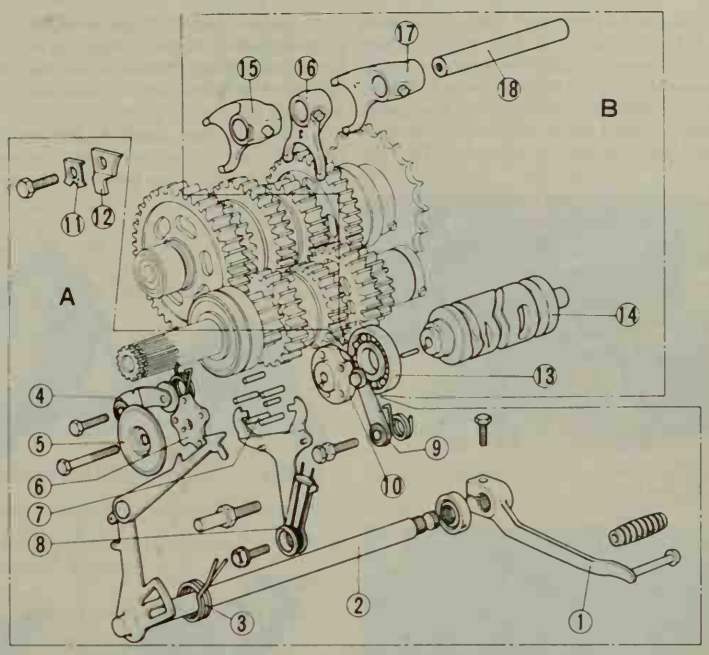
1. Run the engine until normal operating temperature is reached, then drain the sump. Place the transmission in the Neutral position.

2. Remove the right-side footrest, the kickstarter pedal, the shift lever, the right-side crankcase cover, and the gear shift spindle.

Removing the gearshift spindle



3. Remove the positive stopper, the gear shift drum stopper, and the neutral stopper arm.

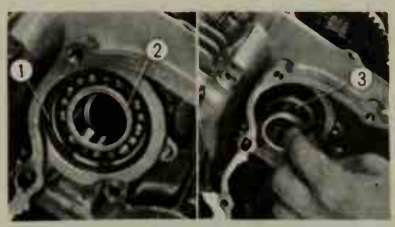


Positive stopper (1), drum stopper (2), and neutral stopper arm (3)

4. Remove the contact breaker cover, base plate assembly, and advance mechanism.

5. Remove the oil pump, then remove the secondary drive gear from the primary shaft after removing the 12 mm bolt.

Remove the 12 mm bolt (1) and lockwasher (2) to remove the secondary drive gear (3)

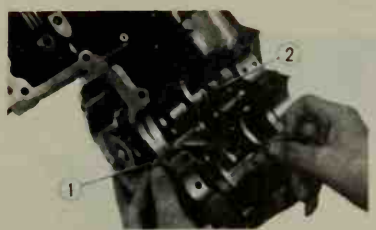


Shifter mechanism (350/400)

Group A (On-vehicle operations)	Group B (Engine removal required)
1. Gearshift pedal	10. Gearshift drum center
2. Gearshift spindle	11. Lockwasher, 8 mm
3. Return spring	12. Guide shaft set place
4. Gearshift drum stopper	13. Ball bearing
5. Gearshift side plate	14. Gearshift drum
6. Drum stopper plate	15. Gearshift fork (right)
7. Rollers (6)	16. Gearshift fork (center)
8. Positive stopper	17. Gearshift fork (left)
9. Neutral stopper arm	18. Shift fork guide shaft

GROUP B

1. Remove the engine from the frame as directed in the "Engine Removal and Installation" section, then perform all of the steps listed in the preceding section.



Remove the circlip (1) and bearing (2) to remove the collar (3)

2. Pull the primary shaft out through the right-side of the case.

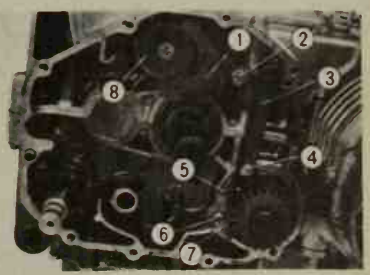
3. Remove the internal circlip, ball bearing, and collar as illustrated.

4. Evenly remove the crankcase securing bolts, then tap on the case halves with a soft mallet, and remove the lower crankcase.

Removing the shift fork guide shaft (1) and drum (2) (350/400)

5. Remove the transmission mainshaft and countershaft at the same time.

6. Remove the gearshift set plate, then remove the shift fork guide shaft and gearshift drum.

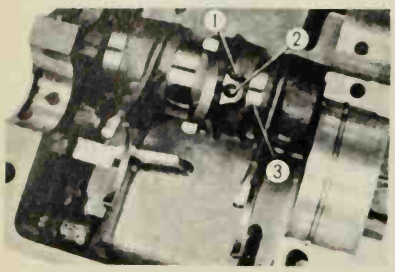


500/550

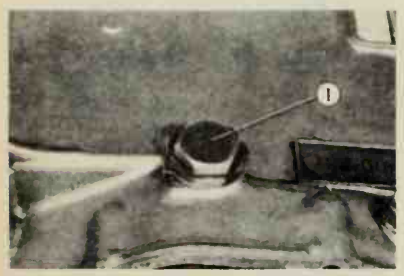
1. Remove the engine.

2. Remove the clutch assembly as described in the previous section.

3. Remove the shift lever. Depress the gearshift arm and withdraw the linkage from the right side.



4. Unscrew the shift-drum limit bolt and remove the limit arm. Take out the camplate retaining screw and remove the camplate.



External shift mechanism (500 and 550)

1. Shift drum stopper	5. Bearing set plate
2. Stopper bolt	6. Oil guide plate securing screw
3. Neutral stopper	7. Oil guide plate
4. Neutral stopper bolt	8. Cam plate

5. Take out the three 8 mm, and three 6 mm bolts on top of the rear section of the upper crankcase. Turn the engine upside down and remove the thirteen 6 mm bolts and ten 8 mm bolts which hold the crankcases together. Loosen the 8 mm bolts in reverse order of the tightening sequence. Tap the

Remove the guide pin clip (1) and pin (2) to free the drum (3) (500 and 550)

Shift drum guide screw (1) (500 and 550)

lower crankcase with a rubber mallet to break the seal and lift it off the engine.

6. Remove the neutral switch from the shift drum.

7. Unscrew the shift-drum guide screw from the upper crankcase and remove the spring, spring cap, and ball.

8. Lift the transmission mainshaft and countershaft assemblies out of the crankcase, taking care not to lose the bearing set rings. Remove the shift fork guide pin clips and pins, and pull the shift drum out of the crankcase.

650

1. Separate the crankcase halves as described in the previous section.

2. To remove the shift drum, remove the drum bearing stopper plate. Remove the cam plate and the shift drum center.

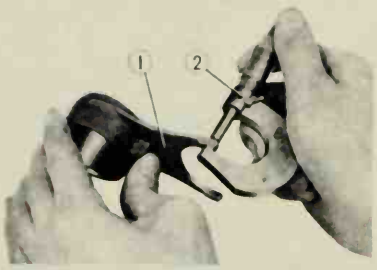
3. Remove the neutral switch.

4. Remove the shift fork shaft and forks. Remove the shift drum and bearing.

5. Remove the shift fork set pin clip. Remove the shift fork set pin and fork.

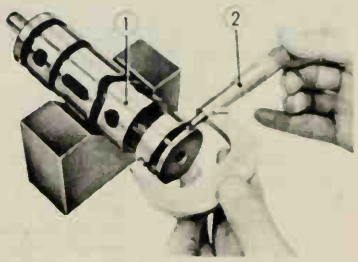
INSPECTION

All Models



1. Clean all components thoroughly in a suitable solvent, then blow dry.

2. Inspect the shift fork fingers for signs of wear or damage, measure the width of each fork finger, and the inside diameter of each fork, and replace any components worn past their serviceable limits.



3. Inspect the shift fork guide shaft for signs of wear or damage, measure the outside diameter of the shaft, and replace it if worn past its serviceable limit.

4. Inspect the shift drum for signs of wear (as indicated by bright spots along the drum grooves) or damage, measure the outside diameter of the drum, and replace it as necessary.

5. Measure the gearshift fork guide-to-gearshift drum groove clearance, and replace the components if worn past their serviceable limits.

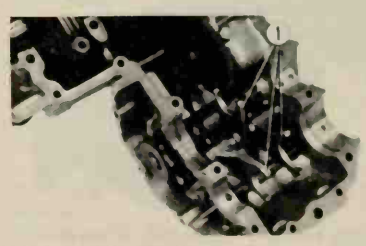
Measuring shift fork finger (1) wear with a micrometer

Measuring the shift drum (1) with a micrometer

ASSEMBLY

350/400

1. Install the shift drum and gears in the Neutral position.



2. Install the guide set plate, securing it by bending the lockwasher locking tab against the flat of the bolt.

3. Install the shift forks in their respective positions. Note that the forks are marked, "R," "C," and "L" for identification.

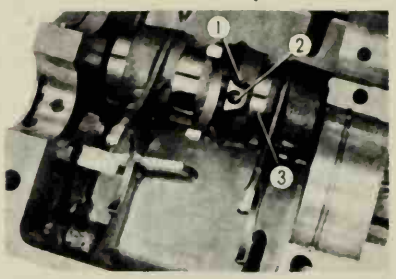
4. Make sure that the shift drum stopper, neutral stopper, and positive stopper are in their proper positions and that they work properly.

Guide set plate (1) lockwasher (2) and bolt (3) installed (350/400)

Shift forks installed (350/400)

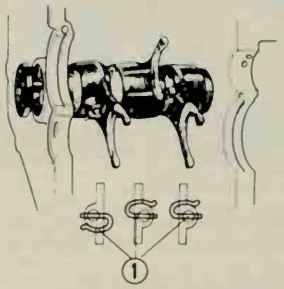
5. Rotate the spindle to check for proper operation.

6. Install the transmission components as directed in the "Transmission" section.



7. Assemble the case halves together as directed in the "Lower End" section.

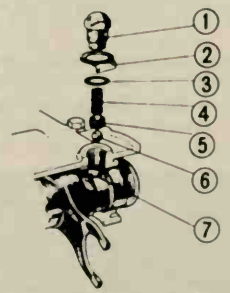
500/550



NOTE: *Modified shift-drum limit assemblies (making Neutral selection easier) are used from engine number CB 500E-1018728. Old and new parts are interchangeable. The new parts are available, along with the clutch plates mentioned in the clutch service section, in kit form, from Honda dealers so that earlier models can be updated.*

1. Place the shift forks in the crankcase as shown and install the shift drum.

2. Insert the guide pins into the forks and secure them with the clips. Be sure that

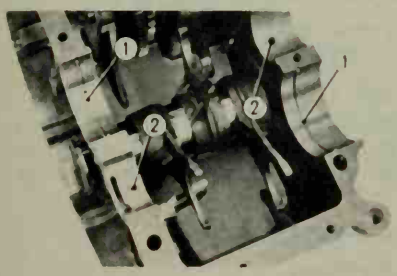


Shift drum (3), forks (2) and guide pin clips (1) installed (500 and 550)

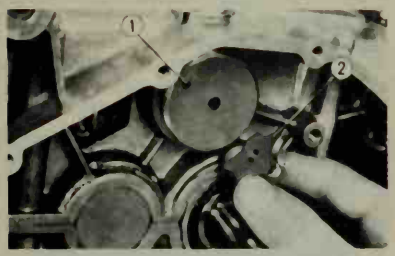
Installing the guide pin clips (1) as indicated (500 and 550)

the clips are installed in the proper direction. Refer to the accompanying illustration.

3. Align the counterbored section of the shift drum with the guide screw hole and install the steel ball, spring cap, and spring. Install the O-ring and locktab, and tighten the guide screw. Lock the guide screw in position with the locktab.

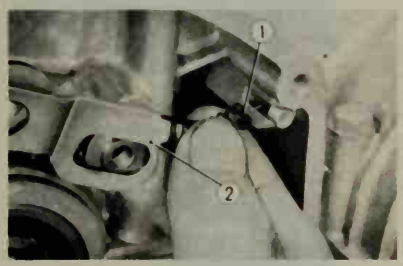


Guide screw assembly (500 and 550)



1. Guide screw cap
2. Lockwasher
3. O-ring
4. Spring
5. Spring cap
6. Ball
7. Detent

4. Align the neutral switch with the groove in the shift drum and lock in place with the 6 mm screw.



5. Replace the transmission mainshaft and countershaft assemblies in the upper crankcase, taking care to locate the bearing settings and dowel pins properly, and apply a thin coat of gasket cement to the crankcase mating surface. Carefully join the crankcase halves and install the ten 8 mm bolts. Tighten the bolts, in the correct sequence, to 17–18 ft lbs. Install and tighten the thirteen 6 mm bolts to 8 ft lbs. (Refer to "Lower End.")

Bearing set rings (1) and dowel pins (2) installed (500 and 550)

Installing the cam plate (2) on the pin (1) (500 and 550)

Installing the spring (1) on the stopper (2) (500 and 550)

NOTE: *Position the two 8 mm bolts with "9" stamped on the bolt head as shown in the tightening sequence.*

6. Turn the engine up so that it is resting on the lower crankcase and install the three 8 mm and three 6 mm bolts through the upper crankcase. Position the two 8 mm bolts marked "8" on the bolt head as indicated in the illustration.

7. Install the camplate on the shift drum, making sure that the pin in the drum and hole in the complate are aligned. Coat the threads of the retaining screw with the thread-locking compound before installing.

8. Place the spring on the end of the shift drum limit arm and install the end of the spring into the crankcase groove. Install and tighten the limit bolt, and make sure that the arm operates smoothly. If there is excessive vertical movement, the arm should be replaced.

9. Install the shift linkage and shift arm, and make sure that the arm operates smoothly in both directions. Install the shift lever.

10. Fit the clutch on the engine and reinstall the engine in the frame. Do not forget to refill the engine with oil.

650

Installation is basically the reverse of removal. Be sure to align the hole in the needle bearings with the dowel pins by aligning the marks flush with the crankcase surface. Align the ball bearing groove with the set ring.

Push the countershaft oil seal in until the oil seal lip is completely seated.

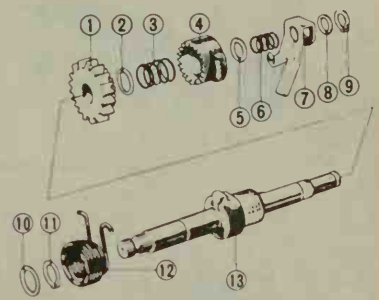
Transmission, Primary and and Kick-Starter

DISASSEMBLY

350/400

1. Follow all the steps listed in the "Shifter Mechanism" section.

Removing the primary drive sprocket (1) from the hub (2) (350/400)

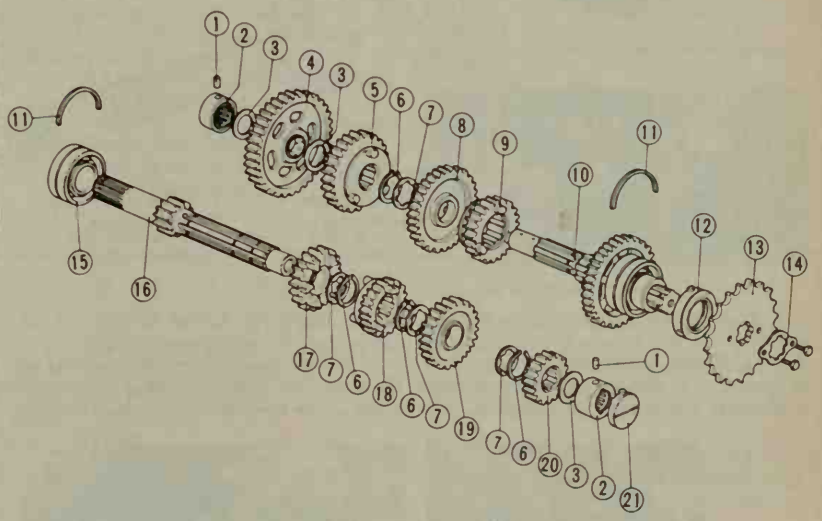


2. Remove the primary driven sprocket and the starter driven gear, then remove the driven sprocket hub from the primary driven sprocket, and remove the hub rubber dampers.

3. Disassemble the transmission shafts assemblies as necessary, keeping the components separate for assembly in their original positions.

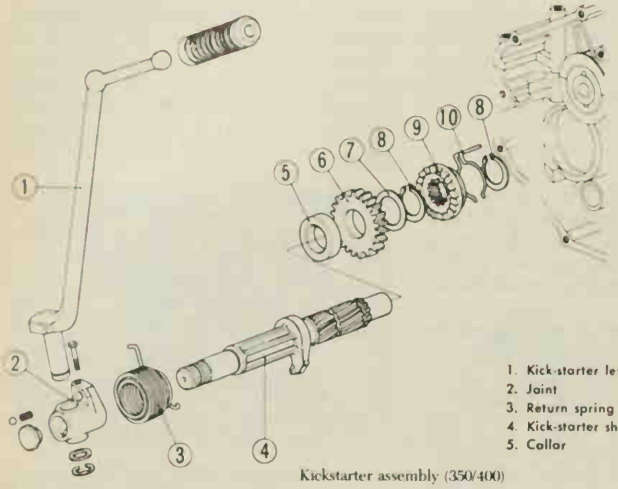
500/550

1. Follow Steps 1, 2, and 5 in the preceding section on shifter mechanism disassembly.



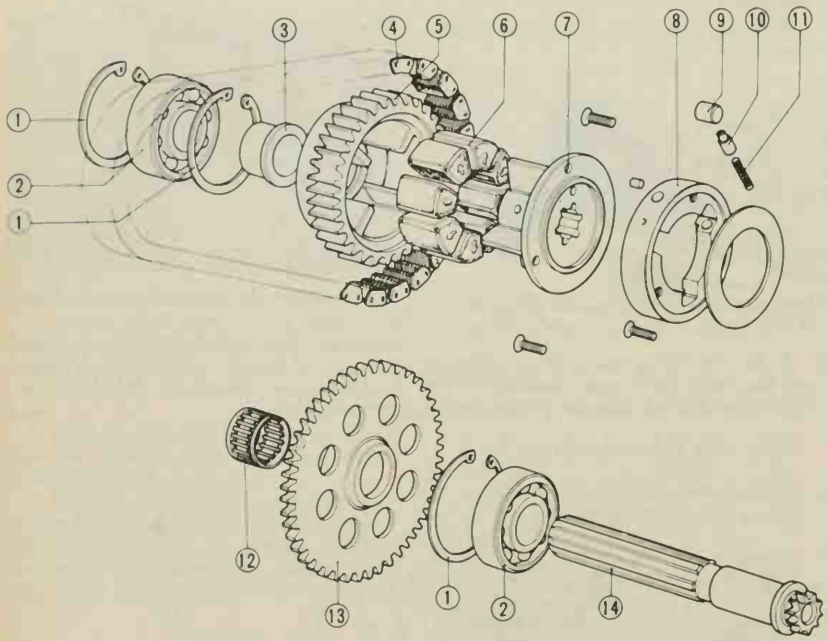
2. Lift the transmission mainshaft and countershaft assemblies out of the crankcase. Do not lose the bearing set rings.

Kick-starter assembly (500 and 550)



1. Kick-starter gear
2. Thrust washer
3. Set spring
4. Ratchet gear
5. Thrust washer
6. Spring
7. Stopper
8. Thrust washer
9. Snap-ring
10. Thrust washer
11. Snap-ring
12. Return spring
13. Kick-starter shaft

3. To remove the kick-start gear and shaft, first remove the 18 mm circlip and return spring from the end of the shaft. Remove the 12 mm circlip from the end of the shaft inside the case and withdraw the shaft from the lower crankcase.

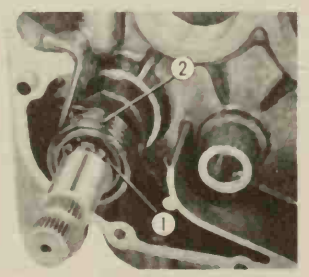


Transmission assembly (350/400)

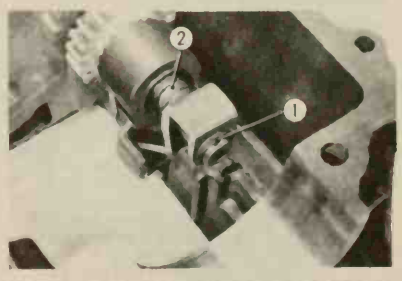
1. Gearshift fork guide pins (two), 6 mm
2. Needle bearings (two), 20 mm
3. Thrust washers (three), 20 mm
4. Countershaft low gear, 41 T
5. Countershaft fourth gear, 31 T
6. Circlips (four), 25 mm
7. Thrust washers (four)
8. Countershaft third gear, 34 T
9. Countershaft top gear, 28 T
10. Countershaft, 37 T
11. Bearing set rings (two), 52 mm
12. Oil seal
13. Drive sprocket, 17 T
14. Drive sprocket fixing plate
15. Ball bearing
16. Mainshaft
17. Mainshaft fourth gear, 27 T
18. Mainshaft third gear, 24 T
19. Mainshaft top gear, 29 T
20. Mainshaft second gear, 20 T
21. Oil seal

1. Kick-starter lever
2. Joint
3. Return spring
4. Kick-starter shaft
5. Collar
6. Kick-starter gear
7. Thrust washer
8. Snap-ring
9. Ratchet gear
10. Friction spring

Kickstarter assembly (350/400)

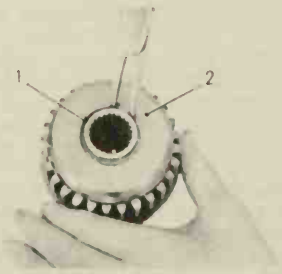


Primary shaft assembly



1. Internal circlips (three), 52 mm
2. Ball bearings (two)
3. Collar 25 x 21.8
4. Primary drive chain
5. Primary driven sprocket
6. Rubber dampers (eight)
7. Driven sprocket hub
8. Clutch outer
9. Rollers (three), 10.2 x 9.5
10. Caps (three)
11. Springs (three)
12. Needle bearing
13. Starter driven gear
14. Primary shaft

4. To remove the primary shaft, unscrew the two bolts and remove the primary shaft bearing set plate. Remove the 20 mm circlip at the end of the shaft and pull out the primary shaft using tool number 07009–32301 or a suitable gear puller. Lift out the starter clutch and primary sprocket assembly.

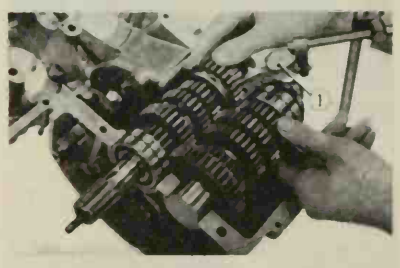


5. Pull the large primary shaft bearing off the shaft. The primary sprocket and starter clutch can be removed and separated after the primary sprocket circlip and the three 6 mm screws have been removed.

Remove the return spring (2) after removing the snap-ring (1) (500 and 550)

Remove the snap-ring (1) and then the kick-starter shaft (2) (500 and 550)

Removing the snap-ring (1) from the primary driven sprocket (2) (500 and 550)



650

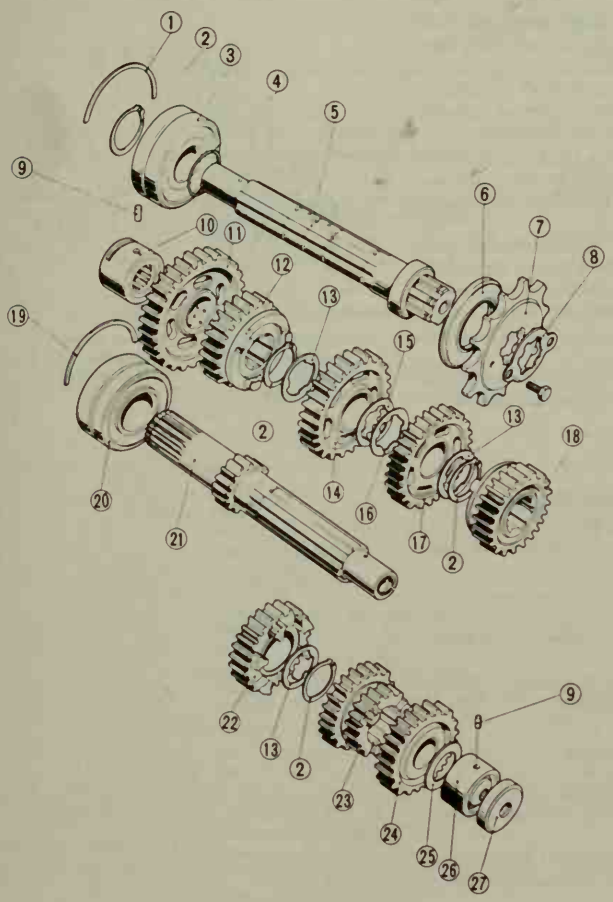
Disassembly of the transmission is straightforward. Be sure to lay out the components in the proper order as they are removed.

INSPECTION

All Models

1. Set the mainshaft and countershaft gear assemblies into the crankcase and measure backlash. Maximum acceptable backlash is 0.2 mm (0.008 in.) for all gear sets. Replace gears (mating pairs) on both shafts that exceed the limits. Inspect the dogs and replace any gears with damaged or excessively worn dogs.

Measuring backlash with a dial gauge (1)



Checking the starter clutch rollers (1)

Check the ball bearings for excessive play and make sure that the gears slide smoothly on the shaft splines.

2. Examine the damper rubbers in the pri-

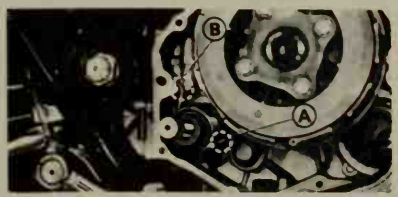
26. Needle bearing
27. Oil seal

Transmission assembly (500 and 550)

mary sprocket and replace them if they do not appear to be in perfect condition.

3. If it is necessary to replace the starter clutch needle bearing assembly or to replace other components, the housing can be removed after the three phillips head screws have been taken out.

ASSEMBLY



350/400

1. Assembly is in the reverse order of disassembly. New circlips and seals should be used, and all components should be liberally coated with a suitable assembly lubricant.

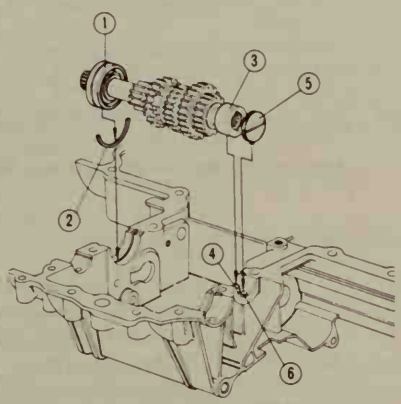
2. Note the following when installing the kickstarter assembly;

a. The hair pin section of the starter pinion friction spring is inserted into the crankcase stopper groove.

b. Hook the "A" end of the starter spring as shown, then install the kick starter assembly. The "B" end of the spring should be hooked onto the crankcase rib as illustrated.

Installing the kickstarter return spring (350/400)

c. Make sure that the starter pinion gear is properly meshed with Low gear.



3. Note the following when assembling the mainshaft assembly;

a. Install the ball bearing with the bearing set ring installed in its groove.

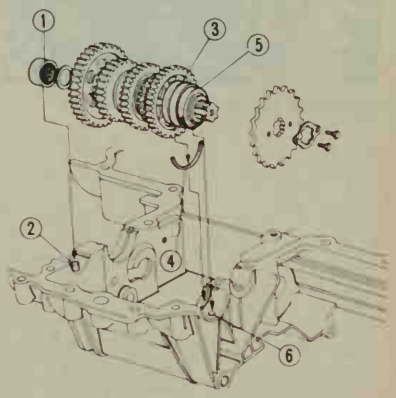
b. Install the needle bearing so that its guide pin fits in the guide pin hole.

c. Install the oil seal so that its dowel fits into the pin hole in the upper crankcase half.

4. Note the following when assembling the countershaft assembly;

Installing the mainshaft assembly (350/400)

1. Ball bearing
2. Bearing set ring
3. Needle bearing
4. Guide pin
5. Oil seal
6. Seal pin hole



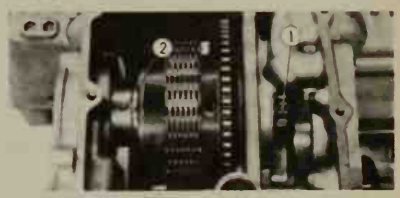
a. When installing the needle bearing, make sure that the crankcase guide pin is seated in its pin hole.

b. Install the ball bearing with its ring groove fitted onto the ring installed in the upper case half.

c. Install the oil seal so that its pin is seated in the pin hole in the upper case.

d. After both shafts are installed in the case, check the transmission for smooth operation by rotating the crankshaft.

5. If the clutch outer body has been disassembled, stake each of the three flat screws, as illustrated, after screwing them in.



Installing the countershaft assembly (350/400)

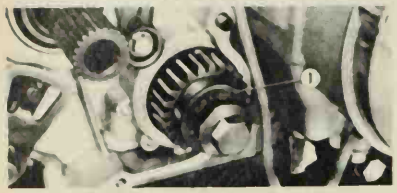
1. Needle bearing
2. Guide pin
3. Ball bearing
4. Bearing set ring
5. Oil seal
6. Oil seal pin hole

Peen the three screws (1) if they have been removed (350/400)

Installing the primary shaft and collar (350/400)

6. Insert the primary shaft through the right-side of the case after the case halves have been assembled, but not secured, then install the collar.

7. The primary shaft ball bearing will have to be driven into place with a suitable drift, and then secured with the 25 mm internal circlip.



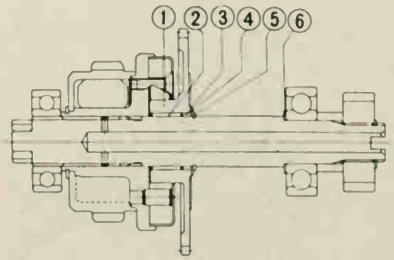
Installing the bearing (1) and circlip (2) (350/400)

8. Secure the case halves as directed in the "Lower End" section.

9. Install the primary shaft lockwasher so that the word "OUTSIDE" faces outward.

500/550/650

1. Assemble the starter clutch housing and clutch hub, coating the threads of the three screws with thread-locking compound. Stake the screws with a punch, as previously illustrated, to prevent loosening.



Lockwasher (1) correctly installed

2. Assemble the primary shaft components onto the shaft in reverse order of removal. Refer to the accompanying illustration.

e. Assemble the kick-starter components onto the shaft and install in the crankcase. Refer to the exploded view of the components for order of assembly.

4. If the mainshaft and countershaft gears have been removed, *do not reuse the old circlips*. Take care to install the new circlips with the smooth edge against the thrust washer. Refer to the exploded view of the components for order of assembly.

5. Follow Steps 5, 6, and 10 in the preceding section on shifter mechanism assembly.

Primary shaft assembly (500 and 550)

LUBRICATION SYSTEM

OIL PUMP

Removal and Installation

The oil pump can be removed without moving the engine from the frame. The procedure is as follows:

1. Drain the engine oil.
2. Remove the starter motor cover (500/550).
3. Remove the shift lever and left footrest.
4. Remove the left crankcase cover. A hammer-driven impact wrench will aid in re-

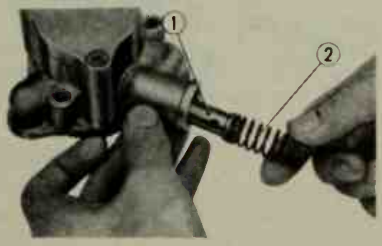
Oil pump mounting bolts (1 and 2)

moving the screws without damaging the heads.

5. Disconnect the wire from the pressure switch, located on top of the pump.

6. Remove the pump mounting bolts and withdraw the pump.

Installation is in reverse order of removal. The following points should be observed:



1. Use new gaskets and O-rings.

2. Do not forget to refill the engine with oil.

Oil Pump Service

DISASSEMBLY

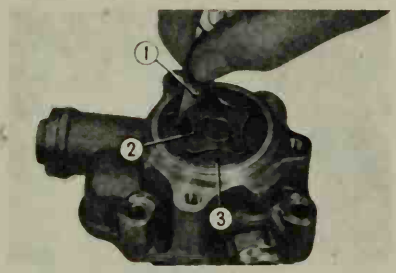
1. Remove the cap and withdraw the relief valve and spring.

Removing the relief valve (1) and spring (2)

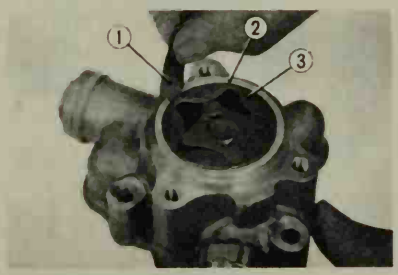
2. Remove the three screws and the side-cover, exposing the rotors. Withdraw the rotors and mark them as shown (if not already marked).

3. Remove the drive pin and withdraw the drive gearshaft.

4. Unscrew the pressure switch from the pump body.

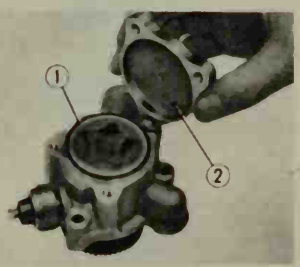


Rotor marks must be aligned when installing rotors



INSPECTION

1. Measure the clearance between the inner and outer rotors, as illustrated. Replace both rotors if clearance exceeds 0.3 mm (0.0118 in.) (350/400) or 0.35 mm (0.013 in.) (500/550) or 0.15 mm (0.006 in.) (650).



2. Measure the clearance between the outer rotor and housing. If clearance exceeds 0.35 mm (0.013 in.), the complete pump should be replaced.

Measuring clearance between the inner (2) and outer (3) rotors with a feeler gauge (1)

Checking clearance between the pump body housing (2) and the outer rotor (3) with a feeler gauge (1)

Replace the O-ring (1) before installing the cover (2)

Install the O-ring collar (1) and the O-rings (2 and 3) before bolting up the pump

3. Examine all components for damage and stress cracks.

4. Examine the relief valve for wear and replace if necessary. It is a good idea to replace the spring at this time to be sure of maintaining proper oil pressure.

ASSEMBLY

Assemble in the reverse order of disassembly.

1. Do not reuse old O-rings.

2. Lubricate all moving parts with oil before installing.

3. Be sure that the drive pin is securely installed in the shaft.

4. When installing the rotors, make sure that the mark in the side of each faces in the same direction. The rotors may be installed with the marks facing either toward or away from the side cover.

5. Use extreme care when installing the pressure-relief valve cap. *Overtightening will cause the cap to fracture.* Tighten to 7.5–10 ft lbs.

FUEL SYSTEM

NOTE: *Carburetor operation and inspection procedures are explained in detail in the "General Information" section.*

CARBURETORS

All Models (1971–80)

REMOVAL AND INSTALLATION

1. Remove the fuel tank.

2. Raise the seat and remove the air filter element. Unbolt and remove the air filter housing.

3. Disconnect the throttle cables from the carburetor linkage.

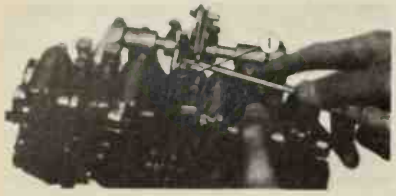
4. Loosen the air filter intake clamp at each carburetor.

5. Loosen the carburetor-to-intake tube clamps and withdraw the carburetors toward the rear.

Installation is in reverse order of removal. The following points should be noted:

1. Make sure that the carburetors are securely clamped to the intake tubes. Use new clamps if necessary.

2. Check carburetor adjustment and synchronization after installation as described in "Tune-Up."



Oil Pump Specifications

	350/400		500/550		650	
	Standard (mm/in.)	Serviceable Limit (mm/in.)	Standard (mm/in.)	Serviceable Limit (mm/in.)	Standard (mm/in.)	Serviceable Limit (mm/in.)
Rotor-to-rotor clearance

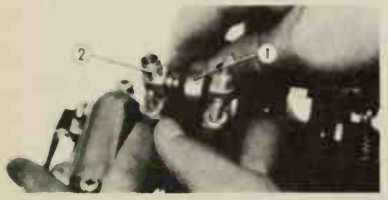
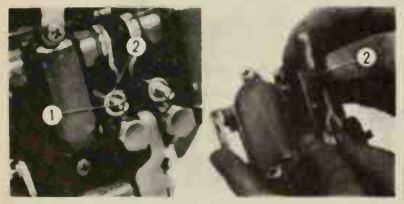
na: not available

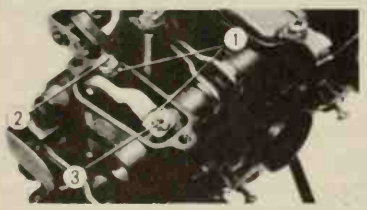
DISASSEMBLY



1. Remove the throttle return spring. Be careful not to damage the spring hook.
2. Unscrew the nuts and remove the dust plate, as illustrated.
3. Remove the adjuster holders from the linkage arms.
4. Unbolt and separate the carburetors from the mounting plate.
5. Separate the carburetors. Do not misplace the connecting tubes.

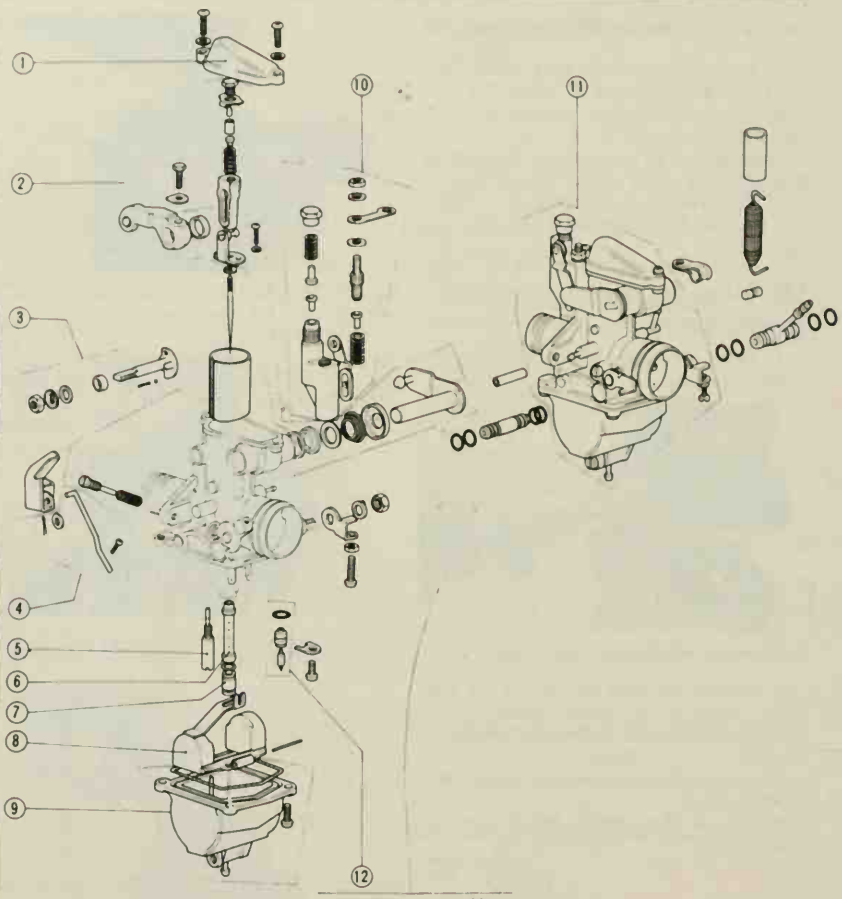


Removing the throttle return spring (1)



Remove the nuts (1) and dust plate (2), then loosen the capnuts (3)

Remove the link arm (1) from the adjuster holders (2)

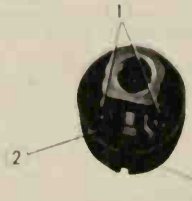


Remove the adjuster screw (1) from the adjuster holders (2)

Bend back the lockwasher (1) locking tabs, then remove the bolts (2 and 3)

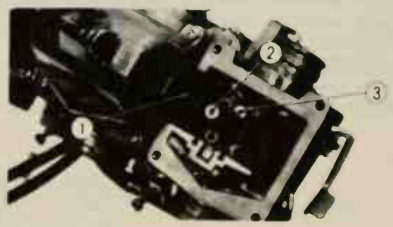
NOTE: *Disassembly procedure from this point on is given for one carburetor, but applies to all four. Keep each carburetor and its components separate from the others; do not interchange parts between carburetors.*

6. Remove the two screws and lift off the carburetor cap.

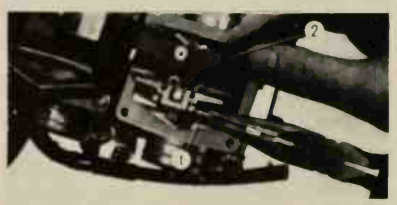


Carburetor assembly

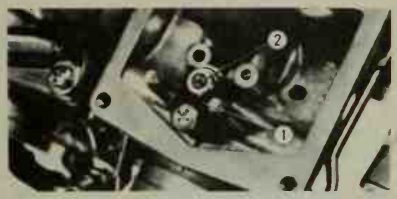
1. Carburetar cap	4. Choke rod	7. Main jet	10. Adjuster holder
2. Throttle slide linkage	5. Pilot jet	8. Floats	11. Carburetar (complete)
3. Chake arm	6. Needle jet	9. Float bawl	12. Float needle and seat



7. Position the throttle slide to full-open and bend back the two locktabs.
8. Remove the bolt from the shaft end and remove the linkage arm in direction "A" using a screwdriver.
9. Loosen the bolt on the throttle slide about one-half turn and pry the linkage arm loose.
10. Remove the two screws and rotate the slide plate one-quarter turn in either direction to align the tab on the plate with the groove in the shaft. Remove the plate.
11. Remove the jet needle from the throttle slide.
12. Remove the float bowl.
13. Remove the leaf spring and unscrew the main jet.
14. Pull out the float hinge pin and remove the float.



Removing the link arm (1) and throttle shaft (2)



Remove the screws (1) and turn the plate (2) 90° to separate it from the slide (3)

Remove the leaf spring (1), main jet (2), and pilot jet (3)

Remove the float arm pin (1), then remove the float (2)

Remove the clip plate (1) and needle seat and needle (2)

15. Remove the screw and clip plate, and withdraw the float needle and seat.

16. Remove the main jet tube, low-speed jet, and air screw.

CLEANING

Clean all metal parts in a solvent or carburetor cleaner. Use compressed air to dry parts. Blow all fuel jets clear. Never insert anything into the jet bores to clear them if clogged.

INSPECTION

1. Check the throttle slide surfaces for scoring or signs of wear. The slide should be smooth. The movement of the slide in the carburetor body should be very easy.

2. Examine the jet needle for wear along the tapered portion as indicated by bright spots or unevenness of the taper. Also check the needle for nicks, and replace it if any damage is noted. Be sure that the needle clip is repositioned in the original groove if removed.

3. After many miles the needle and needle jet should be replaced, as these parts are subject to wear. Wear of these components may show up as a rich running condition in the mid-throttle range. If the needle seems worn, it would be best to replace the needle jet as well.

4. Check the float needle for wear of the tip or foreign matter and replace if necessary. Check the needle seat for corrosion or foreign matter. Clean off the seat if only dirty. Corroded needle seats should be replaced.

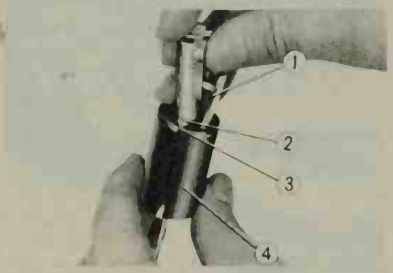
5. If brass floats are fitted, check the floats for punctures by shaking them close to the ear and listening for any gas inside. Replace any float assembly with this condition.

6. Check the carburetor body and the float bowl for stress cracks.

7. Inspect the pilot air screws. The taper of the screws should be very even. Replace if the screw tip is blunted.

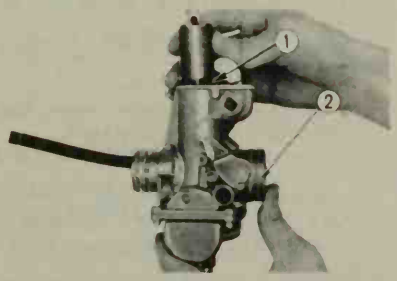
Assembly

Assembly is the reverse of the disassembly procedure. The following points should be noted:



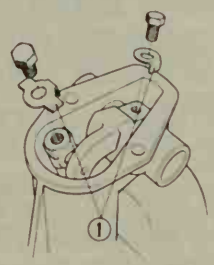
1. Use new gaskets and O-rings.

2. The float should be positioned so that when the float arm just touches the end of the float needle, the distance from the top of the floats to the float bowl mating surface on the carburetor is 12.5 mm (0.5 in.) on the 650, 21 mm (0.83 in.) on the 350/400 or 22 mm (0.89 in.) on the 500/550. Bend the float arm in the desired direction if adjustment is necessary. Make sure that the floats are even. Note that this measurement must be made without the float bowl gasket in place.

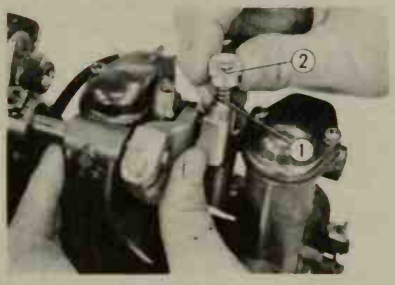


NOTE: *A special float level gauge (part number 07144-99998) is available from Honda dealers.*

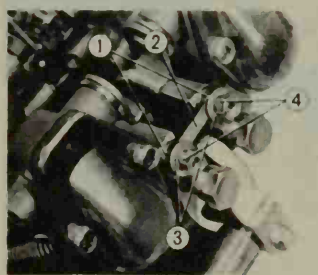
3. Do not overtighten the jets when installing them in the carburetor body.



4. Make sure that the jet needle is installed in the same position as when it was removed. Changing needle position in the slide will affect running at mid-range throttle openings.



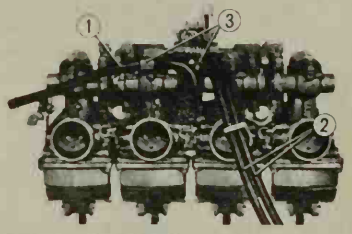
Install the spring washers (3), then position the plate (1) and push it down. Rotate the plate 90° toward the link arm and secure it with the mounting screws (2)



Make sure that the cutaway section (1) of the slide is toward the choke valve (2)

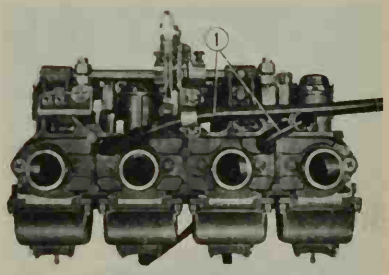
Install the locktabs (1) as shown

Secure the spring (1) with the capnut (2) on the adjuster holders



Install the washers (1), dust plate (2), washers (3), and nuts (4) in that order

5. To install the adjuster holder (if removed), first insert the spring and spring seat. Open the throttle slide about halfway and install the holder onto the shaft while holding the spring seat down with a thin screwdriver.



6. Install the locktabs as shown.

7. Do not forget the spring under the capnut on the adjuster holders.

8. Install the special washers and dust plate as shown.

Fuel line routing (350/400)

Fuel line routing (500/550)

9. Route the fuel lines as shown.

10. Open the throttle lever until it contacts the stop screw. The throttle slide-to-bore clearance should be 0–1.0 mm (0–0.04 in.). Adjust the clearance, if necessary, by turning the stop screw.

1981 Models

REMOVAL AND INSTALLATION

NOTE. *The carburetors must be removed as an assembly.*

1. Turn the petcock "off," disconnect the fuel line at the carburetor.

2. Remove the left and right side covers.

3. Remove the air cleaner assembly.

4. Loosen the carburetor manifold clamps. Remove the carburetors as an assembly. Disconnect the choke and throttle cables.

CAUTION: *Remember that the carburetors are full of gasoline. Drain the float bowls into a suitable container by loosening the drain screws.*

5. Installation is the reverse of removal. Note the following points:

a. Do not interchange the "pull" and "push" throttle cables. The "pull" cable is closest to the engine.

b. Be sure that the carburetors are firmly seated in the manifold spigots.

c. Be sure that the air cleaner tubes are not twisted or folded up so as to block the carburetor intakes.

d. Adjust the throttle cables, butterfly synchronization, idle and fast idle adjustments.

e. Be sure that all fuel line connections are tight and secured with the safety clips. Before operation, turn on the fuel and check for leaks.

DISASSEMBLY

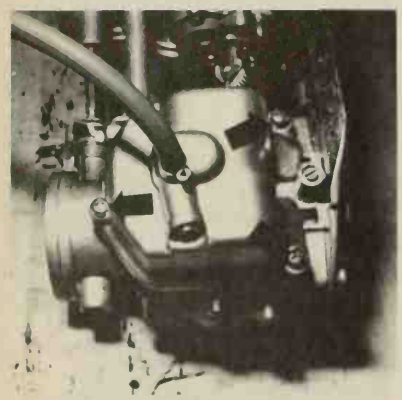
1. Loosen the locknut, and back off the butterfly synchronization screw.

NOTE: *The slides will have to be synchronized after assembly.*

2. Disconnect the spring from the choke lever.

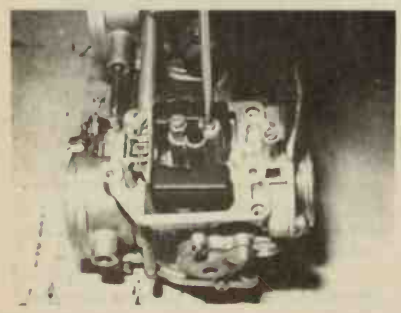
3. Remove the phillips head screws and take off the rear and the front stays.

4. Separate the carburetors, noting that the fuel connecting pipe and the choke spring will come loose. The pipe has o-rings on both sides. Do not lose them.



From this point, disassembly is given for one carburetor, but applies to both.

5. Unscrew and remove the carburetor tops. Take out the spring, and the throttle slide assembly with jet needle.



The jet needle can be removed from the throttle slide after taking off the full open stopper and unscrewing the needle set screw.

Removing the cap and spring

Float bowl screws (arrows)

Removing the secondary main jet

Removing the needle jet

6. Remove the seal ring from the top of the carburetor body.

7. Remove the air jet cover.

8. Remove the float bowl screws, and very carefully take off the float bowl.

9. Unscrew and remove the primary and secondary main jets.

10. Remove the slow jet plug.

NOTE: *The slow jet itself is a press-fit in the carburetor body and cannot be removed.*

11. Remove the primary nozzle which is beneath the primary main jet.

12. Remove the needle jet holder.

13. Unscrew and remove the pilot screw. Note that the pilot screw will have to be adjusted during reassembly. Note the spring and o-ring on the jet.

14. Use a needle-nosed pliers to pull out the float pin. Remove the floats. Remove the float needle.

15. Remove the air cut-off valve cover and take out the spring. Remove the diaphragm very carefully and take out the o-ring as well.

INSPECTION

1. Clean the carburetor body and float bowl in a carburetor cleaner or solvent and dry thoroughly.

2. Use compressed air to blow air and fuel passages clear.

3. Clean all fuel jets in the same manner.

CAUTION: *Do not insert anything into the jet passages to clear them; use air pressure only.*

4. Inspect the carburetor body for any vibration or stress cracks.

5. Check the condition of the throttle slide. Smooth movement of the slide on the carburetor body is imperative. If the slide sticks or binds at any point from full closed to wide open, replace it.

6. Inspect the needle jet and the needle. The needle must be free of nicks or score marks along its tapered portion. More often, however, these components will need to be replaced because of normal wear. As the throttle slide moves up and down while the machine is in operation, the needle is rubbing against the jet. Eventually, these components will wear enough to cause a noticeable rich running condition in the mid-throttle range. If this occurs, both the needle and the jet should be replaced. If the components are more than four years old, new ones should be fitted before attempting to tune the carburetor, or taking remedial action to correct a rich condition.

7. Check the throttle slide for scoring. Replace it if any is noted.

8. Inspect the tip of the float needle and the needle seat for dirt or corrosion. Check the needle tip for wear. If worn, the needle should be replaced.

If there is any corrosion or deposits evident on the needle seat, the deposits must be removed, or the parts replaced.

NOTE: *Do not attempt to clean the needle or needle seat by lapping one against the other.*

To check the efficiency of the float needle valve, proceed as follows:

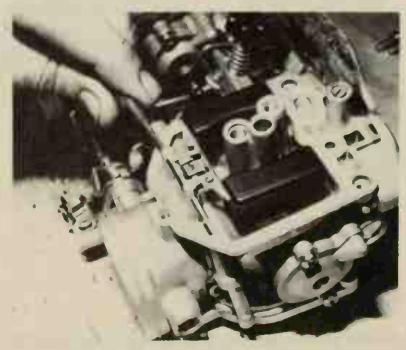
a. With the carburetor assembled except for the float bowl, connect it to its fuel line;

b. Place a number of dry rags beneath the carburetor, and hold it upright (in its normal operating position) with one hand;

c. With the other hand, gently raise the float assembly until the float needle is seated. Have an assistant turn the fuel petcock on;

d. If the needle and seat are in good condition and forming a good seal, no gasoline will flow out of the carburetor;

e. If a leak is noted, replace the needle and seat.



CAUTION: *While performing this test, be sure that adequate precautions are taken in the event of spilling.*

The float level should be checked prior to assembly. Refer to chapter 3.

9. Check that the tapered portion of the pilot screw is smooth and clean. Replace it if it is crushed or blunted.

10. Inspect the float bowl for a warped gasket surface, or stress cracks (especially around the screw holes).

11. Check the air cut-valve diaphragm for condition. Replace it if ripped or punctured.

Pushing out the float pivot pin

ASSEMBLY

Assembly is basically the reverse of the disassembly procedure. Note the following points:

1. Always use new gaskets and O-rings.

2. Exercise care when installing jets—they are made of soft brass and are easily damaged if overtightened.

3. Be sure that the float pivot pin is properly seated, and that the floats pivot freely.

4. Tighten the float bowl screws slowly and evenly. Be sure that the O-ring is seated in its groove before installing the float bowl.

5. When joining the two carburetors together, be sure that the o-rings are in place on either end of the fuel pipe. Fit the pipe

into the carbs carefully to avoid damage to the o-rings.

6. Do not forget the choke relief spring.

CARBURETOR SEPARATION

Although almost all routine work can be performed with the carburetors attached together, the units may have to come apart. If this is desired, proceed as follows:

1. Unhook the choke relief spring from the shaft arm between carburetors Nos. 3 and 4.

2. Loosen the synchronization screw locknuts. Turn the synchronization screws in until they seat and note the number of turns so that they can be roughly repositioned when assembling. Then back the screws out until there is no tension.

3. Remove the rear bracket which is held to each carburetor by two screws.

4. Remove the front bracket.

5. Separate the carburetors between units Nos. 2 and 4. Pull them straight apart to avoid damage to the lines.

6. File the staked ends of the choke valve screws. Remove the screws. They must be replaced with new ones on assembly.

7. Remove the fuel line holder from the No. 1 carb. Separate the carbs. Be careful to pull them straight apart to avoid damage to the fuel and air lines.

8. After noting the spring position, remove the choke relief spring from the choke linkage. Remove the choke shaft.

NOTE: *The choke shaft, valves, and screws cannot be reused.*

9. Remove the cotter pin from the accelerator pump rod. Remove the plain washers, spring and collar.

10. Remove the fast idle adjusting arm bolt.

11. Remove the fast idle adjusting arm and springs.

12. Remove the accelerator pump rod. Drive out the throttle linkage retaining pin. Remove the throttle linkage.

13. Assembly is basically the reverse of disassembly. Note the following points:

a. assemble one pair of carbs at a time;

b. use new o-rings on the fuel line joints;

c. lubricate the o-rings with a bit of grease before assembly;

d. install the fuel line, accelerator pump joint and air vent pipes on the No. 3 unit. Install the choke dust tube. Loosen the synchronization adjusting screw until there is no tension. Insert the No. 3 unit throttle link between the plain washers. Assemble carburetors Nos. 3 and 4.

NOTE: *The large washer should be positioned on the spring side.*

e. assemble carburetors Nos. 1 and 2 in the same manner;

f. insert new choke shafts and assemble the linkage;

g. install the front bracket screws, but do not tighten them;

h. place the carbs on a flat surface with the float bowls facing up. Press them together and tighten the screws evenly by tightening the left side screw on each carburetor first, then going back and securing the right side screw on each one. Tighten the screws gradually to 3–4 ft. lbs.

NOTE: *After securing the screws, check for smooth choke shaft operation. Recheck alignment if operation is not satisfactory.*

i. fit the rear bracket using the same procedure. Tighten the rear bracket screws to 2–3 ft. lbs.

j. install the thrust springs between No. 1 and 2 and between Nos. 3 and 4 throttle linkages;

k. turn each synchronization adjusting screw to its original position as noted during disassembly;

l. adjust the throttles so that the distance between the by-pass hole and the throttle plate is the same for each unit;

m. open the throttle slightly, then release. Be sure that the throttle linkage is smooth and free of binding;

n. hook the choke relief spring to the choke shaft between units 3 and 4. Install the choke valves, but do not tighten the screws; be sure that choke valve operation is smooth, then tighten the valve screws to 5–11 ft. lbs. Fold the tabs on the lockwasher up. Recheck choke and throttle operation.

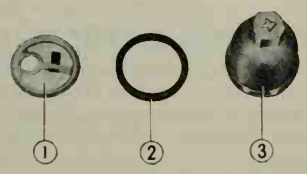
FUEL PETCOCK

REMOVAL, CLEANING, AND INSPECTION

1974 and Earlier Models

1. Turn the petcock lever to "stop" and disconnect the fuel lines.

2. Raise the seat, and raise and support the rear of the gas tank.



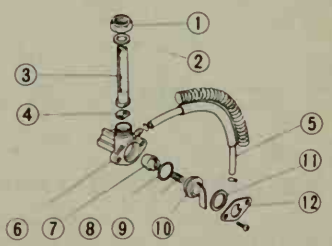
3. Unscrew the sediment bowl from the petcock, being careful of the gasoline which will also spill out.

4. Remove the O-ring and filter.

5. Remove the two screws which secure the petcock body to the gas tank, and remove the petcock.

6. Clean all components in gasoline and dry; then inspect for damage.

7. When assembling the petcock, it is advisible to use new gaskets and O-rings.



Fuel petcock filter screen (1), O-ring (2) and sediment bowl (3)

8. After installing the petcock, check for proper gas flow as well as leaks.

1975 and Later Models

The petcock filter screen is inside the gas tank.

1. Disconnect the fuel lines from the petcock. Remove the tank from the machine, and drain off the gas.

1975 and later petcock

1. Nut	7. Valve
2. Gasket	8. O-ring
3. Filter screen	9. Spring
4. Seat	10. Lever
5. Fuel line	11. Washer
6. Petcock body	12. Plate

2. Unscrew the securing nut and carefully take out the petcock. Remove the securing nut and filter from the petcock.

3. Wash the filter in a solvent. Replace the filter if it is punctured or badly clogged. Check the condition of the gasket and replace it if it is crushed or nicked.

Carburetor Specifications

	350	400	500	550	650 (79–80)	650 (81)

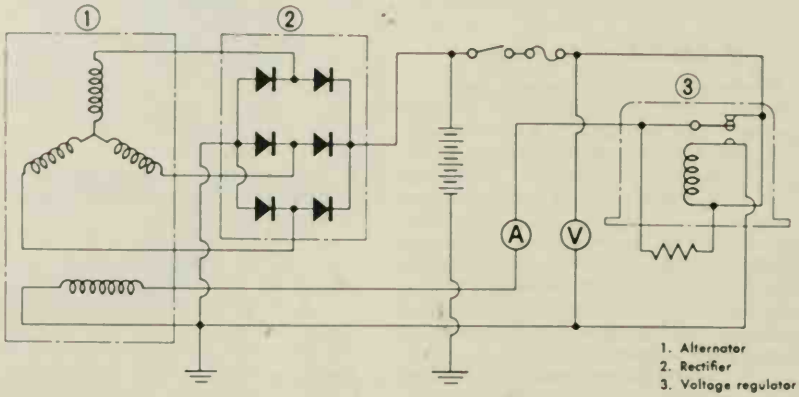
ELECTRICAL SYSTEMS

ALTERNATOR OUTPUT TEST

1. Check the state of charge of the battery. If battery voltage is less than 12 volts, or if specific gravity of the electrolyte is less than 1.26, recharge the battery before proceeding with the test.

2. The test is performed using an ammeter and a voltmeter. Connect the ammeter as follows: disconnect the positive (+) battery cable and connect it to the positive side of the ammeter; connect the negative (−) side of the ammeter to the positive battery terminal. Connect the voltmeter as follows: connect the positive side of the ammeter to the positive battery cable, and ground the negative voltmeter lead on the engine.



Connect the red/white (1) lead to the positive side of the ammeter (2), and connect the voltmeter (3) to the positive battery (4) terminal and ground

1. Red/white lead
2. Ammeter
3. Voltmeter
4. Battery

3. Start the engine and check the amperage and voltage output of the alternator under both day riding (lights off) and night riding (lights on) conditions. If the readings obtained are noticeably greater or smaller than those in the accompanying table, adjust the regulator. Slight variation is acceptable due to the effect of the state of charge of the battery upon alternator output. If alternator output is satisfactory but the battery has discharged during use, refer to the section on testing the rectifier.

NOTE: *The 650 is tested with the headlight on "High" beam. The readings should show initial charging beginning at 1,650 rpm and should indicate a minimum of zero amps/14 volts at 5,000 rpm.*

1. Alternator
2. Rectifier
3. Voltage regulator

Regulator test (350/400)

REGULATOR ADJUSTMENT

350/400

NOTE: *Perform the following tests with a fully charged battery.*

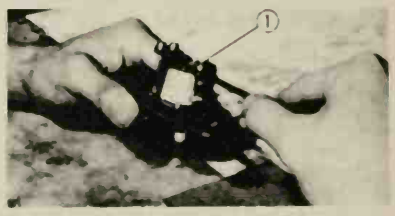
1. Connect a DC voltmeter from the regulator ignition terminal to ground, then disconnect the white lead from the field terminal (F), and connect an ammeter between the lead and the terminal.

2. Take a field current reading with the engine idling, and compare it with the Mode I limits given in the accompanying chart. If the value found exceeds the value given, either the regulator or alternator field coil is defective.

Mode	Field Current	Voltage
I (idle)	2.4–2.6A	to 13.2V
II	1.2–1.3A	13.5–14.5V
III	0–1.2A	14.0–15.0V

3. Slowly increase the engine speed until the ammeter needle deflects to read half the Mode I value, and compare the reading at the moment of deflection with the Mode II value given in the accompanying chart.

4. Increase the engine speed to at least 4,000 rpm, and note the maximum voltage reading. The field current and voltage should agree with the Mode III value given in the chart. If the field current doesn't decrease as voltage increases, the regulator is defective. If the field current and voltage values do not agree with those given in the chart, the regulator should be adjusted. If the voltage is in excess of 15.0V, the system is overcharging.



5. Armature and angle gap are adjusted simultaneously by bending the holder until gaps of 0.012 in. (0.3 mm) 0.08 in. (0.2 mm) respectively are attained.

6. Adjust the point gap by bending the lower point bracket until a gap of 0.018 in. (0.45 mm) is attained.

7. Correct the voltage readings by bending the adjusting arm *up* to increase the charging voltage, or *down* to decrease it.

Adjusting gap by bending the adjusting arm

Checking clearance between the top point (1) and the lower one

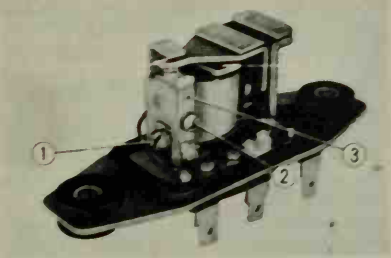
500/550

NOTE: *Perform the following tests with a fully charged battery.*

1. Disconnect the three wires at the regulator, marking them so that they can be replaced on the same terminals. Take out the two mounting bolts and remove the regulator unit.

2. Remove the two screws and take off the regulator cover.

3. Examine the condition of both sets of contact points. If dirty or pitted, they may be cleaned up with fine emery paper.



4. Measure the core gap with a feeler gauge. If the gap does not measure within 0.024–0.040 in. (0.6–1.0 mm), loosen the

Alternator Output (350/400)

Engine rpm	1000	2000	3000	4000	5000	6000	7000	8000
Charging current (amps)								
Night riding (headlight on)	1.6	1.9	2.0	1.8	1.6	1.5	1.4	1.4
Day riding (headlight off)	——	——	4	2.6	2.0	1.6	1.4	1.4
Battery terminal voltage	12.5	14.2	15	15	15	15	15	15

Alternator Output (500/550)

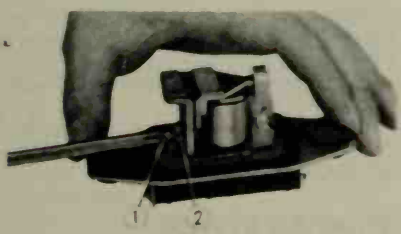
Regulator adjusting points

A. Core gap
B. Point gap
1. Core gap adjusting screw
2. Point gap adjusting screw
3. Moveable contact



core gap adjusting screw and move the point body up or down as required.

5. Measure the gap of the upper point set in the same manner. The points should be gapped at 0.008 in. (0.2 mm). To adjust the gap, loosen the adjusting screw and move the lower contact up or down as required.

6. Temporarily install the regulator with one of the mounting bolts, leaving the cover off. Connect the three wires.

7. Loosen the voltage adjusting screw locknut. If the alternator output test showed insufficient output, turn the voltage adjusting screw clockwise about one-quarter turn. If the test showed output to be excessive, turn the screw counterclockwise about one-quarter turn. Tighten the locknut and rerun the alternator output test. Readjust the screw as necessary to obtain satisfactory alternator output.

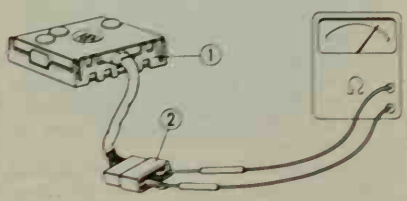
8. If alternator output is unstable or excessive after the regulator has been adjusted properly, chances are that the regulator is faulty. If alternator output is insufficient and

Loosen the locknut (2) and rotate the adjusting screw (1) to correct voltage

cannot be brought up to specification through regulator adjustment, the alternator itself should be suspected. Before proceeding any further, make sure that the battery is producing at least 12 volts at the terminals, and that none of the cells are dead or have a noticeably lower specific gravity than the rest. If the battery checks out all right, replace the regulator or check into the alternator (refer to the "Alternator Service" section), as indicated.

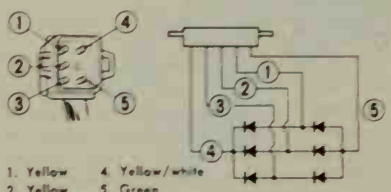
TESTING THE RECTIFIER

Except 650



If alternator output is satisfactory but the battery discharges as the engine is running, it is quite possible that the rectifier is not functioning properly. (This is assuming, of course, that the battery is not old and tired or has one or more bad cells.) Before removing and testing the rectifier, make sure that it is solidly mounted on the frame. The rectifier is grounded through its mounting and will not operate without a good ground.

CAUTION: *Do not loosen or tighten the nut that holds the rectifier unit together, as this will adversely affect operation of the rectifier.*



1. To test the rectifier, first pull apart the plastic connector, unscrew the mounting nut, and remove the rectifier unit. Inside the rectifier are six diodes which, if functioning properly, will allow electricity to pass in only one direction.

2. Check the diodes, using either a multimeter or a test light and the motorcycle battery. If the test light and battery are to be used, simply run a length of wire off one of the battery terminals and connect one of the test light leads to the other terminal. The two free wire ends will be used to check electrical continuity of the diodes.

3. Connect one of the leads to pin number 4 in the connector block and touch the other lead to pins 1, 2, and 3, in turn. Now, reverse the leads and repeat the procedure. The test

Rectifier (1) with coupler (2) attached to tester

1. Yellow
2. Yellow
3. Yellow
4. Yellow/white
5. Green

Schematic diagram of rectifier showing connector pin arrangement

light should light (or the meter needle respond) in one direction only.

4. If all is well so far, connect one of the leads to pin 5 and touch the other to pins 1, 2, and 3 again. Reverse the leads, as before, and repeat.

5. Continuity in both directions or in neither direction (when reversing the leads) indicates a defective diode, in which case the rectifier unit must be replaced.

NOTE: *On an ohmmeter, "continuity" will be indicated by a resistance of 5–40 ohms. "No continuity," by a resistance of 100 or more ohms.*

The diodes are quite susceptible to failure from excessive heat and electrical overload. Observe the following precautions to avoid rectifier failure:

a. Do not use high-voltage test equipment to test the rectifier diodes.

b. Do not run the engine at high rpm with the rectifier "P" terminal disconnected, or else the high voltage that is produced will damage the rectifier.

c. Do not quick-charge the battery (high-output charging equipment) without first disconnecting one of the battery cables.

REGULATOR/RECTIFIER (650)

1979–1980

Testing for the unit regulator/rectifier is done with an ohmmeter.

Resistance between green and any yellow lead should be 5–40 ohms.

Resistance in the reverse direction should be at least 2,000 ohms.

Resistance between the red/white lead and any yellow lead should be 5–40 ohms.

Reversing the probes should yield at least 2,000 ohms.

1981

Regulator and rectifier are tested separately. Refer to the following charts.

Rectifier

(+) \ (−)	Red/White	Green	Yellow 1	Yellow 2	Yellow 3
Red/White		∞	∞	∞	∞
Green	0.5–50		0.5–50	0.5–50	0.5–50
Yellow 1	0.5–50	∞		∞	∞
Yellow 2	0.5–50	∞	∞		∞
Yellow 3	0.5–50	∞	∞	∞	

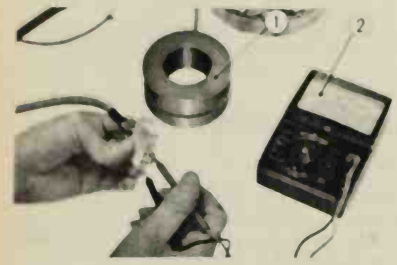
Regulator

(+) \ (−)	Black	White	Green
Black		1–30	0.5–20
White	0.5–30		1–50
Green	0.5–20	0.5–30	

Unit: kΩ

Alternator service

Remove the alternator cover and the components will be accessible for testing.



Field Coil Test (650)

Carbon brushes are marked with scribed lines. When wear reaches these lines, the brushes must be replaced.

Field coil resistance should be a few ohms.

Field Coil Test (Except 650)

Check continuity between the two field coil leads (white and green) using a multi-tester or a test light and the battery. If there is continuity, the field coil is satisfactory. Standard field coil resistance is 4.9 ohms, ± 10 percent. The field coil can be removed from the cover by simply taking out the three mounting screws under the plate on the outside of the cover.

Testing the field coil (1) leads with a multi-tester (2)

Stator Coil Test (All)

Check for continuity between the three stator coil leads (yellow) in the same manner as the field coil test. If there is continuity, the stator coil is satisfactory. Standard stator resistance is 0.61–0.69 ohm for the 350/400, 0.32–0.38 ohm for the 500/550 and 0.41–0.51 ohms for the 650. To remove the stator from the cover, simply take out the three mounting screws.

Testing the stator coil leads (1) with a multi-tester (2)

Rotor (All)

The alternator rotor need not be removed at this time. If it must be taken off, pull it off the crankshaft after the retaining bolt has been removed, using Honda tool number 07011–33301 (350/400) or 07933–2160000 (500/550) to avoid damage to the rotor or crankshaft taper. When reinstalling the rotor, tighten the retaining nut to 29 ft lbs (350/400) or 30 ft. lbs. (500/550), or 36–43 ft. lbs. (650).

BREAKER POINT IGNITION SYSTEM

The ignition system consists of the battery, breaker points, coils, condensers, spark plug caps, and spark plugs.

There are two sets of breaker points and two ignition coils. Each coil fires two cylinders. They are paired Nos. 1 and 4, and Nos. 2 and 3.

1. In the event of failure of the ignition system, first check the fuses, if all are in working order, check that the snap connectors for the coils and breaker points are all clean and tight.

2. If these items are all in working order, the problem may be isolated to the coils, condensers, or plug caps.

3. If only one cylinder fails to fire, and the problem is not a loose connection or defective spark plug, suspect the plug cap. The caps are fitted with a resistor to prevent radio interference while in operation, and heat and vibration may cause the value of this resistor to increase considerably, even to becoming an open circuit.

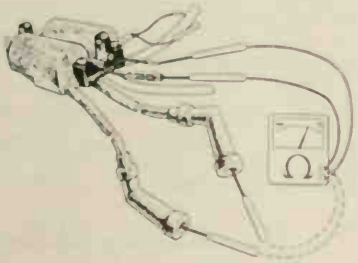
The easiest way to see if a misfire is due to a defective cap is to switch the plug lead of the non-firing cylinder with its corresponding cylinder (1–4, 2–3). If the dead cylinder begins to fire and the other cylinder ceases, the problem is the plug cap. The caps should be replaced as a set.

Functional caps will have a resistance of 5,000–7,500 ohms. Usually, when resistance reaches about 9,000 ohms, the plug for that cap will no longer fire.

Caps are easily removable by unscrewing them from their cables.

4. Defective condensers are seldom a problem, since these are now usually replaced along with the breaker points. Defective condensers will cause considerable arcing or sparking between the breaker point contacts while the machine is running, and this should be cause for replacement before they fail completely. Badly burned or pitted points contact surfaces can also be caused by defective condensers, as well as by improper adjustment. If the points are in bad condition, replace them and the condensers as well.

5. Condenser capacity can be checked with electrical test equipment (if available) in place on the machine provided that the condenser is first disconnected from the primary terminal. Capacitance should be 0.22 MFD (350/400) or 0.24 MFD (500/550). The resistance of the condensers should be in excess of 10 MΩ. A variation of 10% in either reading is allowable.



NOTE: *Be sure that the breaker points for the condenser being tested are open during the test.*

6. If the condensers are not suspect, check the ignition coils. Coils should be checked for continuity of the windings. First disconnect the blue and the black/white leads from the left coil and check for continuity between these leads. If there is none, the coil must be replaced.

For the other coil, carry out the same test between the yellow and the black/white leads.

Check for continuity on the high-tension side of each coil. Disconnect the two spark plug leads of one of the coils and check for continuity between them. If none exists, replace the coil. Repeat the test with the other coil. Remember you will be checking continuity between plug leads 1 and 4 and lead 2 and 3.

7. Coils are secured to the frame with two bolts and are easily removed if defective by disconnecting the wires, and removing the bolts after the gas tank is taken off.

Testing the ignition coil for continuity

TRANSISTOR IGNITION

Pulser Generator

Check the coil resistance after disconnecting the wiring coupler beneath the right side cover.

Resistance between the yellow and the yellow/white leads should be 530 plus or minus 50 ohms. This is for cylinder Nos. 2 & 3.

Resistance for cylinder Nos. 1 and 4 is checked between the blue and the blue/white leads. It should have the same value.

Spark Unit

Disconnect the wires at the pulser generator.

Attach the positive probe of a voltmeter to the blue/yellow terminal or the yellow/white terminal of the 6-prong connector. Ground the negative meter probe. Turn on the ignition switch.

Ground each terminal (blue/white or yellow/white of the 4-prong connector intermittently.

The voltage should change from 12 v to zero in each test.

The blue/white terminal is for cylinder Nos. 1 and 4. The yellow/white is for cylinder Nos. 2 and 3.

STARTING SYSTEM

The starting system consists of the starter motor and clutch, the solenoid, and the handlebar-mounted starter switch. When the button is pressed, the electrical circuit to the solenoid is closed and the solenoid is activated, sending the battery current directly to the starter motor. The starting system is quite reliable and it is unlikely that any major problems will arise.

Testing

The following two paragraphs are applicable to machines with a switch, a by-pass is incorporated to kill the headlight when the starter is used.

If the starter will not operate, switch on the headlight and observe its intensity. If it is dim when the starter is not being operated, check the battery connections and recharge the battery. If the headlight doesn't light, check the fuse, the battery connections, the ignition switch and its connections, and check the continuity of the wire between the ignition switch and the battery.

If the headlight is bright, press the starter button momentarily and watch the light. If it

...remains bright, touch a screwdriver blade between the two starter solenoid terminals. If the starter operates, connect a test light between the small yellow/red wire on the solenoid and ground. If the test light comes on as the button is pushed, the solenoid is faulty. If it does not light, look for defective wiring between the starter button and solenoid or between the starter button and ignition switch, or simply a burned out starter button switch. If the starter does not operate and the headlight dims as the main solenoid terminals are bridged, the starter motor is faulty. If the headlight does not dim, look for a bad connection at the starter.

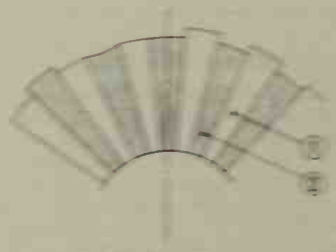
If the starter motor operates freely but will not turn the engine over, the starter clutch is not functioning (a rare occurrence). To remove the starter clutch it is necessary to remove the engine and split the cases. Refer to the section on transmission and primary drive service in chapter 4 for removal and installation procedures.

Starter Motor Service

REMOVAL AND INSTALLATION

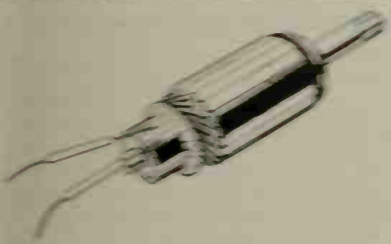
1. Disconnect the cable from the positive battery terminal.
2. Disconnect the starter motor cable from the solenoid.
3. Remove the starter motor cover and the left-side crankcase cover.
4. Unscrew the two starter motor mounting bolts and lift the starter out.
5. Installation is in reverse order of removal.

INSPECTION

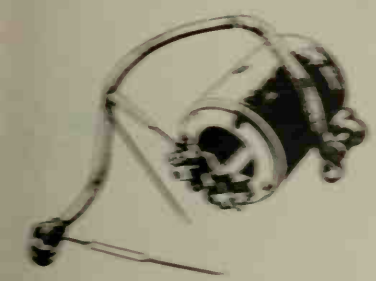


1. Take out the two screws and remove the starter cable cover.
2. Check electrical continuity between the commutator and armature core, using a multi-tester or test light and battery. If continuity exists, the armature coil is grounded and the armature or complete starter motor unit should be replaced.
3. Check for continuity between all of the commutator segments. Continuity must exist in each case.
4. Check continuity between the brush that is wired to the stator coil and the starter motor cable. Lack of continuity indicates an open circuit in the stator coil and the starter motor unit should be replaced.
5. Examine the carbon brushes for damage to the contact surfaces and measure their length. Replace the brushes as a set if either one measures less than 7.5 mm (0.30 in.), or if they are damaged in any way.
6. Brush spring tension should be measured with a small pull-scale. Replace the springs if they have weakened to less than 1.4 kg (3.1 lb) tension.
7. The outer undercut of the commutator should be maintained at 0.5 mm (0.02 in.). Any carbon deposits should be cleaned out of the commutator grooves, and a piece of hacksaw blade or the like used to increase the undercut depth if necessary. Refer to the illustration.

Brush (1) and brush mounting screw (2) location



Measuring brush (2) length with vernier calipers (1)

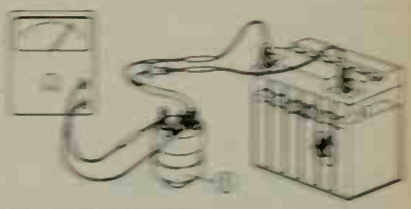


The mica (2) should undercut the commutator (1) by 0.8/32 in. (0.5 mm)

8. Polish the commutator with fine emery cloth and then clean it thoroughly before installing.

Checking for continuity between commutator segments

Testing the stator coil for continuity



Starter Solenoid

1. If the battery is in reasonably good condition, and nothing at all happens when the starter button is pushed, check the solenoid.
2. Disconnect the starter cable at the starter motor. When the button is pushed, there should be an audible "click" which indicates that the solenoid is operating.
3. If further testing is necessary, remove the solenoid from the machine.

CAUTION: Be sure to disconnect the cables at the battery before disconnecting the solenoid terminals.

Connect a fully charged 12-volt battery across the solenoid low-tension leads and check for continuity across the high-tension terminals with an ohmmeter or self-contained test light. If there is no continuity, replace or repair the solenoid.

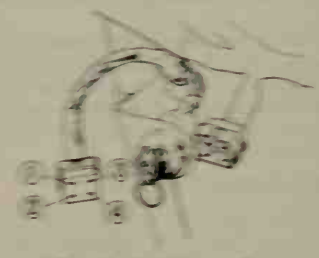
4. Check for continuity across the low-tension terminals with an ohmmeter or self-powered test light. If there is none, the primary winding of the solenoid is broken, and the unit must be replaced.

Testing the solenoid (1)

5. The primary cause of solenoid malfunction is pitting and/or burning of the contact points inside. It may be possible to restore a solenoid to serviceable condition by taking it apart and dressing the points with a file or emery paper. If this doesn't work, replace it.
6. If starter trouble began just after the starter button housing was disassembled, or moved for any reason, check the connections at the switch as they may have come adrift.

ELECTRICAL COMPONENTS

Turn Signal Flasher



If none of the turn signals will flash, chances are that the turn signal flasher has failed. A Signal-Stat 142 flasher is used on the Fours and is located near the battery.

NOTE: The flasher must be properly grounded to operate.

Switches

TESTING AND REPLACEMENT PROCEDURES

The operation of any switch can be checked using a multi-tester or test light to determine the electrical continuity of the switch in its different positions. Follow the procedures given below for testing the individual switches. If, during any test, you find that continuity is available at the switch but the switch won't work, make sure that it is not simply a bad ground that is salvaging it before you buy a replacement. Removal and installation procedures are given after the testing information, as it is not necessary to remove the switches in order to check them.

Main switch continuity test connections

IGNITION (MAIN) SWITCH

Pull the ignition switch connector apart and check continuity of the switch in its three positions using the accompanying chart as a guide. If any part of the test shows the switch to be faulty, the switch should be replaced.

The switch can be removed after the retaining nut has been unscrewed.

		BAT	IG	TL 1	TL 2
Wire Color		Red	Black	Brown/ White	Brown
Key position	OFF				
	1	○——	——○	○——	——○
	2	○——	——	——	——○

FRONT AND REAR BRAKE LIGHT SWITCHES

The front brake light switch is located between the fork legs just under the headlight. To check its operation, connect the two test leads to the switch terminals, leaving the switch wires connected, and operate the front brake lever. If the tester does not show continuity as the brake is applied (ignition on), check to see if there is electricity at the switch power supply lead (black wire). If there is, replace the brake light switch. If there is not, check the continuity of the black wire between its connections at the brake light switch and ignition switch to determine if there is a loose connector, a short circuit, or a break in the wire.

The front brake light switch can be removed by pulling off the wires and unscrewing it. It may be necessary to bleed the brake after installation.

The rear switch may be tested in the same manner as the front switch. Make sure that it is not simply improperly adjusted and that the spring is strong enough to actuate it. Adjustment can be made by turning the large nut on the switch.

HORN BUTTON AND HORN

If the horn is not working, check to see if it is receiving electricity by connecting the tester between the light green wire at the horn and a good ground (such as the engine crankcase). Turn on the ignition and press the horn button. If the tester responds, the horn is faulty or is not properly grounded. If the tester does not respond, connect the tester lead to the light green wire in the headlight shell and press the horn button again (ignition on). If there is still no electricity available, replace the horn button. If there is electricity at the headlight shell but not at the horn, check the green wire for loose connections or a short circuit between the headlight and horn.

NOTE: *Horn loudness can be increased by turning the adjusting screw in (clockwise). The horn button and turn signal switch are in the same switch case, which can be removed after the screws in the bottom half of the case are taken out.*

TURN SIGNAL SWITCH

To check operation of the turn signal switch, pull apart the connectors for the orange, gray, and blue wires in the headlight shell. Check continuity of the switch in its three positions with a multitester or test light and battery, using the accompanying chart as a guide. (Be sure to connect the tester to the three wire ends leading to the switch, not the turn signal bulbs.) If any part of the test shows the switch to be faulty, it should be replaced.

Knob	Blue Lead	Gray Lead	Orange Lead
R	○——	——○	
OFF (center)			
L		○——	——○

To remove the switch, take out the screws at the bottom of the switch case and separate the upper and lower halves of the switch.

LIGHTING SWITCH

To check operation of the lighting switch, pull apart the connectors for the black, blue, brown/white, and white leads in the headlight shell. Check continuity of the switch in its different positions, using the accompanying chart as a guide. (Be sure to connect the tester to the three wire ends leading to the switch, not the lights. The brown/white wire is for the highbeam indicator light.) If any part of the test shows the switch to be faulty, it should be replaced. The switch can be removed after the screws in the bottom half of the case have been taken out.

Wire Color		IG Black	HB Blue	TL Brown/ White	LB White
ON	H	○—	—○—	—○	
	P	○—	——	—○	
	L	○—	——	—○—	——○
OFF					

IGNITION KILL SWITCH

Check operation of the kill switch by pulling apart the connectors for the black and black/white wires in the headlight shell, and testing for continuity of the switch in both the "on" and "off" positions. Electrical continuity in either of the "off" positions, or *lack* of continuity in the "on" position, indicates a bad switch. (Be sure to connect the tester to the wire ends leading to the switch, and not to the ignition coil and ground.)

Ignition Kill Switch		
Wire Color	Black	Black/White
ON	○——	——○
OFF		

The switch can be removed after the screws in the bottom half of the case have been taken out.

STARTER BUTTON

Check operation of the starter button by connecting the tester between the yellow/red wire in the headlight shell and ground. Lack of continuity with the button depressed indicates a bad switch.

Starter Switch		
Wire Color	Ground	Yellow/Red
ON	○——	——○
OFF		

The switch can be removed after the screws in the bottom half of the case have been taken out.

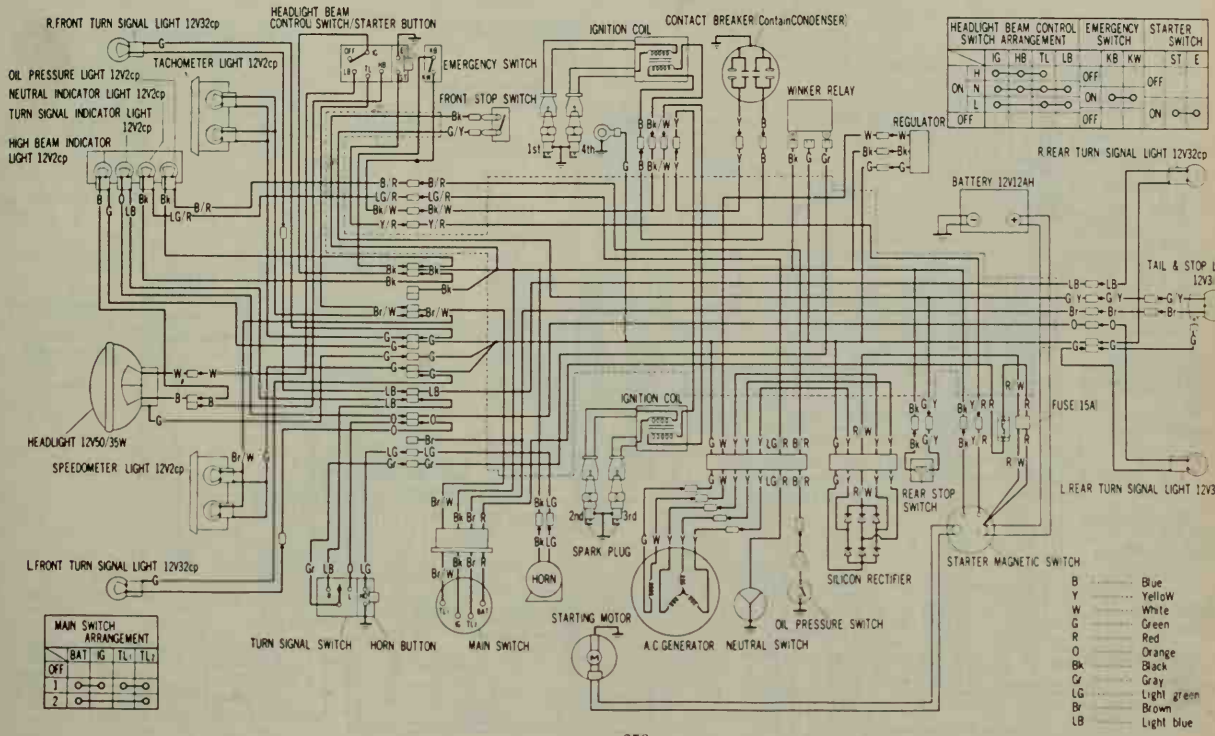
OIL PRESSURE SWITCH

When oil pressure drops below approximately 4.3 psi on the 350/400, or 7 psi on the 500/550, the oil pressure switch closes, completing the ground circuit of the oil pressure warning light which will then light up. There is no power supplied to the oil pressure switch and it must be tested using equipment with its own power source such as a multimeter or test light and battery. Connect the meter leads to the oil pressure switch lead and to ground. If the tester does not respond, the switch has not closed and is defective. (The engine must not be running or else oil pressure will be too high to allow the switch to close.)

Oil pressure control switch location

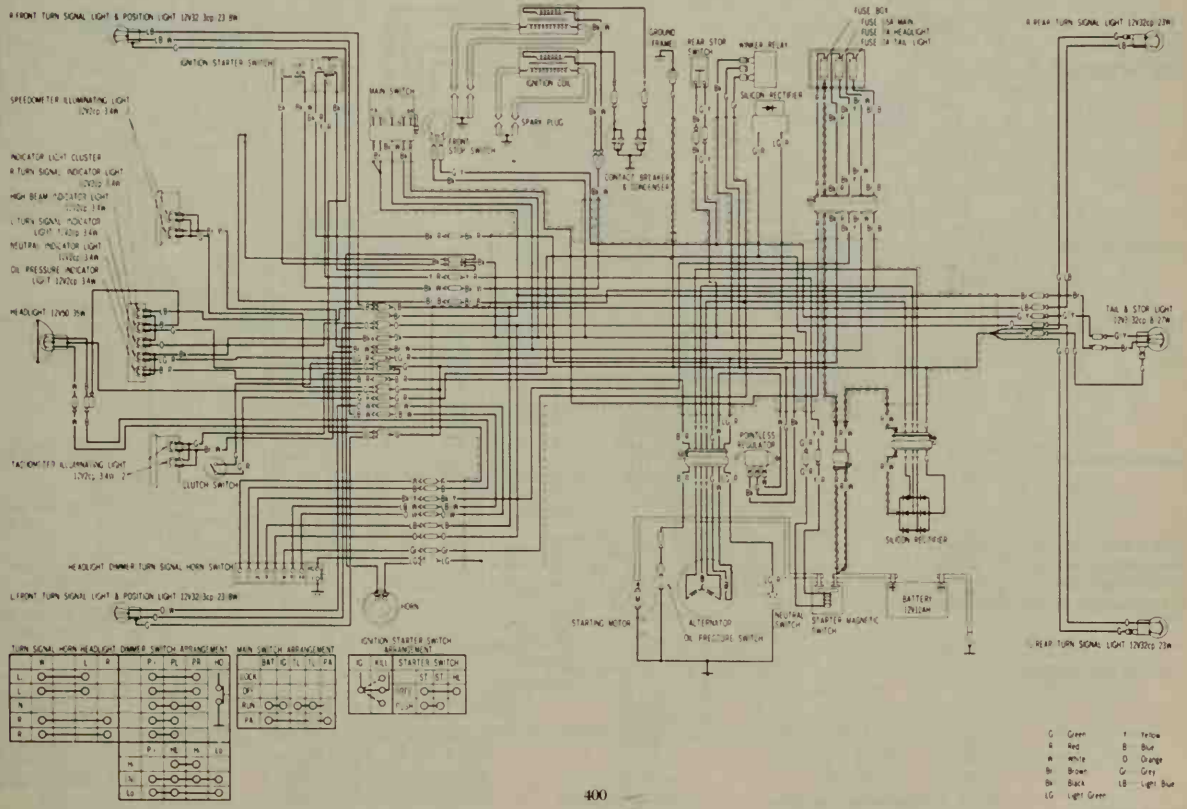
The oil pressure switch is located on top of the oil pump. To remove, simply unscrew the switch unit after the lead has been disconnected.

NEUTRAL INDICATOR SWITCH



In the same manner as the oil pressure switch, the neutral indicator switch closes and completes the ground circuit to the neutral indicator light when the transmission is placed in neutral, at which time the light should go on. If it refuses to do this, connect a tester with its own power supply to the switch (with the transmission in Neutral) means that the switch should be replaced.

The switch is located on the left-side of the upper crankcase.



Neutral indicator switch location

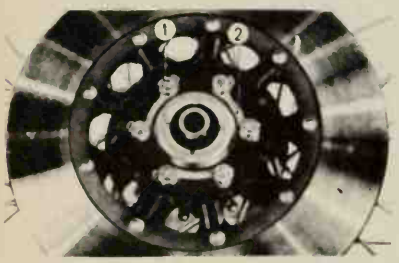
NOTE: *Refer to the General Information section for data on tires and wheels.*

WHEELS

Front Wheel Assembly

REMOVAL AND INSTALLATION

1. Raise the front wheel off the ground by placing a support under the engine.
2. Disconnect the speedometer cable from the front hub.
3. On dual-disc wheels, remove one of the brake calipers. Loosen the axle clamp bolts. Remove the axle nut and pull out the axle. On single-disc wheels, remove the four axle clamp nuts (two on each side) and withdraw the front wheel assembly from the forks.



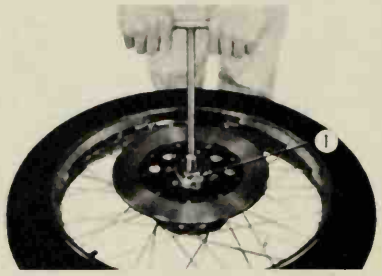
CAUTION: *Do not operate the front brake while the wheel is removed or the caliper piston will be forced out of the cylinder.*

Installation is in reverse order of removal. The front axle holder clamps are machined so that the forward mating surface is slightly higher than the rear mating surface and they must be installed correctly. Place a straightedge on the mating surfaces to determine which end is higher, and *install the high mating surface forward*. Tighten the forward retaining nut first, drawing the forward mating surface of the holder clamp flush against the fork leg mating surface and then tighten the rear nut.

WHEEL BEARINGS

Removal

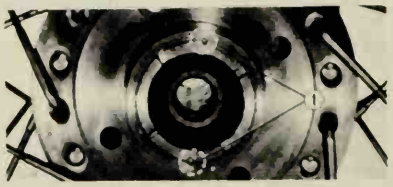
1. After removing the front wheel, unscrew the axle nut and withdraw the axle and axle collar.
2. Remove the screw and remove the speedometer gearbox from the hub.
3. Bend back the locktabs, and unbolt and remove the brake disc.
4. Remove the speedometer gearbox drive flange retainer and O-ring. Remove the drive flange.



Bend back the locktabs (2) and remove the nuts (1) to remove the disc

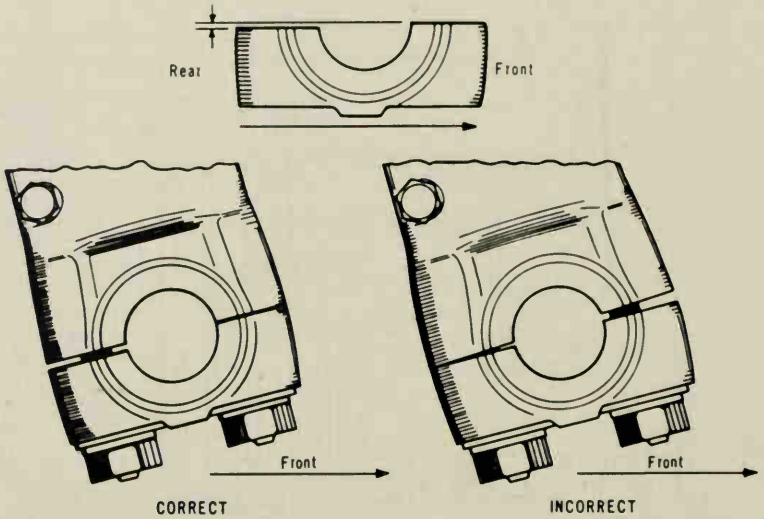
Using a bearing driver (1) to install a bearing

5. Unscrew the wheel bearing retainer from the other side of the hub. Withdraw the bearings and spacer.



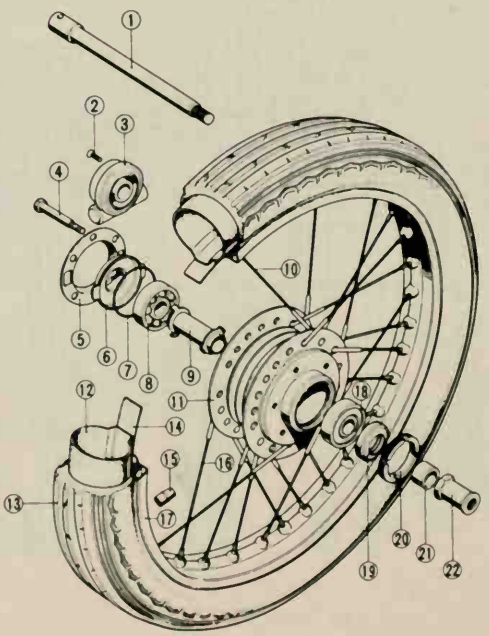
Removing the front wheel bearing retainer

Installation



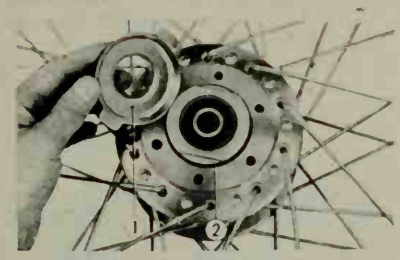
Assembly is the reverse of the above.

Note the following:

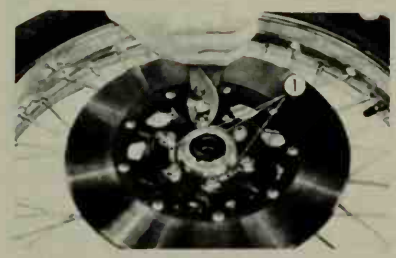


1. Pack the bearings with a good grade of wheel bearing grease. Put a small handful of the grease in the hub as well.

Stake (1) the bearing retainer in two places



Installation of axle caps



1. Axle
2. Screw
3. Speedometer drive
4. Bolt
5. Speedometer drive flange retainer
6. Speedometer drive flange
7. O-ring
8. Wheel bearing
9. Spacer

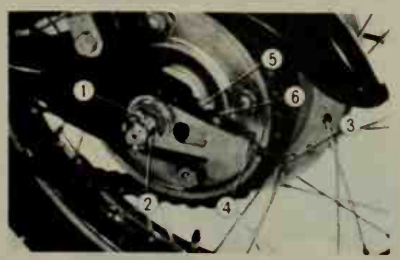
11. Hub
12. Tube
13. Tire
14. Tube protector band
15. Balance weight
16. Spoke
17. Rim
18. Wheel bearing
19. Oil seal
20. Wheel bearing retainer
21. Spacer
22. Axle nut

Front wheel assembly (500)

2. Do not forget to install the spacer in the hub before installing the bearing.
3. Bearings may be driven into place using the Honda service tool or a suitable substitute such as the front axle.
4. Use a new oil seal and lubricate it with oil to make installation into the bearing retainer easier.

Install the O-ring (2) before fitting the speedometer drive cover (1)

Bend up the locking tab of the tongued washers (1)



5. Stake the bearing retainer in two places after it is installed.
6. Do not forget to replace the O-ring behind the speedometer drive flange.
7. On dual-disc wheels, tighten the axle nut to 40–47 ft. lbs. Tighten the caliper mounting bolts to 22–29 ft. lbs.

Measure the gap between the left disc and the left caliper holder. It should be 0.7 mm/0.028 in. If it isn't, pull the left fork slider out until the gap is correct, then tighten the axle pinch bolt to 11–18 ft. lbs.

Rear Wheel Assembly

REMOVAL AND INSTALLATION

1. Place the machine on the center stand. On 350 and 500 models, remove the mufflers.
2. Remove the rear brake adjuster nut and separate the brake rod from the lever.
3. Disconnect the brake anchor from the hub by removing the lockpin and unscrewing the nut and bolt.
4. Loosen the chain adjuster bolt on both sides. Remove the cotter pin and loosen the axle nut.

Rear wheel axle mounting and chain adjusters (500)

1. Cotter pin
2. Axle nut
3. Adjuster bolt
4. Adjuster bolt locknut
5. Swing arm pinch-bolt
6. Stopper

5. Push the wheel forward and lift the chain off the rear sprocket.
6. Remove the lockbolts and chain adjuster stop plates. Withdraw the wheel rearward from the swing arm.

Installation is in reverse order of removal. Adjust the chain so that there is ½–¾ in. slack at the midpoint of the run. Brake pedal freeplay should be 1 in. (25 mm). Tighten the axle nut to 58–72 ft lbs.

WHEEL BEARINGS

Removal

1. After removing the rear wheel, remove the axle from the hub.
2. On 350/400 models, remove the hub circlip and tap the sprocket assembly out of the hub.

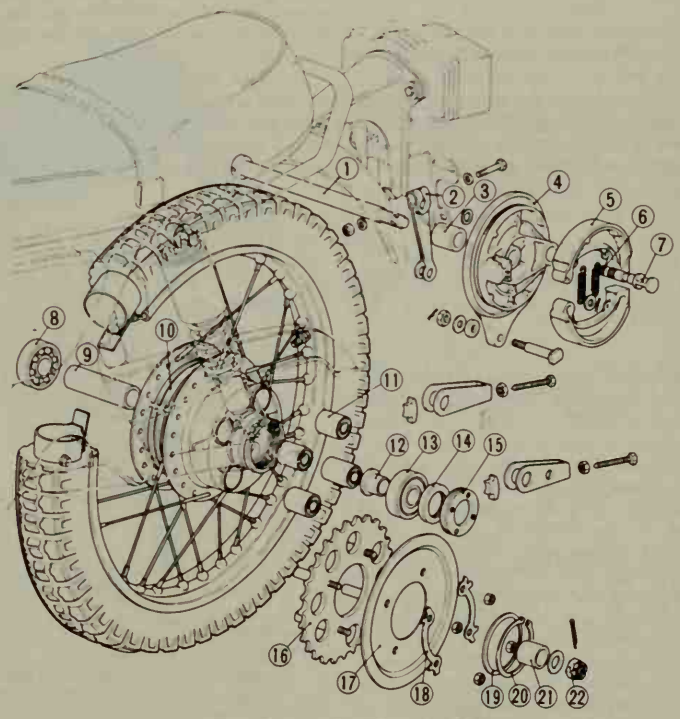
Removing the sprocket from the hub (350/400)

3. On 500/550 models, bend down the locktabs and remove the sprocket nuts to take off the sprocket.
4. On 650 models, loosen the sprocket nuts, remove the flange from the hub, and tap the assembly out of the hub.
5. Unscrew the bearing retainer and drive the bearings out of the hub.

NOTE: *On 500/550 models, the bearing retainer has a left-hand thread.*

Installation

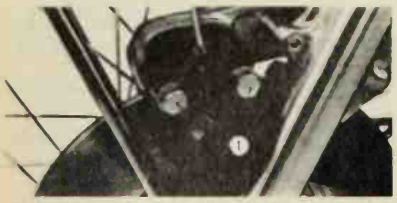
Reverse the removal procedure. Note the following:



1. Pack the bearings with wheel bearing grease. Place a small handful in the hub as well.
2. Do not forget the bearing spacer.
3. The bearings may be driven into place with the Honda tool or a suitable substitute.
4. Use a threat-locking compound on the bearing retainer.

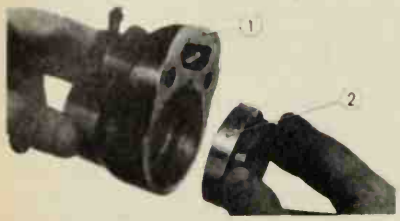
BRAKES

Front Disc (350–550)



PAD REPLACEMENT

1. Check the pads for wear by noting the red wear indicator line inscribed on them. Replace the pads as a set when either is worn close to this red line.
2. Remove the front wheel. Remove the two bolts from the side of the caliper and remove the right-side caliper half.



Rear wheel and brake assembly (350/400)

1. Rear axle
2. Brake arm
3. Collar
4. Brake backing plate
5. Brake shoe
6. Brake shoe spring
7. Brake cam
8. Wheel bearing
9. Spacer

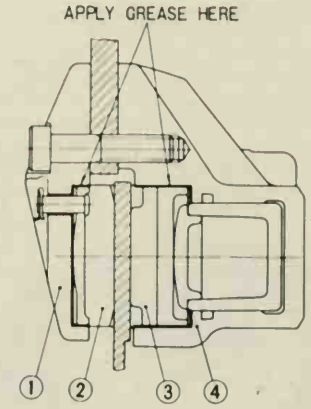
11. Damper
12. Spacer
13. Wheel bearing
14. Dust seal
15. Bearing retainer
16. Rear sprocket
17. Sprocket plate
18. Lockwasher
19. Washer
20. Circlip
21. Spacer
22. Axle nut

Remove the caliper bolts (1) to separate the caliper halves



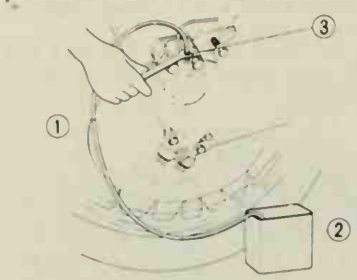
Removing the piston side pad (2) from the caliper half (1)

The cotter pin (3) holds the fixed pad (2) in the caliper half (1)

3. Remove the pad from the piston side of the caliper. Withdraw the cotter pin and remove the pad from the other caliper half.

4. Before installing the new pads, apply a small amount of silicone grease to the pad sliding surfaces on the caliper as shown. The grease serves to keep pad operation smooth by repelling dust and water as well as providing lubrication. Use grease sparingly and do not allow it to contact the pad friction material.

When fitting pads (2 and 3) into the caliper halves (1 and 4), lightly grease the assemblies as shown



5. Install the new pads in the caliper halves and bolt the caliper together.

6. Install the front wheel, and adjust the caliper as outlined in the "Maintenance" chapter. Avoid hard application of the brake for about fifty miles to aid seating of the pads.

BLEEDING

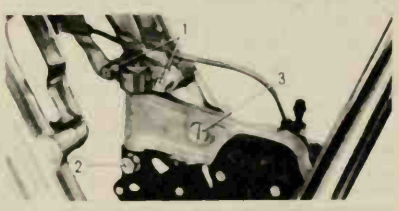
1. Top up the reservoir with brake fluid and replace the cap to keep dirt and moisture out and the fluid in. Cover the gas tank with a thick cloth to avoid damage due to spilled brake fluid.

2. Attach one end of a small diameter rubber hose to the bleed valve on the caliper, and place the other end in a jar which contains several inches of clean, new brake fluid. Be sure that the end of the hose is submerged in this fluid. Arrange the hose so that it loops upward after leaving the bleed valve, and see that it has no kinks or sharp bends.

Attach a bleeder hose (1) to the bleed valve (3), and run the hose into a container (2), immersing the hose end in clean brake fluid

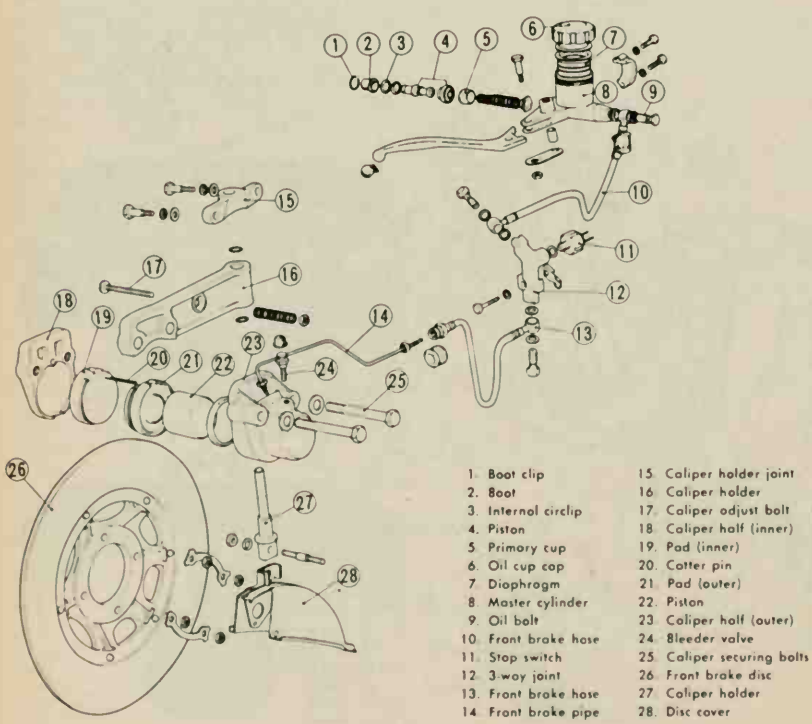
3. Pump the brake lever rapidly several times until some resistance is felt and, holding the lever against the resistance, open the bleed valve about one-half turn. When the lever bottoms, close the valve (do not overtighten) and then release the lever.

4. Repeat this operation until no more air is released out of the hose and the brake lever is firm in operation. Check the fluid level in the reservoir often to make sure that it doesn't go dry and draw more air into the system. Do not reuse fluid that has been pumped out of the system. Do not use fluid that has been stored for more than a few weeks after the seal on its container has been opened, as brake fluid will absorb moisture from the air and may corrode the master cylinder and caliper. Be sure to refill the reservoir to the level mark (do not overfill) when through. Avoid overtightening the cap or fluid will weep around the cap edge.



CALIPER

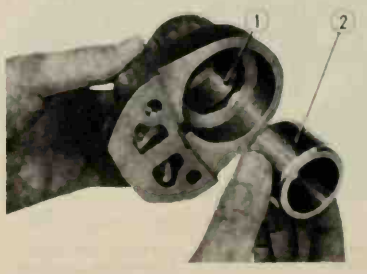
Leakage of brake fluid from around the caliper piston indicates that the caliper assembly is worn or damaged and the cause should be investigated immediately. To remove, inspect, and rebuild the caliper assembly:



1. Remove the front wheel.

2. Unscrew the hydraulic line connection at the caliper and catch the fluid that drains from the line in a suitable container and dispose of it. (Do not reuse old brake fluid.)

3. Unscrew the three caliper mounting



Caliper mounting bolts (1 and 2) and adjusting screw (3) locations

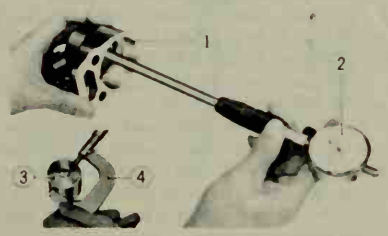
27. Caliper holder
28. Disc cover

Disc brake assembly



Removing the piston (2) from the caliper half (1)

bolts at the left fork leg and remove the caliper.

4. Remove the two bolts and separate the caliper halves.

5. Remove the pad seat from the caliper piston and withdraw the piston.

6. Remove the seal from the cylinder using a plastic or wood instrument to avoid damaging the bore.

Measuring the piston bore (1) and piston (3) with micrometer (2 and 4)

7. Examine the cylinder bore and piston surface for scoring and pitting, and replace if damaged. Cylinder bore diameter should not exceed 38.215 mm (1.504 in.) and piston diameter should not be less than 38.105 mm (1.500 in.). Maximum calculated clearance between the piston and cylinder is 0.115 mm (0.0045 in.). Replace parts as necessary. Clean all components and dry with compressed air.

8. Use a new seal in the cylinder bore and lubricate it thoroughly with fresh brake fluid before installing. Make sure that it is seated properly in its groove.

9. Lubricate the piston with brake fluid and install it in the cylinder. Be careful not to twist the seal or force it out of the groove. Install the pad seat on the piston.

10. Reinstall the brake pads in the caliper halves. Use new pads if the old ones have been in contact with brake fluid.

11. Bolt the caliper halves together and remount the caliper assembly on the fork leg.

12. Connect the hydraulic line and replace the front wheel.

13. Bleed and adjust the brake. Refer to the appropriate headings in this section.

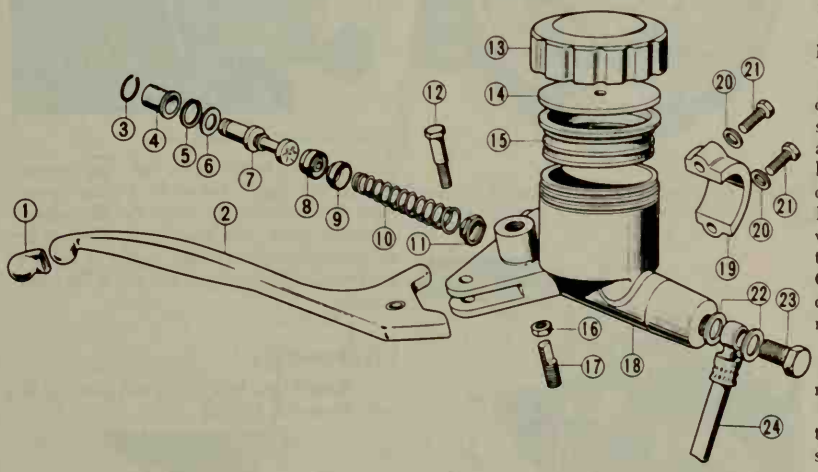
MASTER CYLINDER

Brake fluid leakage around the brake lever and excessive lever travel (after bleeding the brake to make sure that there is no air trapped in the hydraulic system) are indications of master cylinder malfunction. The rebuilding procedure is as follows.

NOTE: *Be very careful, when removing and replacing the master cylinder, in filling the reservoir. Brake fluid can damage paint and plastic, and extreme care should be exercised in its handling. Wipe up any spills immediately.*

1. Place a cloth underneath the connection to absorb any spilled fluid and disconnect the brake hose from the master cylinder.

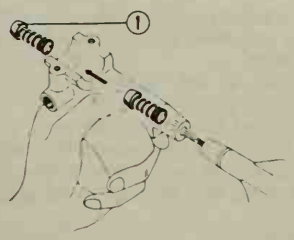
2. Unscrew the clamp bolts and remove the master cylinder from the handlebar. Unscrew the reservoir cap and discard the brake fluid.



3. Remove the rubber boot. Remove the snap-ring and withdraw the washer, piston, secondary cup, primary cup, spring and check valve.

4. Check the cylinder bore for scoring and pitting, and measure the wear using a dial indicator. Bore diameter should not exceed 14.055 mm (0.553 in.). Replace the master cylinder assembly if damaged or worn.

5. Clean all components in solvent and dry with compressed air.



Removing the snap-ring from the master cylinder (1) with snap-ring pliers (2)

20. Joint washers
21. Bolt
22. Brake hose

The primary cup (1) can be blown out with compressed air

Removing the check valve (1) and return spring (2)

Seating the primary cup (1) during assembly

6. Use a new seal and lubricate it with fresh brake fluid. Install the components in the bore as removed.

7. Mount the master cylinder on the handlebar and connect the brake hose. Do not forget to install the two washers at the connection.

8. Fill the reservoir to the level mark with brake fluid and bleed the brake. (Use brake fluid conforming to DOT 3 specification.)

Disc

The brake disc normally requires no service of any kind. However, if the disc becomes scored for any reason, it should be replaced and a new set of pads should be installed. A badly scored disc will reduce the effectiveness of the brake and shorten pad life considerably. If the front brake lever oscillates or fluctuates when the brake is applied at speed, the indication is that the brake disc is warped or bent. Check the run-out of the disc with a dial indicator and replace it if run-out exceeds 0.3 mm (0.012 in.). To replace the disc:

1. Remove the front wheel.

2. Bend back the locktabs, unscrew the six nuts, and remove the disc from the hub.

3. Mount the new disc on the hub and tighten the nuts evenly, using new locktabs to secure the nuts.

4. Examine the brake pads and replace them if they are close to the limit of wear or have worn in an unusual pattern.

Front Disc (CB650)

PAD REPLACEMENT

1. Remove the caliper cover. Take out the clip.

2. Push the caliper as far as possible towards the wheel and push the piston all the way in.

3. Remove the pins, brake pads, and shim.

4. When fitting new pads, apply a coat of silicon grease to both sides of the shim.

5. Install the new pads with the shim on the piston side of the pad. Fit the pins, clip, and cover.

BLEEDING

See "Bleeding," under "Front Disc (350-550)," above. Procedures are the same.

CALIPER

1. Taking care to avoid damage to painted surfaces, place a container beneath the caliper brake line banjo and remove the banjo bolt.

2. Loosen the two caliper shaft bolts gradually and evenly while pressing them in.

3. Remove the caliper from the fork slider.

4. Remove the piston boot.

5. Place a rag over the piston and hold the caliper with the piston facing down. Apply low-pressure compressed air to the banjo bolt fitting to push out the piston.

6. Pry out the fluid seal, taking extreme care not to scratch the caliper bore.

7. Clean all metal parts in clean brake fluid. All rubber parts should be replaced as a matter of course.

8. Check the outside surface of the piston for scratches or signs of wear and replace it if the piston surface is not perfect. Measure the OD of the piston. If it is under 42.800 mm (1.6850 in.) replace it.

9. Check the caliper bore for similar damage. Make sure that the fluid seal groove is perfectly clear of foreign matter. Measure the inside diameter of the caliper bore. If it is more than 42.940 mm (1.6905 in.), replace it.

10. Assembly is the reverse of disassembly. Use all new rubber parts. Be sure to lubricate the piston and seal with medium grade high temperature silicon grease or some new brake fluid before assembly.

Be sure that the fluid seal is firmly seated in its groove.

Be sure to install the piston with the boot lip facing out.

Tighten the caliper shaft bolts to 22–29 ft. lbs.

NOTE: *On some models the upper caliper bolt has a rubber seal and is marked for location.*

CALIPER CARRIER

The caliper carrier will remain on the fork slider when the caliper halves are removed. When rebuilding the system, remove the two carrier bolts and separate the components. Clean all metal parts in clean brake fluid. Replace the caliper shaft o-rings and boots. Lubricate the o-rings with silicon grease or new brake fluid before assembly. When assembling, be sure that the boots are seated in the caliper shaft grooves. Tighten the carrier bolts to 22–29 ft. lbs.

MASTER CYLINDER

The master cylinder components are the same as described for the "Front Disc (350-550)," above. Refer to that section.

DISC

Replace the disc if measured thickness is less than 6.0 mm (0.24 in.) at any point, or if the disc surface is warped, scored, or otherwise damaged.

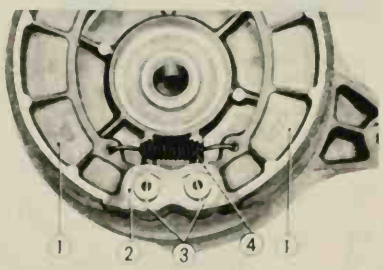
Rear Drum

Rear brake lining wear on newer models can be determined by means of the wear indicator pointer fitted to the brake lever on the hub. If the pointer lines up with the red slash mark when the brake pedal is fully depressed, the linings are worn beyond use and should be replaced.

On older models, observe the angle formed by the brake lever on the hub and the brake rod when the brake is fully applied. When the lever and rod form an angle greater than 90°, the shoes should be replaced. The replacement procedure is as follows:

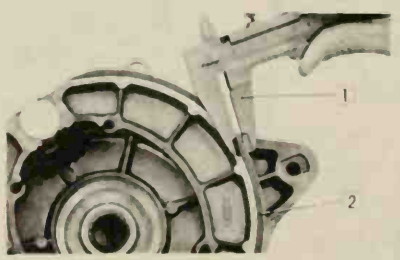
1. Remove the rear wheel.

2. Unscrew the axle nut and withdraw the axle. Separate the backing plate from the brake drum.



3. Remove the cotter pin and washer from each brake shoe pivot and lift the shoe away from the backing plate. Minimum acceptable lining thickness at any point is 2.0 mm (0.08 in.) for the 500/550/650 and for the 350/400 it is 2.5 mm (0.1 in.)

4. Check the linings for scoring or embedded foreign matter, and replace them if necessary. Oil or grease-impregnated linings should also be replaced.



5. Break the glaze on the linings with some medium sandpaper, but be sure to clean them thoroughly before installation.

6. Check the condition of the brake springs, and replace them if badly rusted or if the ends are deformed.

7. Apply a *light* coat of grease to the brake shoe pivots and the actuating cam. Install the springs and shoes as on removal, using new cotter pins.

Remove the cotter pins (3) and washers (2), then fold the shoes (1) off the backing plate and remove the springs (4)

Measuring shoe material (2) with a vernier caliper (1)

8. Inspect the condition of the brake drum surfaces. There should be no scoring. If scored, the drum can sometimes be salvaged by having it turned down on a lathe. Refer work of this nature to a qualified machinist.

9. Measure the inside diameter of the drum in two directions, perpendicular to each other. A difference in the two readings indicates that the drum is warped. This condition is sometimes felt in an "off-on-off" feeling when applying the rear brake, and it, too, may be remedied by turning down the drum.

Maximum allowable brake drum diameter is 161 mm (6.34 in.) for the 350/400 and 181 mm (7.13 in.) for the 500/550.

10. Clean the drum thoroughly, removing all dirt and dust.

11. Assemble the drum and hub with the axle and install the wheel. Adjust the brake so that there is about 25 mm (1 in.) of free-play at the pedal before the shoes contact the drum. Avoid heavy braking for a few miles if new shoes have been fitted.

FRONT FORKS (STANDARD)

Removal

1. Support the front wheel off the ground. Remove the front wheel and fender.

2. Remove the caliper from the fork slider.

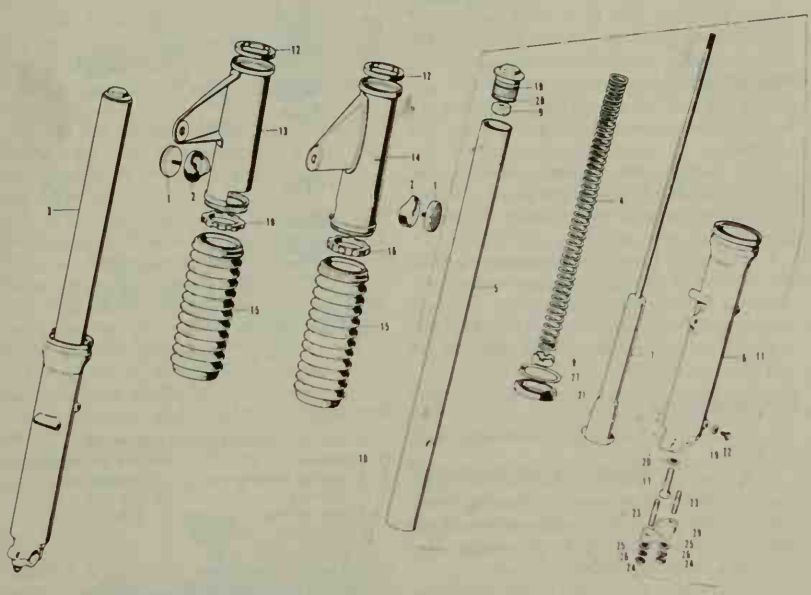
CAUTION: *Do not allow the caliper to hang by the brake hose. Tie it out of the way with string or wire.*

3. Remove the fork filler cap at the top of each fork leg.

NOTE: *It may be necessary to remove the handlebars to do so, but the controls may be left connected, and the bars gently laid to one side when the mounting bolts are removed.*

4. Loosen the upper and lower triple clamp pinch bolts.

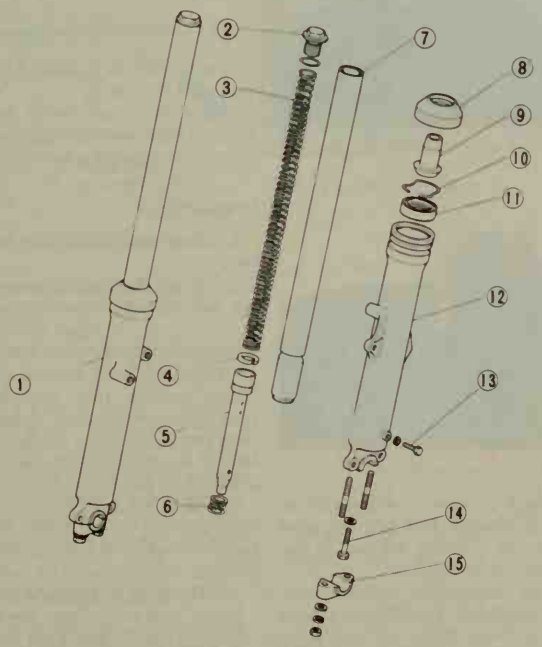
Upper and lower triple clamp bolts



5. Grasp each fork leg, in turn, and remove it from the triple clamps by pulling downward. If this is difficult, install the filler cap(s), threading them in several turns, then strike them sharply with a plastic mallet or the like to drive the fork leg down and out of the triple clamps.

Disassembly

1. Remove the fork spring and gaitor (if fitted). Drain the fork oil.



Removing the fork slider circlip

2. Filler cap
3. Fork spring
4. Piston ring
5. Damper
6. Rebound spring
7. Fork tube
8. Dust cap
9. Oil lock piece
10. Circlip
11. Oil seal
12. Fork slider
13. Drain plug
14. Allen bolt
15. Axle cap

2. Remove the fork slider dust seal, if fitted. Remove the slider oil seal circlip.

3. Remove the allen bolt at the bottom of the slider and separate the fork components.

4. The slider oil seal will remain in the slider. Oil seals must always be replaced when the forks are disassembled. Pry out the old seal with a screwdriver or a hooked tool, protecting the lip of the slider with a piece of

Removing the slider allen bolt

wood or soft metal pad beneath your lever. Drive new seals straight in until seated. An old seal can be used to drive in the new seals. Be sure the seals are driven straight in and not cocked or tilted. Seals should be driven in just far enough to allow fitting the circlip.

Oil the lips of seals before assembly.

Assembly

Assembly is the reverse of disassembly. On 400/550/650 forks, be sure that the rebound spring is in place.

Installation

1. Install each fork leg into the triple clamp and align the top of each fork tube with the surface of the upper triple clamp.

2. Tighten the upper triple clamp pinch bolts, the lower triple clamp bolts, and fill the forks with the correct grade and quantity of oil.

3. The remainder of the procedure is the reverse of removal.

AIR FORKS

WARNING: *1981 models are equipped with air forks. Special precautions are necessary when attempting to service these forks:*

1. Always wear hand and eye protection. Fork caps are under air and spring pressure.

2. Always depressurize the forks before attempting to disassemble them.

Removal

1. Depressurize the forks and disconnect the air hose from the right hose connector.

2. Disconnect the air hose from the left front fork.

3. Remove the front wheel, brake caliper(s), and front fender.

4. Loosen the triple clamp pinch bolts. Pull out each fork tube in turn.

Disassembly

CAUTION: *Fork caps are under spring pressure.*

1. Remove the air valve from the fork cap.

2. Install special plugs H/C 095806 and P/N M 2280-999-95806.

3. Secure the fork tube in a soft-faced vise and remove the fork cap remembering that it is under spring pressure.

4. Remove the fork spring.
5. Remove the dust seal, snap-ring, and back-up plate.
6. Remove the cap, tool, and seal. Pour off the fork fluid.
7. Extend the fork tube as far as possible. Pour ATF into the fork tube up to the bottom of the threads and install the fork tube cap.
8. Place the seal driver over the fork tube. Wrap a towel around the seal area.

Compress the fork tube slowly with a hydraulic press until the fork seal is forced out. Hold the driver against the seal during removal to keep it from tilting.

9. Remove the back-up ring with a magnet.
10. Remove the bolt at the bottom of the slider. Pull the slider and fork tube apart. It may be necessary to work the components apart due to the seal which is pressed into the slider.

Inspection

1. Replace the fork springs as a set if either measures less than 473.7 mm (1865 in.) on the CB650 or 542.7 mm (21.37 in.) on the CB650C.
2. Minimum acceptable fork tube diameter measured in the area on which the slider rides is 34.90 mm (1.374 in.).
3. Replace the bushing if the copper layer shows over more than ¾ of the total surface.

Assembly and Installation

Reverse the removal procedures. Note the following points.

a. Install the snap-ring with the radiused edge facing down.
b. Fork capacities are as follows:

CB650	210 cc (7.1 oz)
CB650C	245 cc (8.3 oz)

c. Torque the fork tube cap to 11–22 ft. lbs.
d. After the installation, fill each tube to 10–16 psi.

NOTE: *Use air only in the forks.*

STEERING STEM ASSEMBLY

Bearing Adjustment

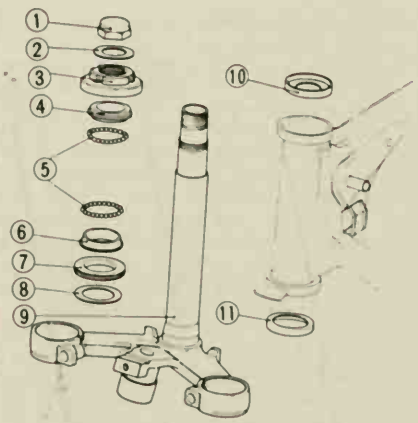
1. The steering stem bearings are uncaged #8 balls or ¼-in. balls. They are adjusted by means of a ring nut beneath the upper triple clamp.
2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender and place your other hand beneath the lower triple clamp at the frame lug.
3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn.

An alternate method is to grasp the fork sliders and attempt to move them back and forth in line with the motorcycle. No play should be noted.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.
5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The fork should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.
6. To adjust the bearings, remove the upper triple clamp. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.
7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above.
8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

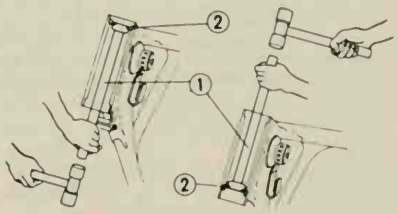
Disassembly

1. Remove the front wheel, front forks, and handlebars.
2. Loosen the rear pinch-bolt on the triple clamp, if fitted. Unscrew the steering stem nut and disconnect the speedometer and tachometer cables from their instruments. Remove the upper triple clamp.
3. Disconnect the wiring inside the headlight shell and remove the head-light shell and the fork ears.
4. Loosen the steering stem adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race and the ball bearings from the top race.



Removing the steering stem adjuster (2) with a hook wrench (1)

Top bearings (1) positioned on the race



5. Carefully pull the steering stem out from the bottom. Some of the ball bearings from the lower race will probably fall out at this time so be prepared for this.
6. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. These will have to be pried off with a chisel, therefore only remove them if necessary.
7. The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

Steering stem assembly

1. Steering stem top nut
2. Washer
3. Bearing adjusting nut
4. Top race
5. Ball bearings
6. Bottom race
7. Dust seal
8. Dust seal washer
9. Steering stem
10. Top race
11. Bottom race

New races are installed with a suitably sized bearing driver, i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

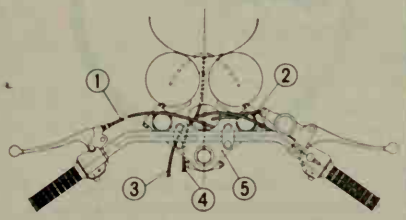
Using a drift (1) to drive out races (2)

These races can also be installed using a block of hard wood of sufficient size to cover the race in place of a bearing driver.

Inspection

1. Wash the ball bearings in a suitable solvent.
2. Clean all of the old grease from the bearing race surfaces, steering stem, and frame lug.
3. Inspect the bearing race surfaces. They must be clean and smooth and free of any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races. Note any roughness or ripples on the race surface. If any imperfections are noted, both sets of races and all of the balls must be replaced.
4. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

NOTE: *Balls and races must always be replaced in a set because worn races will destroy new balls and worn balls will destroy new races.*



5. Check the dust seal for condition and replace if torn or cracked.
6. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Installation

1. Install the dust seal washer, dust seal, and lower cone race on the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the upper race in the frame lug.
2. On the 350/400, install 19 balls in the upper race and 18 in the lower. On the 500/550/650, fit 18 balls into the upper race, and 19 in the lower.
3. When the balls are in place, slip the steering stem through the frame lug and hold it in place while refitting the top cone race and threading on the adjuster nut.
4. Tighten the adjuster nut all the way by hand, rotating the steering stem to work the grease into the balls.
5. Tighten the adjuster nut until the steering stem turns freely, but has no play.
6. Install the fork tubes, headlight assembly, and upper triple clamp, flat washer, and steering stem nut. Check that the stem moves freely to the steering lock of its own

Tightening down on the stem adjusting nut (2) while checking for smooth motion of the stem (1)

Correct routing for the cables and wiring

1. Clutch cable
2. Brake hose
3. Throttle cable
4. Wiring harness
5. Upper triple clamp

weight when released from 5°–10° off center; if not check for:

a. Steering bearings too tight;
b. Bent steering stem;
c. Worn races or balls.

7. Install the front fender, front wheel, and handlebars.

REAR SHOCKS

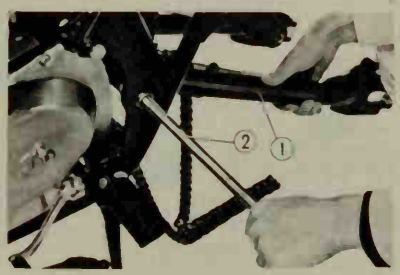
Rear shocks are sealed units which cannot be disassembled or repaired. If a shock is damaged due to accident or if it leaks oil, it must be replaced. Shock absorbers are best replaced in sets.

Removal and Installation

1. The shock absorbers can be removed after their upper and lower fasteners are taken off.
2. To remove the spring, first set the cam ring on the softest position. Then compress the spring by hand or with the aid of the special tool and remove the spring retainers.

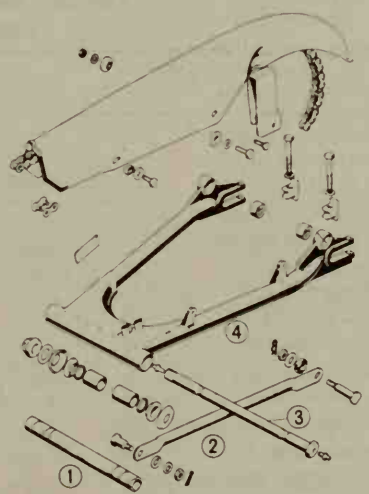
SWING ARM

Inspection



1. Remove the muffler(s).
2. Remove the rear wheel, shock absorbers, and chain guard.
3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.
4. Check that the rear wheel mounting plates are parallel.
5. Grasp the legs of the swing arm and attempt to move it from side to side. Any noticeable side-play will indicate that the swing arm bushings need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.



Removal and Installation

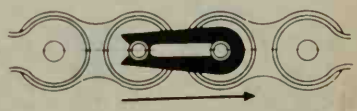
1. Proceed as above. Then remove the swing arm pivot bolt nut and pull the pivot bolt out from the right side.
2. Remove the swing arm by pulling it straight back.
3. The swing arm should be inspected for cracks or fractures, especially around the welds.

After removal of the swing arm, the dust seals and bushings can be replaced. This should be done every 10,000 miles or more often depending on how the machine is used, or if the bushings are worn (see "Inspection," above).

Removing the swing arm spindle (2)

Swing arm assembly (500/550)

1. Collar
2. Brake anchor
3. Spindle
4. Swing arm



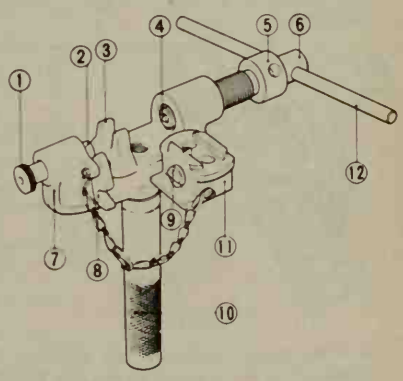
4. Remove the bushings, tapping them out with a hammer and punch. Once the bushings are removed, they should be replaced.
5. Lubricate new bushings with a good chassis grease. Press the bushings into the swing arm, then lubricate and install the swing arm collar.
6. Clean out the pivot bolt (500/550) and ensure that all grease passages are clear. Install the swing arm on the machine. Grease and install the pivot bolt. After tightening the swing arm pivot bolt nut, move the swing arm up and down to ensure that movement is smooth and effortless.

FINAL DRIVE

Chain Removal and Installation

MASTERLINK CHAINS

The chain can be separated and pulled off the sprockets after the master link has been removed. Threading the chain back onto the countershaft sprocket is made easier if you have an old length of chain lying around that you can hook onto the chain on the bike as it is removed. Leave the old chain draped over the sprocket so that you can hook the good chain back onto it and pull it over the sprocket when



Always install the spring clip with the closed end facing the direction of chain rotation

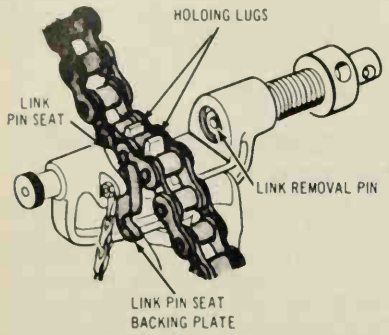
you are ready to reinstall it. Be sure to install the master link clip with the closed end facing in the direction of forward rotation of the chain.

ENDLESS CHAINS

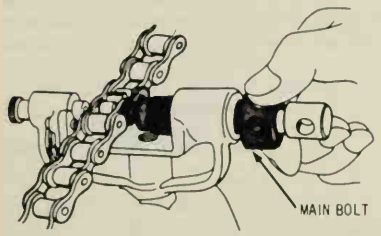
To remove the endless chain it is necessary to use a chain breaking tool. A heavy-duty chain breaker is available from Honda dealers, part number 07062–30050. To break the chain using this tool:

1. Grind or file the pins of the link to be removed flush with the link side plate. Break

Chain breaker



1. Pin seat knob
2. Pin seat
3. Holder
4. Cotter pin
5. Main bolt
6. Link removal bolt
7. Body
8. Pin seat backing plate
9. Wedge
10. Grip
11. Guide
12. Lever

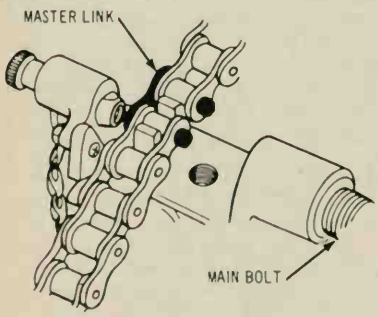


the chain at the master link (identifiable by the depression in the pin centers).

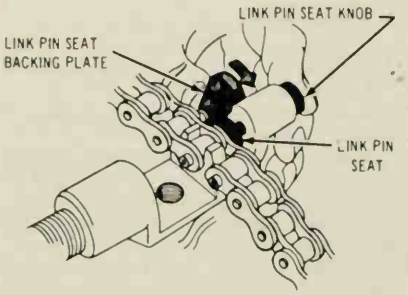
2. Swing the pin seat backing plate on the chain breaker away from the pin seat and place one of the link rollers in the holding lugs of the tool.

3. Seat the main bolt against the side plate of the link and turn the link removal bolt in until the pin is driven out.

4. Place the other link roller in the holding lugs and repeat step 3.



To install a new master link (replacing the chain on the motorcycle):

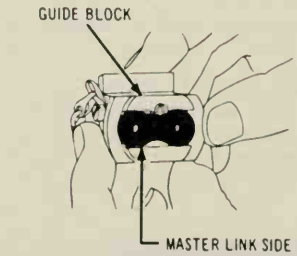


1. Insert the master link through the ends of the chain so that the side plate is inside (closest to the wheel).

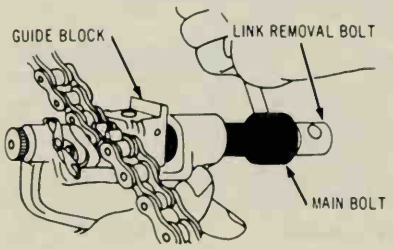
2. Place one of the master link rollers in the holding lugs of the tool with the pins facing the main bolt.

3. Push the pin seat knob in until it contacts the pin and swing the pin seat backing plate over to lock the pin seat in position.

4. Place the master link side plate in the guide block, as shown, so that the stamped



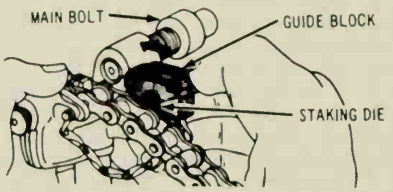
letters or numbers on the plate face the surface of the guide block (facing out when installed on the chain).



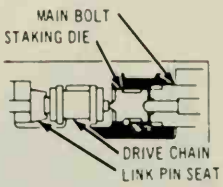
5. Back out the link removal bolt until it is behind the nose of the main bolt.

CAUTION: *The link removal bolt will be damaged if it is allowed to protrude beyond the nose of the main bolt.*

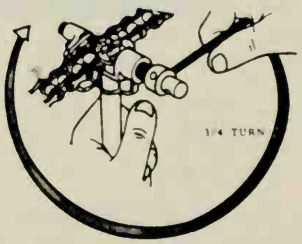
6. Place the guide block in the tool with the master link side plate against the pins. Make sure that the pins are aligned with the holes in the side plate.



7. Turn in the main bolt until the pins



pass through the plate and seat against the recess in the guide block.



8. Reposition the guide block so that the staking die faces the pin and the protruding shoulder of the guide block is below the side plate.

9. Turn in the main bolt until the staking die contacts the pin. Check to make sure that the die is centered across the pin.

10. Turn in the main bolt an additional ¾ turn to stake the pin. Repeat steps 8–10 for the other master link pin. Examine both pins to make sure that they are properly staked.

CAUTION: *The main bolt must be turned no more or no less than ¾ turn. Less than ¾ turn will not secure the side plate properly, and more than ¾ turn may crack the pin.*

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION

Engine

The crankshaft bearings, cylinder, and piston are lubricated by either Kawasaki Superlube or Injectolube.

The Superlube and Injectolube systems do not require maintenance except for a periodic check on the oil pump cable adjustment provided that the oil tank is kept full of oil. A level sight glass is provided for this purpose.

Any high-quality two-stroke oil recommended for air-cooled engines may be added to the oil tank. Each time you add oil, check that the oil tank breather hole is not clogged, or that the tank breather tube is not clogged or pinched at any point.

Transmission

The transmission and the clutch are lubricated by an oil bath. SAE 10W-30 or SAE 10W-40, service rating "SE" oil is recommended for all models.

CHECKING OIL

1. Set the motorcycle upright on a level surface so that it is perpendicular to the ground.

2. Start the engine and allow it to warm up for a few minutes, then shut it off, and give the oil about two minutes to settle in the crankcase.

Oil level dipstick (KS125 shown)

3. On some models a dipstick is incorporated into the filler cap. On these machines, remove the dipstick and wipe it clean. Insert the dipstick so that the filler cap rests on the top of the threads of its hole. Remove the dipstick and read the level. The level should be between the maximum and minimum marks on the dipstick.

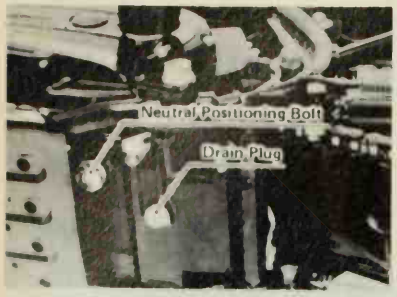
Oil level plug (MC1 shown)

4. On models without a dipstick there is an oil level plug in the right crankcase cover. With the motorcycle fully upright, oil should just seep out of the hole when the plug is removed.

5. If the oil level is low, add oil through the filler hole. Turn the ignition off and kick the engine over a few times to circulate the oil then recheck the level. Add oil until the level is up to the maximum mark on the dipstick or begins to seep out of the level plug hole.

CHANGING OIL

The transmission oil should be changed at least every 2,000 miles after break-in is over.



1. Oil should be changed when the engine is at or close to operating temperature.

2. The machine should be perpendicular to the ground, and on a level surface.

3. Remove the oil filler cap.

4. Remove the drain plug and allow the oil to drain off for several moments.

5. Check the condition of the drain plug gasket. Replace it with a new one if it is cracked or damaged. Refit the drain plug and tighten firmly.

Oil drain plug (F11 shown)

6. Fill the transmission with the correct type and quantity of oil. Capacities are given in the "Maintenance Data" chart at the end of this section. After filling, turn the ignition off, and crank the engine over a few times with the kickstarter. Allow a moment for the oil to distribute itself, then check the level with the dipstick or level plug.

NOTE: *The use of oil additives is not recommended, since they may cause clutch slippage.*

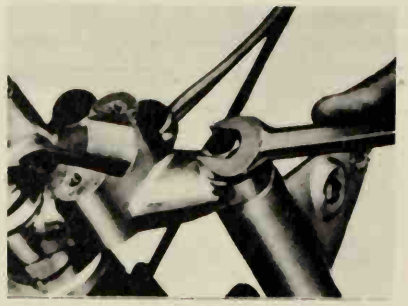
FRONT FORKS

F, M, AND KS SERIES

1. Fork oil should be changed every 4,000 miles. The specifications for the correct type and quantity of oil for each model are given in the charts at the end of this section.

Front fork drain screw location

2. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain into a suitable container; pump the slider up and down several times. (Sit on the machine after taking it off the center stand, apply the front brake, and push forward). After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit and tighten the drain plug.



3. Repeat the procedure with the other fork leg.

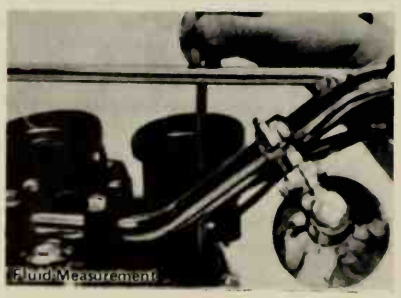
4. Remove the fork filler cap from the top of each fork leg after supporting the front wheel off the ground.

5. Add the correct quantity and viscosity of oil to each fork leg. Tighten the filler caps securely.

G SERIES

The forks on G Series models are not equipped with drain plugs. Therefore, the fork legs must be removed and inverted so that the oil can be drained from the top of the fork. Refer to "Chassis."

Removing fork filler cap



CHECKING FORK OIL LEVEL

1. Lift the front wheel off the ground so that the front forks are in the fully extended position. Remove the fork filler cap (on the KS125 just remove the screw from the center of the filler cap).

2. Insert a long rod into the fork tube and measure the distance from the top of the oil level to the top of the fork tube. The level of the KS125 fork is measured to the top of the filler cap. The correct specification for the level is given in the "Maintenance Data" chart at the end of this section.

3. If the level is low, add the same make and type of oil that is in use to bring the level to specifications.

4. If it is not possible to add the same make and type of oil, the oil should be changed.

Measuring the oil level in the front fork

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

2. Before checking or adjusting the chain the following conditions should be met.

a. The machine should be off the center stand, and with a rider sitting on the seat;

b. The chain should be cold, clean, and well-lubricated;

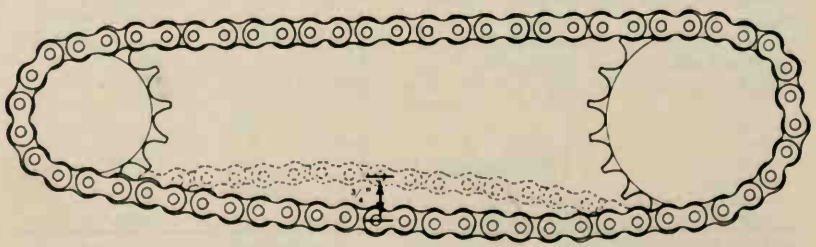
c. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain should be adjusted to the prescribed free-play at the tight spot.

3. To adjust the chain, first back off the rear brake adjuster nut if a rod-operated brake is fitted.

4. Remove the cotter pin from the brake anchor bolt, and loosen the brake anchor nut a few turns.

5. Remove the axle nut cotter pin and loosen the axle nut and sprocket nut (G-series), several turns. Loosen the locknut on each of the adjusters.

6. Turn each of the adjuster bolts in equal amounts until the chain tension is approximately correct.



NOTE: *The tension should be set by turning the adjusting bolts in. If the chain is too tight, back the adjustment bolts out several turns and kick the wheel forward in the swing arm. Turn the bolts in until the adjustment is correct.*

Wheel alignment marks

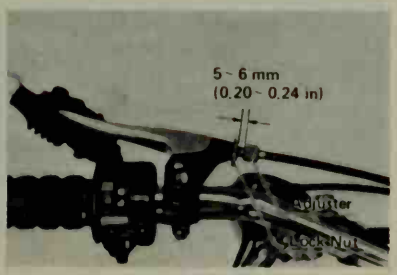
7. Check wheel alignment by means of the adjusting marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side.

8. Tighten the axle nut and check the chain tension. Correct if necessary. After adjustment is correct, tighten the axle nut and the sprocket nut (G-series), to the proper torque (refer to the "Chassis Torque Specifications" chart at the end of "Chassis." Fit a new cotter pin to the axle. Tighten the adjuster locknuts. Read-

Measure the drive chain free-play between the two sprockets on the lower chain run

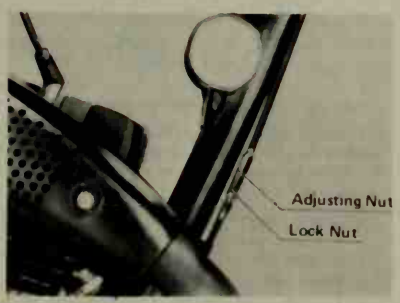
just the rear brake and check the operation of the brake light switch, and adjust it if necessary.

Clutch



Two adjustments are made to the clutch: cable adjustment and release mechanism adjustment. Usually, the release mechanism need not be adjusted unless the clutch malfunctions. Cable adjustment must always be maintained at the proper specification.

Clutch Adjustment



The following procedures are for the adjustment of both the cable free-play and the clutch release mechanism. Before attempting to adjust the clutch, ensure that the cable is clean and well-lubricated.

ALL MODELS EXCEPT F11

1. Slide the dust cover at the clutch lever housing (if fitted), back over the clutch lever.
2. Loosen the locknut on the adjuster at the lever housing, and turn the adjuster in or out so that there is 5–6 mm (0.20–0.24 in.), between the adjuster and the locknut when the locknut is tightened.

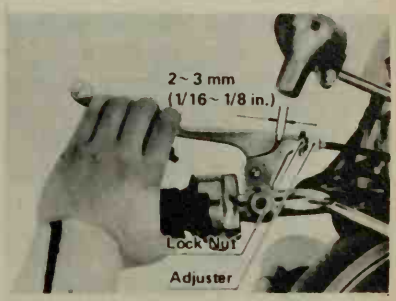
Set handlebar adjuster as shown before adjusting clutch pushrod

Cable adjuster in the middle of the clutch cable (KS125 shown)

3. Loosen the locknut on the cable adjuster in the middle of the cable. Turn the adjuster in so that the cable has a maximum amount of free-play.
4. On G and M Series models, remove the carburetor cover to expose the clutch release mechanism. On F6 and F7 models, remove the contact breaker cover. The F5 and F8 are equipped with a rubber access plug in the front chaincase cover. Once the cover is removed the pushrod adjuster is accessible.

Clutch release mechanism adjuster (KS125 shown)

5. Loosen the locknut on the release mechanism adjuster and back the adjuster out until it turns without resistance. It may not be necessary to turn the screw out if it already turns freely.
6. Using the cable adjuster in the middle of the cable, adjust the cable so that the projection on the clutch release lever is parallel to the mating surface between the left crankcase cover and the crankcase (KS125), or until the clutch release lever is at an 80° angle to the clutch cable.
7. Turn the release mechanism adjuster in until resistance is first felt. tighten the locknut. Do not turn the adjuster in past the point where resistance is first felt as clutch slippage will result. Replace the access cap or carburetor cover.



On KS125 models, the projection on the release lever must be parallel to the crankcase mating surface

Set the release lever to an 80° angle to the cable with the adjuster in the middle of the cable

8. Remove all of the free-play from the cable using the cable adjuster in the middle of the cable. Secure the adjuster with the locknut.
9. Screw in the adjuster at the hand lever so that there is 2–3 mm (0.062–0.125 in.), of free-play measured between the lever and the lever housing. Tighten the locknut and reposition the dust cover over the lever.

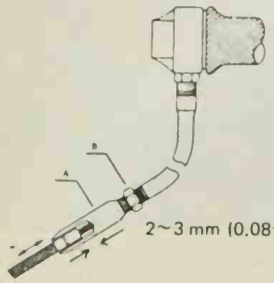
Final cable adjustment is made so that there is 2–3 mm of free-play measured between the lever and the lever housing

F11

1. Slide the dust cover at the clutch lever housing back over the clutch lever. Loosen the locknut on the adjuster at the lever housing, and screw the adjuster all the way into the lever housing.
2. Loosen the locknut on the cable adjuster at the engine side of the cable, and screw the adjuster in to give the maximum amount of free-play.
3. Remove the rubber access cap from the front chaincase cover to expose the release mechanism adjuster.
4. Loosen the locknut on the release mechanism adjuster, and screw the adjuster out until it turns without resistance.

Clutch adjuster (F11)

5. Turn the adjusting screw in until resistance is met, from this point back the adjusting out ½ turn and tighten the locknut.
6. Using the cable adjuster at the engine case, adjust the cable until only $^{1}/_{16}$–$^{1}/_{8}$ in. of free-play remains in the cable. This free-play is measured between the clutch lever and the lever housing.
7. Fine adjustment is accomplished with the adjuster at the lever housing. Also use this adjuster to maintain the free-play at the standard specification.



Throttle Control Cable

The throttle control cable is a three-part cable. The twist-grip cable runs from the twist-grip to a junction box where it connects with the throttle cable and the oil pump cable. In order for the oil pump to meter the correct amount of oil to the engine, all three cables must be correctly adjusted, in the proper order.

TWIST-GRIP CABLE

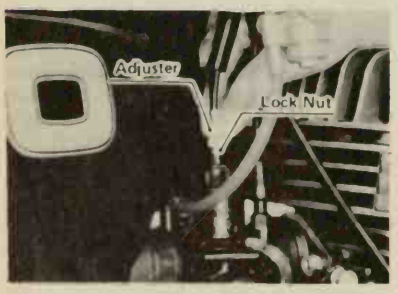
1. The twist-grip cable should be ad-

justed before the throttle cable or the oil pump cable.

The twist-grip cable should have 2–3 mm of free-play, measured by pulling on the cable sheath

2. Use the cable adjuster located near the twist-grip to effect the adjustment. The cable should have 2–3 mm (1/16–1/8 in.), of free-play. This can be measured by pulling on the cable sheath. The amount that the sheath can be moved is a direct indication of the free-play of the cable.

3. After adjusting the twist-grip cable, the throttle cable and the oil pump cable should be adjusted. This is especially important if additional slack was adjusted into the cable.



THROTTLE CABLE

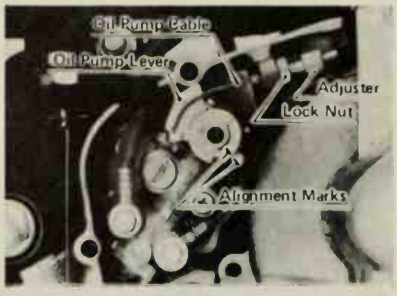
1. The throttle cable runs from the junction box where it is connected to the twist-grip cable to the carburetor.

2. To adjust the cable, first back the idle adjusting screw (throttle stop screw), out so that the throttle slide rests in the bottom of the carburetor bore. With the slide in this position the throttle cable should be adjusted to have zero free-play.

Throttle cable adjuster (rotary valve models)

Throttle cable adjuster (F11)

3. Use the cable adjuster located at the carburetor end of the cable to effect adjustment. On rotary valve models, it will be necessary to slide the rubber carburetor cap up on the cables to reach the adjuster.



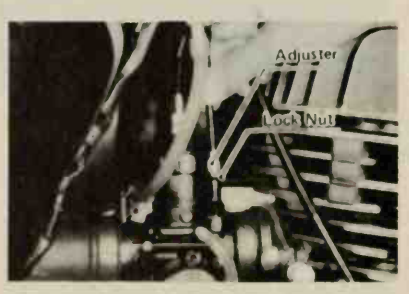
4. Loosen the locknut and screw the adjuster out so that any movement of the cable sheath will raise the throttle slide. Be sure that the cable is not adjusted so tightly that it is holding the slide up. Tighten the locknut. Adjust the idle speed. Refer to "Tune-Up."

NOTE: *When the idle speed adjustment is carried out a small amount of free-play will be adjusted into the throttle cable. This is normal free-play and SHOULD NOT be adjusted out.*

OIL PUMP CABLE

1. The oil pump cable should be adjusted after the twist-grip and the throttle cables.

2. Remove the oil pump cover from F11 and M Series models. On other F Series and G Series models, remove the carburetor cover. On the KS125, remove the front chaincase cover and the oil pump cover.



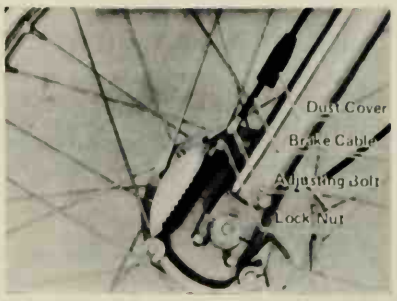
When the oil pump cable is correctly adjusted the marks will align at zero throttle opening (MC1 shown)

3. The oil pump cable is correctly adjusted if the aligning marks on the oil pump lever and the pump housing align at zero throttle opening.

4. If adjustment is necessary, loosen the locknut on the oil pump cable adjuster and turn the adjuster in or out until the marks on the oil pump lever and the pump housing align.

Starter Cable

1. The free-play of the starter cable can either be adjusted with the adjuster at the twist-grip or the adjuster at the carburetor.



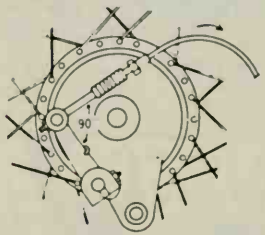
Starter cable adjuster (F11 shown)

2. Loosen the locknut on the adjuster and turn the adjuster until the cable sheath can be moved 2–3 mm (1/16–1/8 in.). Tighten the locknut.

Brakes

FRONT BRAKE

1. Use the cable adjuster on the brake plate to allow about 1/4 in. (6 mm), of brake handlebar lever free-play before the shoes contact the drum. This free-play is to be measured between the lever and the lever holder.



Adjust the front brake cable free-play with the adjuster on the brake plate

2. This free-play can be maintained as the shoes wear by using the adjuster at the handlebar lever.

REAR BRAKE

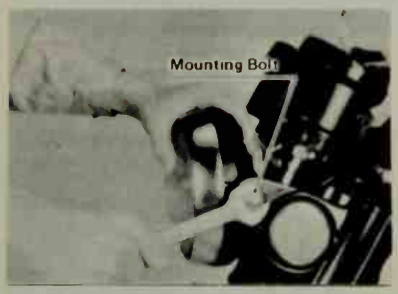
Use the adjusting nut on the end of the cable or rod so that the brake pedal has 1 in. of free-play before the linings contact the drum

NOTE: *If the angle between the brake cable or rod and the lever on the brake plate exceeds 90° when the brake is applied with all adjustment taken up, the lining thickness should be checked.*

The lining should contact the drum when the brake lever and the cable (or rod) form an angle of 90° or less for maximum brake effectiveness

BRAKE LIGHT SWITCH

The switch should be checked for operation after the brake is adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the light switch up on the bracket allows the brake light to turn on sooner. Moving it down allows it to come on later. Generally, the brake light should come on just as the linings contact the drum.

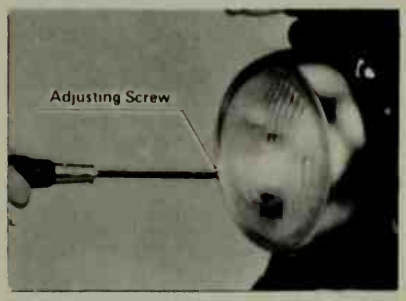


Steering Stem Bearings

The steering stem bearings should be checked periodically and adjusted if necessary. Refer to the "Chassis" section.

Headlight Adjustment

Set the machine about 25 feet away



from and perpendicular to a wall, preferably of a color which reflects light well. The machine should be off the stand, and with a rider putting his weight on the machine as in operation. Start the engine and switch on the high beam. The headlight high beam should be parallel to the ground, and should hit the wall directly in front of the machine.

Loosen the headlight mounting bolt for vertical beam adjustment

Vertical adjustment is made by loosening the two headlight mounting bolts slightly and pivoting the headlight up or down.

Lateral adjustment is made by means of the screw on the side of the headlight.

Lateral beam adjusting screw

FUEL SYSTEM

1. Fuel system maintenance involves cleaning the petcock and filter, cleaning or replacing the air cleaner, and cleaning the carburetor.

2. The carburetor should be removed, disassembled, and cleaned every 4,000 miles. The procedures are outlined in the "Fuel Systems" section.

3. The petcock should be serviced every 2,000 miles. Shut the fuel off, then unscrew and remove the petcock sediment bowl. Take out the fuel filter. Clean the parts in a solvent and reinstall. Check for leaks. Refer to "Fuel Systems" if necessary.

4. The air cleaner should be serviced or replaced every 2–3,000 miles, depending on conditions. If the air cleaner is the paper type, it should be kept free of water, solvents, etc.

The paper filters can be cleaned, after a fashion, by tapping off heavy dirt deposits, or brushing off the outside, and blowing compressed air through the inside of the filter element. These techniques, however, are limited in usefulness, and it is really preferable to replace the element every 5,000 miles or so (once again, depending on conditions).

Where filters are a tight fit in their housings, some liquid detergent or a bit of oil can be applied to the end plates to facilitate installation.

If a foam-type cleaner is used, wash it in gasoline to remove dirt, and squeeze until it is dry. Immerse the filter in a gasoline and oil mixture (20:1), and squeeze off the excess mixture. Then install the filter on the machine. Add additional gas/oil mixture to the filter whenever it dries out.

Maintenance Data

Model	Fuel Tank Capacity (gal)	Oil Tank Capacity (qt)	Transmission Oil Capacity (qt)	Fork Oil① Capacity (cc/oz)	Fork Oil Level① (mm)	Tire Pressure (psi) Front/Rear

① Each leg

Periodic Maintenance①

Daily (before each ride)
- Check lighting equipment and horn operation
- Check operation and adjustment of the brakes
- Tire condition
- Chain tension
- Cable adjustments
- Oil injection tank level

Weekly
- Transmission oil level
- Tire pressure (cold)
- Spoke tension
- Battery electrolyte level
- Chain condition
- Critical nuts and bolts

Monthly
- Trickle charge stored battery

Every 200 miles
- Lubricate chain

Every 2000 miles
- Change transmission oil
- Remove, clean and lubricate chain
- Lubricate control and instrument cables
- Check oil pump adjustment
- Clean fuel petcock
- Clean and gap spark plug
- Clean points and check timing
- Clean or replace air filter
- Adjust brakes
- Decarbonize engine and exhaust system

Every 4000 miles
- Change fork oil
- Pack wheel and steering head bearings
- Check brake linings
- Check sprocket condition
- Grease speedometer drive mechanism
- Clean carburetor
- Replace spark plug

① Based on normal usage after break-in is complete.

Recommended Lubricants

Oil Tank
- Any high-quality two-stroke oil recommended for air-cooled engines

Transmission
- SAE 10W—30
- SAE 10W—40

Forks
- SAE 10
- SAE 20
- SAE 5W

Drive Chain
- Any high-quality chain lube specifically developed for motorcycle drive chains

Wheel and Steering Head Bearings
- Lithium or moly-based grease

Cables
- Light motor oil
- Graphite-based lubricant
- Molybdenum disulphide-based lubricant

Grease Fittings
- Chassis grease

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information."*

For all breaker point models, a dial gauge should be used to set the ignition timing since this is the most accurate method. Timing marks are provided on the flywheel and the left crankcase. Although these marks can be used to set the timing with satisfactory results, this method is not as accurate as when the timing is set with a dial gauge.

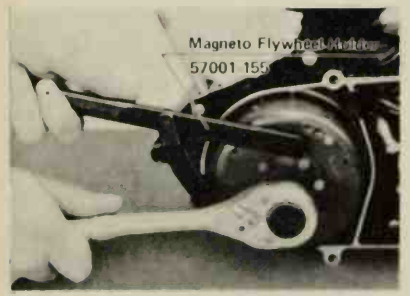
On all except CDI models, a device is needed to determine the instant the breaker points open (this is when the plug fires). For this purpose an ohmmeter or a point checker can be used.

To check the timing on models equipped with CDI, a stroboscopic timing light must be used.

Replacement of the breaker points necessitates removing the magneto rotor. A special puller is needed for this and is a must for getting the rotor off.

CONTACT BREAKER POINTS

Location



On all models (except those with CDI), the breaker points are located on the left-side of the crankshaft and operated off a cam in the inside of the flywheel. Remove the left crankcase cover to gain access to the points. Cutouts are provided in the flywheel to allow the points to be cleaned and the timing set.

Replacement

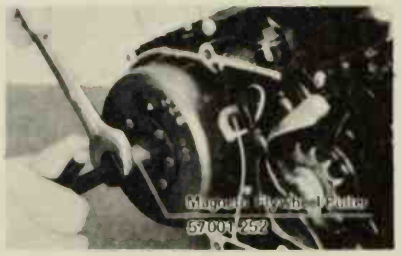
Two special tools are needed to replace the contact breaker points. A rotor holder is used to hold the magneto rotor from turning while the nut is removed, and a special puller is used to pull the rotor off its tapered shaft.

CAUTION: *The rotor puller is essential for this job. It is not wise to attempt to remove the rotor in any other way.*

1. Remove the left front crankcase cover, to expose the magneto flywheel. On KS-series models, the left rear cover must be removed first. On M-series models where the shift lever must be removed, first mark the lever and the shift shaft with a center punch so that the lever can be installed in the original position. The use of an impact driver to remove and install phillips head screws is recommended.

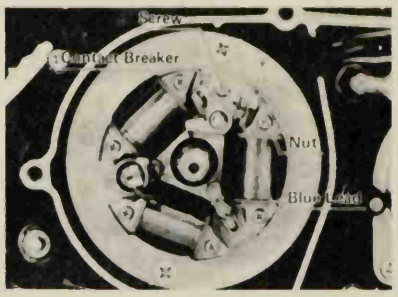
Removing the rotor nut while holding the rotor with the factory tool (KS125 shown)

2. Holding the magneto rotor with the special tool, or a suitable substitute, loosen and remove the rotor nut.



NOTE: *Alternately, engage the transmission and apply the rear brake to hold the rotor if a shop holder is not available.*

3. Thread the rotor puller into the rotor. The puller bolt should be backed off enough so that the puller outer has a good number of threads in the rotor.



NOTE: *The puller outer has a lefthand thread. Thread it into the rotor in a counterclockwise direction.*

4. Tighten the puller bolt against the end of the crankshaft to remove the rotor. The rotor should come off the taper. If it is stuck, tighten the puller bolt as much as possible and give it a sharp rap with a hammer. This should free the rotor. Note the key fitted to the crankshaft.

CAUTION: *Never use heat in an attempt to remove the rotor, since this may affect its magnetic properties.*

Using a flywheel puller to remove the flywheel (KS125 shown)

Disconnect the primary wire from the points, remove the securing screw, and remove the points

Handle the rotor with care: avoid dropping or striking it, as this, too, will affect its magnetism.

5. Disconnect the primary wire from the breaker point terminal. Note the way in which the primary wire is routed so that it will not be disturbed when the new points are installed. Remove the screw which secures the points to the stator plate. Remove the old points set.

6. Clean the contact surfaces of the new set of points to remove any protective coating present. Install the points and reconnect the primary wire.

7. Grease or oil the crankshaft taper slightly before fitting the rotor to make removal easier next time. Line up the slot in the rotor with the key in the crankshaft. Push the rotor into place. If the puller is still fitted back off the puller bolt, and strike the puller bolt once or twice to ensure that the rotor is firmly seated, but do not strike the rotor itself. Refit the rotor nut and tighten it securely. Reset the ignition timing.

Lubrication

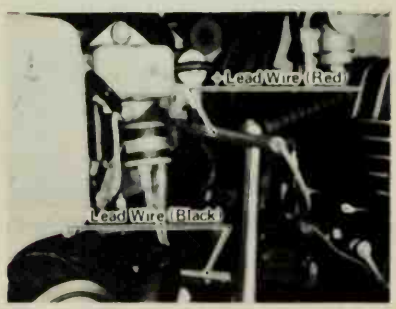
1. Whenever the points are replaced or the flywheel is removed, it is necessary to lubricate the cam follower fiber heel and the pivot point of the contact breaker.

2. A small dab of grease (high melting point, if possible) or oil should be applied to the lubricator felt so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.

3. In both cases it is imperative that care be taken to keep the lubricant away from the points.

4. The lubricating felt should be adjusted so that it just contacts the breaker cam.

5. If the felt is missing, or the model not equipped with it, the grease can be sparingly applied to the cam itself.



IGNITION TIMING

NOTE: *Points must be cleaned before attempting to adjust the timing. Dirty points will give inaccurate results.*

Breaker Point Ignition

TIMING WITH DIAL GAUGE

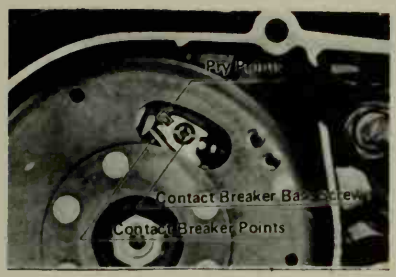
1. Remove the left crankcase cover to expose the magneto flywheel.

On F11 models, connect the positive lead of the ohmmeter to the black lead of the red connector and the negative lead to any ground such as the frame

2. Remove the cylinder head and the head gasket. Install the dial gauge to the top of the cylinder.

3. Attach the negative lead of the ohmmeter to a ground such as the engine case or any unpainted surface of the frame. Attach the positive lead to the points' primary wire.

4. Slowly rotate the engine until the gauge indicates its highest reading and begins to reverse. The highest reading is top dead center (TDC). Turn the engine a few degrees in either direction to recheck your finding, then position the piston at TDC and zero the gauge.



5. Turn the engine backward (rotate the rotor clockwise), to a position about 3–4 mm (0.11–0.15 in.) BTDC as indicated by the dial gauge. Since most models fire about 2 mm BTDC, the points will be closed at this point. (Zero resistance on the meter).

6. Slowly turn the engine in the normal direction of rotation (counterclockwise), until the dial gauge indicates that the piston is at the firing point. This point is given for each model in the "Tune-Up Specifications" chart at the end of this section.

7. When the piston reaches this point, the points should open (as indicated by the reaction of the meter), if the ignition is correctly timed. If the points open before the correct position, the timing is too far advanced. If they open when the piston is past it, the timing is retarded.

8. If adjustment is necessary, loosen the screw which secures the contact breaker points to the stator plate. This screw is accessible through a window in the flywheel. If the timing was advanced, decrease the point gap. If the timing was retarded increase the point gap.

9. Repeat the procedure until the points open at the instant the piston reaches the correct distance BTDC.

Use a screwdriver in the pry points to effect timing adjustment (KS125)

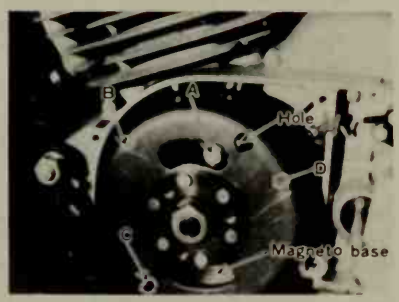
TIMING WITH TIMING MARKS

1. Remove the left crankcase cover to expose the magneto flywheel.
2. Attach the negative lead of the ohmmeter or the points checker to a ground such as the engine case or any unpainted surface on the frame. Attach the positive lead to the points' primary wire.

Timing marks—KS125

Timing marks—MC1

3. Marks are provided on the flywheel and the left crankcase to set the timing. If there are two marks on the flywheel, the one on the left is to be used as the timing mark. When the marks on the flywheel and the crankcase are aligned, the piston is in the correct position (firing point), to set the timing.
4. Slowly turn the engine in the normal direction of rotation (counterclockwise), until the timing marks on the flywheel and the crankcase are aligned.
5. When the timing marks align, the points should open (as indicated by the reaction of the meter), if the ignition is correctly timed. If the points open before the correct position, the timing is too far advanced. If they open when the piston is past it, the timing is retarded.
6. If adjustment is necessary, loosen the screw which secures the contact breaker points to the stator plate. This screw is accessible through a window in the flywheel. If the timing was advanced, decrease the point gap. If the timing was retarded, increase the point gap.
7. Repeat the procedure until the points open at the instant that the timing marks align.



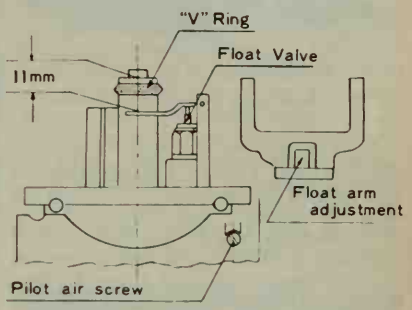
CDI Ignition Timing

F5 AND F7

These models are equipped with capacitor discharge ignition, which does not use contact breaker points. Instead, it has a signal generator which does not emit a pulse unless the engine is running. Therefore, ignition timing cannot be set statically as is the case with flywheel magneto and DC generator systems. It can only be observed with a stroboscopic timing light.

NOTE: *Since this system does not employ contact breaker points, it is not subject to their wear. As a result, once initial timing has been set (as it is at the factory) it very rarely requires adjustment.*

1. Remove the magneto cover, then connect a strobe light according to manufacturer's instructions.
2. Start and run the engine at 4,000 rpm.
3. Aim the strobe light beam at the marks on the flywheel and crankcase.
4. If the marks are in alignment at 4,000 rpm, no adjustment is necessary. If they are not aligned, stop the engine, insert a screwdriver blade through the hole in the magneto (see the illustration), and loosen screws "B," "C," and "D."
5. Shift the position of the magneto base by prying it with a screwdriver inserted into notch "A." To retard the timing, turn the base counterclockwise; to advance the timing turn it clockwise.
6. Tighten magneto base lockscrews "B," "C," and "D."
7. Start the engine up again and run it at 4,000 rpm. Recheck the mark alignment with the strobe light beam. Readjust again if necessary.



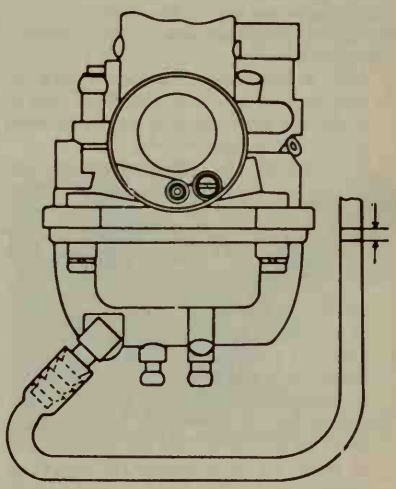
CDI magneto (F5 and F7)

CARBURETOR

Three adjustments to be made to the carburetor are float height, idle mixture, and idle speed. For the first of these, the carburetor must be removed from the machine except on F11, and KS125 models. On KS125, F11, and M series models, a special tool will be needed.

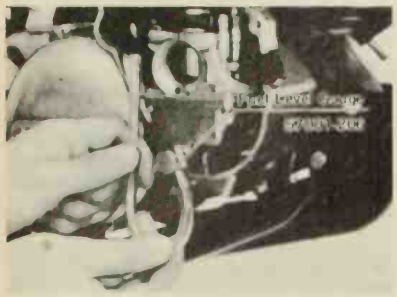
Adjusting Float Height

Refer to the "Carburetor Specifications" chart at the end of "Fuel Systems" for the correct float height for your model.



Float height adjustment—F5 only

F5



1. Remove the float bowl and turn the carburetor upside-down.
2. Measure the distance from the needle jet housing surface to each of the float arms.
3. If necessary, bend the adjustable tang to achieve the proper clearance.

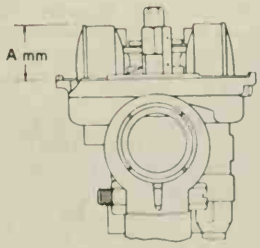
F11, KS125, AND M SERIES

1. M Series only: Remove the carburetor from the engine. Remove the float bowl and install the special tool in its place. Connect a fuel line to the carburetor fuel inlet.
2. F11 and KS125: Remove the main jet holder and the main jet from the float bowl as an assembly. Install the special tool into the float bowl.
3. Hold the sight tube of the special tool upright against the carburetor body. Turn the fuel on and observe the level of the fuel. The distance between the mating surface of the float bowl and the level of the fuel in the sight tube is the float height.

Fuel level measurement (F11, M, and KS Series)

Fuel level gauge installed (MC1 shown)

4. If adjustment is necessary, remove the float bowl. Push the float pivot pin out and remove the float. Be sure to catch the float needle as the float is removed.



5. Bend the tang on the float to effect adjustment. Bending the tang up toward the carburetor body will lower the float height (if the measurement was too small), and bending the tang away from the carburetor will have the opposite effect. Be careful to bend only the tang on the float.

OTHER MODELS

1. Remove the carburetor as outlined in the "Fuel Systems" section.

2. Turn the carburetor upside down, and remove the four float bowl screws carefully lifting off the float bowl.

3. Remove the float bowl gasket.

Float height

4. Float height can be measured with a steel rule or a vernier caliper. Float height is defined as the distance from the float bowl gasket surface (gasket removed), to the top of the float, when the tongue of the float arm is just touching the float needle.

NOTE: *Lower the float down until the tongue just contacts the float needle. Hold the float in this position, then measure the float height.*

5. Compare the value obtained with the correct specification for your machine. If the float height is too high or low, pull out the pin which holds the float in place, and bend the tongue very slightly to correct the adjustment.

NOTE: *If float height is too high, bend the tongue away from the carburetor body. If too low, bend it toward the carburetor body.*

6. Refit the float and recheck the adjustment.

CAUTION: *Bend only the float tongue to make an adjustment. Do not bend the float arms. The floats must be level. If the floats show different heights, the float assembly should be replaced. This indicates that the float assembly has been mishandled.*

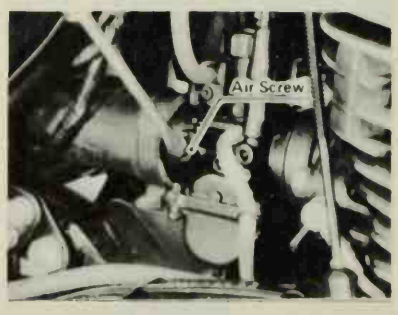
7. Float height will not be correct if the needle is worn or if there is foreign matter on the needle seat.

Throttle stop screw—KS125 and G series

Idle Speed and Mixture

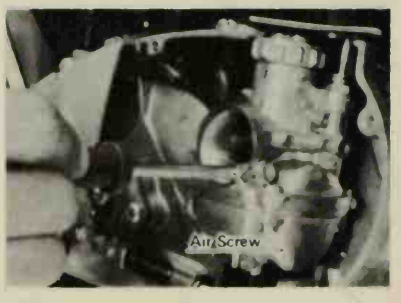
1. Ensure that the throttle cable adjustment is approximately correct so that the cable has enough slack to allow the throttle slide to be fully closed.

2. Screw the pilot air screw in (carefully) until it bottoms lightly, then turn it out the number of turns shown in the "Tune-Up Specifications" chart at the end of this section.



Throttle stop screw—MC1

3. Start the engine. When operating temperature is reached, adjust the throttle stop screw (if necessary), so that the engine idles as slowly as possible. Then turn the pilot air screw in or out until the engine runs smoothly. It should not be necessary to vary the air screw more than ½ turn in either direction from the given setting.



4. Adjust the throttle stop screw so that the engine idles at the desired rpm.

NOTE: *If proper idling cannot be obtained using this method, either the fuel system is clogged with dirt (check petcock, filter, float bowl), there is an air leak (manifold, cylinder head gasket, crankcase mating surfaces), or the engine has suffered mechanical damage (bad rings, leaking seals). The carburetor is the most likely source of poor idling.*

5. After idle speed and mixture are set, adjust the throttle cable and oil pump cable as outlined in the "Maintenance" section.

Pilot air screw location on F11 models

Pilot air screw location on rotary valve models

Tune-Up Specifications

Model	Breaker Point Gap (mm)	Ignition Timing (deg. mm) BTDC	Spark Plug (NGK)	Spark Plug Gap (mm)	Carburetor Air Screw (turns out)	Idle Speed (rpm)

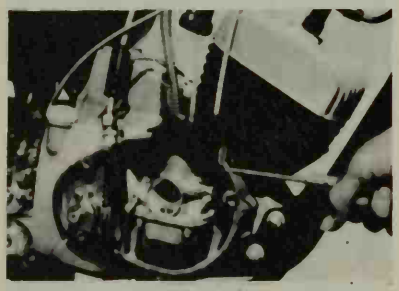
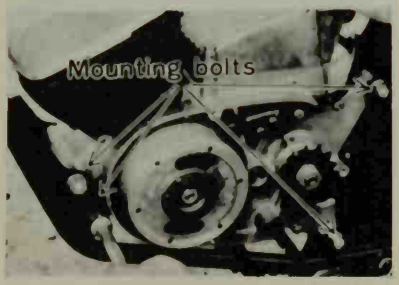
ENGINE AND TRANSMISSION



NOTE: *For engine component inspection techniques and procedures, refer to "Engine Rebuilding" under the General Information section. For engine specifications, refer to the charts at the end of this section.*

ENGINE REMOVAL AND INSTALLATION

Clean the engine thoroughly before removal to take away as much grease and road grime as possible. Be especially attentive to the cylinder base and the crankcase mating areas.

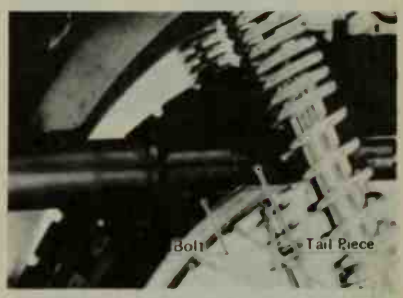


G Series

1. Warm the engine, and drain the transmission oil. Replace the drain plug.
2. Open the seat, and disconnect the battery negative terminal.
3. Remove the nuts or bolts which secure the exhaust pipe to the head. On G4TR and G5 models, disconnect the exhaust pipe retaining springs from the head. Remove the bolts which secure the muffler to the frame, and remove the exhaust system as a unit.
4. Remove the air cleaner (except GA series).
5. Slide the carburetor cap up on the cables. On older models the cap is secured with four phillips head screws, while on newer models, the rubber cap is secured in place with a spring clamp.
6. Remove the carburetor cover from the front right-side of the engine. Shut the fuel supply off at the fuel petcock and disconnect the fuel line from the carburetor. Remove the plug from the front of the right crankcase cover, and through the hole, loosen the carburetor clamp.
7. Lift the carburetor out of the case cavity and tie it aside. The carburetor starter and throttle cables can remain connected unless the carburetor is to be serviced. If the carburetor is to be serviced, unscrew the carburetor cap and pull out the throttle slide. The cable can then be disconnected and pulled through. To disconnect the starter cable, unscrew the cable guide and pull out the plunger.
8. Remove the oil pump cover from the rear of the right crankcase cover. Disconnect the oil pump cable from the oil pump control lever, then disconnect and plug the oil tank delivery line.
9. Loosen the locknut on the clutch adjuster, and screw the adjuster in to the case to allow plenty of cable free-play. Disconnect the cable from the clutch release mechanism, screw the adjuster out of the case and pull the cable through.
10. Remove the gearshift pedal pinch-bolt, then pull the pedal off its splined shaft. Remove the left crankcase cover.
11. Use pliers to remove the masterlink spring clip; remove the cover plate and the masterlink. Disengage the chain from the countershaft sprocket. Install the masterlink onto one end of the chain for safekeeping.

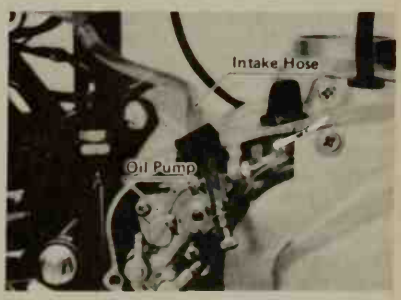
Loosening the carburetor clamp

12. Disconnect the magneto wiring and the neutral switch lead from the wiring harness near the battery. Disconnect the high-tension lead from the spark plug.
13. Remove the nuts and washers from the four engine mounting bolts. Remove the mounting bolts being careful not to damage the threads as the bolts are withdrawn.
14. Lift the engine out of the frame.



Remove the four engine mounting bolts

15. Installation is basically a reversal of the removal procedure. However, the following points should be noted:
    a. When installing the drive chain masterlink, make sure that the open end of the spring clip faces the opposite direction of chain rotation;
    b. Adjust the clutch, oil pump, throttle, and starter cables, drive chain free-play, and clutch release mechanism.
    c. Fill the transmission with the recommended amount and type of oil;
    d. Bleed the oil pump of any air bubbles.
    e. Make sure that the engine mounting bolts are tightened securely.

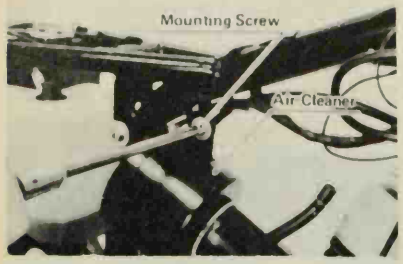


M Series

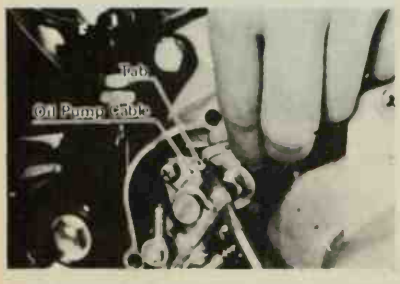
1. Warm the engine, hold the motorcycle upright, and drain the transmission oil. Replace the drain plug.
2. Remove the seat by first releasing the retaining band from the rear of the seat. Lift up on the rear of the seat and pull the seat off to the rear.
3. Disconnect the negative lead from the battery terminal.
4. Turn the fuel petcock to the off position and disconnect the fuel line. Unhook the retaining band from the rear of the fuel tank and pull the tank up and back to remove it.
5. Remove the bolt from the rear of the muffler and pull out the tail piece. Remove the bolts which secure the exhaust pipe to the head and the muffler to the frame. Remove the exhaust system.
6. Mark the position of the gearshift pedal in relation to the shift shaft. Remove the pinch-bolt and pull the gearshift pedal off the shift shaft.

Remove the bolt and pull the tail piece from the muffler

7. Remove the left crankcase cover.
8. Disconnect the magneto and neutral switch wiring from the wiring harness at the connectors near the ignition coil. Note whether the light blue or the yellow/green lead is not used. Undo any cable ties which hold the magneto wiring to the frame. Disconnect the high-tension lead from the spark plug.
9. Use pliers to remove the masterlink spring clip; remove the cover plate and masterlink. Disengage the chain from the countershaft sprocket. Install the masterlink onto one end of the chain for safekeeping.
10. Remove the oil pump cover from the rear of the right crankcase cover. Disconnect the intake hose from the oil pump. Pull the oil line and the rubber grommet from the case.
11. Pull off the oil tank cover and remove the air cleaner mounting screw.

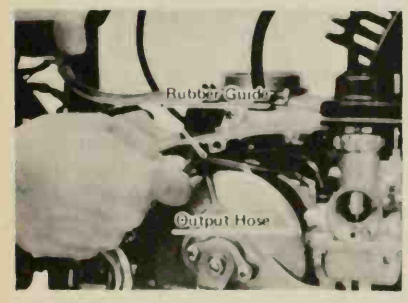


Disconnect the intake hose from the oil pump, then remove it and the rubber grommet from the case



12. Bend back the tab on the oil pump control lever and disconnect the oil pump cable.

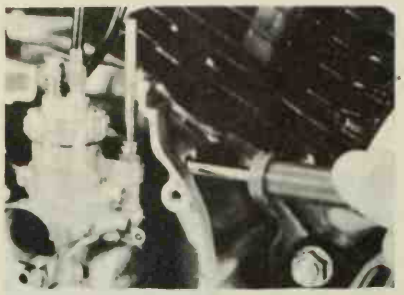
13. Remove the ring from the choke rod and slide the rubber carburetor cap up on the cables, and remove the carburetor cover from the right crankcase cover.



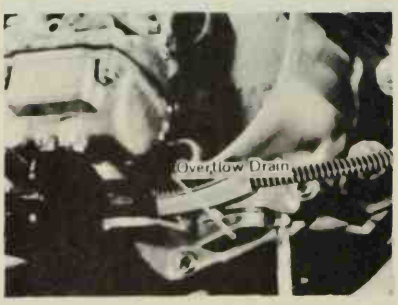
14. Remove the oil pump output hose from the rubber grommet in the right crankcase cover. Screw the oil pump cable adjuster out of the crankcase cover and remove the cable.

Remove the air cleaner mounting screw

Bend back the locking tab and disconnect the oil pump cable

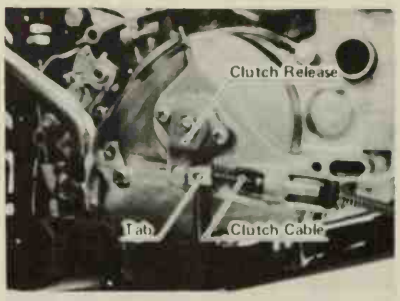


Remove the output hose from the rubber guide



15. Disconnect the fuel line from the carburetor. Remove the plug from the front of the right crankcase cover, and through the hole, loosen the carburetor clamp.

16. Lift the carburetor out of the right crankcase cover and tie it aside. The throttle cable can remain connected unless the carburetor is to be serviced. If it is to be serviced, unscrew the carburetor cap and pull out the throttle slide. The cable can then be disconnected and pulled through.



17. Remove the carburetor overflow drain from the bottom of the right crankcase cover.

Loosening the carburetor clamp through the hole in the right crankcase cover

Removing the carburetor overflow drain

To disconnect the clutch cable, bend back the locking tab on the clutch release

18. Loosen the locknut on the clutch release mechanism, and loosen the adjusting screw 2 or 3 turns. Pry open the locktab on the clutch release lever and disconnect the clutch cable. Remove the spring from the end of the cable, and free the cable from the case.

19. Remove the nuts and washers from the four engine mounting bolts. Slide the mounting bolts out taking care not to damage the threads on the bolts. Lift out the engine from the right-side.

20. Installation is basically a reversal of the removal procedure. However, note the following points:

a. The lower rear mounting bolt is installed from the right-side the other bolts are installed from the left;

b. When installing the masterlink spring clip, make sure that the open end faces the opposite direction of chain rotation;

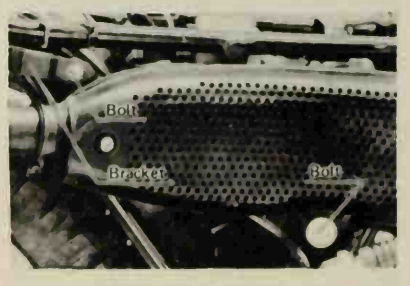
c. Secure the ends of the oil pump, and clutch cables with the locking tabs;

d. Make sure that the carburetor is properly installed and the clamp is tight enough to prevent any air leaks;

e. Make sure that the rubber extender on the carburetor cap is properly fitted to the idle screw when the carburetor cap is installed;

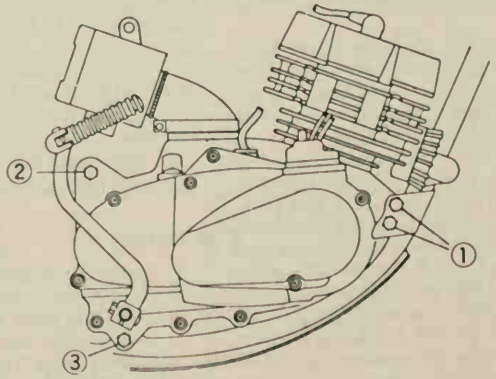
f. Adjust the clutch cable, oil pump cable, throttle cable, drive chain freeplay, and clutch release mechanism;

g. Bleed the oil pump of any air bubbles. Refer to "Lubrication System:"



h. Torque the engine mounting bolts to 26–28 ft lbs.

KS125



1. Warm the engine, hold the motorcycle upright, and drain the transmission oil. Replace the drain plug.

2. Remove the seat. Disconnect the negative lead from the battery.

3. Turn the fuel petcock off and disconnect the fuel line. Unhook the retaining band from the rear of the fuel tank and pull the tank up and back to remove it.

Muffler mounting bolts

MC1 engine mounting bolts

4. Remove the two nuts which secure the exhaust pipe to the head. Remove the two bolts which secure the muffler to the frame. Remove the exhaust system.

5. Mark the position of the gearshift pedal in relation to the shift shaft. Remove the gearshift pedal pinch-bolt, and pull the gearshift pedal from the shift shaft.

6. Remove the left rear crankcase cover.

7. Use pliers to remove the masterlink spring clip; remove the cover plate and masterlink. Disengage the chain from the countershaft sprocket.

8. Remove the oil pump cover. Bend back the locking tab on the oil pump control lever and disconnect the oil pump cable. Unscrew the oil pump cable adjuster out of the crankcase and pull the cable free of the case.

Plug the oil tank outlet by connecting the breather tube to it

9. Remove the oil tank cover. Remove the three mounting bolts from the oil tank, and pull the oil tank out of the frame. Disconnect the outlet line from the bottom of the tank, and connect the breather tube to the oil tank outlet. The outlet line can be plugged with a small screw.

The clutch cable bracket is removed with the magneto cover

10. Remove the clutch cable bracket and the magneto cover. Remove the cotter pin and disconnect the clutch cable from the clutch release mechanism.

11. Disconnect the two magneto output leads at the connectors near the frame backbone. Remove any cable ties which secure the magneto wiring to the frame. Disconnect the high-tension lead from the spark plug.

12. Disconnect the brake light switch spring from the brake pedal and the brake pedal return spring from the frame, then the pedal

13. Loosen the rear brake adjusting nut at the end of the cable to allow plenty of free-play in the cable. Remove the cotter pin from the pin which holds the inner brake cable to the frame, then remove the pin.

To disconnect the rear brake outer cable, remove the screw, washer, and retaining plate

14. Remove the screw, washer, and outer cable retaining plate from the brake pedal. Disconnect the outer cable from the brake pedal. Remove the brake pedal.

15. Remove the four bolts from the carburetor rim, and slide the rim and rubber cap up the carburetor cables. Remove the carburetor cover and the rubber grommet from the right crankcase cover.

16. Loosen the air cleaner tube clamp.

17. Pull the carburetor out of the case and tie it aside. The carburetor starter and throttle cables can remain connected unless the carburetor is to be serviced. If it is to be serviced, unscrew the carburetor cap and pull out the throttle slide. The cable can then be disconnected and pulled through the cap. To disconnect the starter cable, unscrew the starter plunger cap and pull out the plunger.

18. Unscrew the tachometer cable retaining screw from the crankcase and pull the tachometer cable free of the case.

19. Remove the nuts and washers from the four engine mounting bolts. Slide the mounting bolts out taking care not to damage the threads on the bolts. Lift out the engine from the right-side.

20. Installation is basically a reversal of the removal procedure. However, note the following points:

a. When installing the masterlink spring clip, make sure that the open end faces the opposite direction of chain rotation;

b. Install the engine mounting bolts from the right-side. Tighten the two 17 mm nuts to 23–30 ft lbs and the two 13 mm nuts to 14.5–16 ft lbs;

c. Secure the oil pump cable to the oil pump control lever with the locking tab on the lever;

d. Make sure that the air cleaner tube fits properly on the air cleaner body; secure the tube with a clamp;

e. Adjust the clutch, oil pump, and throttle cables, drive chain free-play, and clutch release mechanism;

f. Bleed the oil pump of any air bubbles. Refer to "Lubrication System."

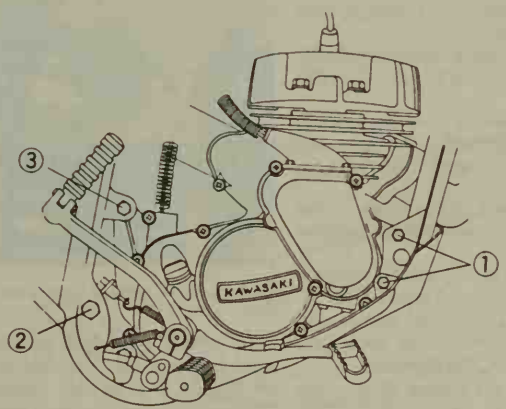
F Series

1. Warm the engine and drain the transmission oil. Replace the drain plug.

2. Open the seat and disconnect the battery.

3. Turn the fuel petcock to the off position (except F5 and F7), and disconnect the fuel line from the petcock. On F5 and F7 models, disconnect the vacuum line from the fuel petcock.

4. Remove the mounting bolts from the muffler. Remove the nuts or springs which secure the exhaust pipe to the head. Remove the exhaust system.



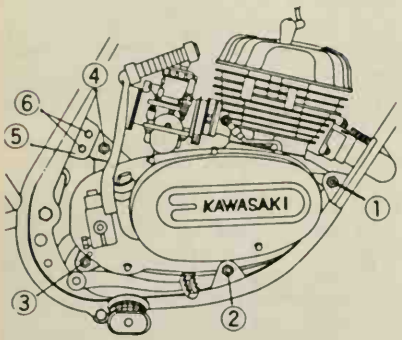
5. Remove the air cleaner (except F11).

6. All rotary valve models: Remove the carburetor cover from the right crankcase cover and slide the rubber carburetor cap up on the control cables. Disconnect the fuel line from the carburetor. Lift the carburetor out of the case cavity and tie it aside.

7. F11 only: Loosen the hose clamp on either side of the carburetor and pull the carburetor off to the rear.

8. The carburetor starter and throttle cables can remain connected unless the carburetor is to be serviced. If it is to be serviced, unscrew the carburetor cap and pull out the throttle slide. The cable can then be disconnected and pulled through the cap. To disconnect the starter cable, unscrew the starter plunger cap and pull out the plunger.

9. Remove the gearshift pedal pinch-bolt, then pull the shift pedal off its shaft. Remove the chaincase cover with the clutch cable still attached and place it out of the way.



Engine mounting bolts (KS125)

10. Use pliers to remove the masterlink spring clip; remove the cover plate and the masterlink. Disengage the chain from the countershaft sprocket. Install the masterlink onto one end of the chain for safekeeping.

11. On F11 models, remove the connector panel and disconnect the red connector from it. On other models, disconnect the magneto and neutral switch wiring from the connectors near the back of the engine. Disconnect the high-tension lead from the spark plug.

12. Remove the four engine mounting bolts being careful not to damage the threads on the bolts. On F11 models, also remove the bracket from the right upper rear mount.

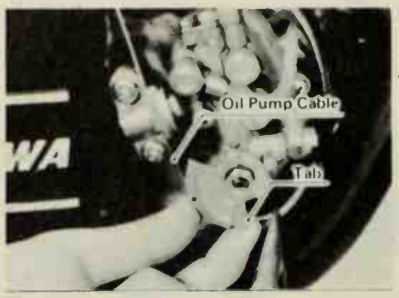
13. Lift the engine out of the right-side of the frame.

Engine mounting bolts (F11)

Engine mounting bolts (F Series except F11)

14. Installation is basically a reversal of the removal procedure. However, note the following points:

a. Install the engine mounting bolts from the left-side and torque them to 19–25 ft lbs;



b. When installing the masterlink spring clip make sure that the open end faces the opposite direction of chain rotation;

c. Secure the oil pump cable to the oil pump control lever with the locking tab on the lever;

d. Fill the transmission with the recommended amount and type of oil;

e. Adjust the clutch, oil pump, and throttle cables, drive chain free-play, and clutch release mechanism;

f. Bleed the oil pump of any air bubbles. Refer to "Lubrication System."

Secure the oil pump cable with the locking tab on the control lever

TOP END

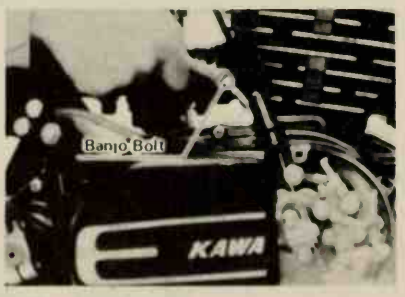
1. All models use through-studs, anchored in the crankcase, to secure the head and cylinder. The top end components may be removed with the engine in the frame.

2. Before beginning, have on hand the following spare parts: cylinder head and cylinder base gaskets; wrist pin circlips (these should be replaced if they are removed); exhaust pipe gasket; and piston rings (if removed).

Top End Removal

1. Clean the engine thoroughly to remove any dirt or deposits. The area around the cylinder base is especially important.

2. Remove the spark plug.



3. Disconnect the exhaust pipe from the cylinder. Remove the exhaust system.

4. On the F11 models, remove the carburetor from the cylinder.

5. Loosen the four cylinder head nuts (and four head bolts—F11, F5, and F8), ¼ turn at a time in an "X" pattern until they are all loose, then remove them and their washers from the studs.

6. Remove the cylinder head and the head gasket as well.

NOTE: *The cylinder head may become stuck to the cylinder due to carbon build-up. In this case, tap around the lower edge of the head with a plastic mallet until the head is free. Do not strike the cooling fins.*

Disconnect the oil feed banjo from the F11 cylinder

7. On F11 models, disconnect the oil feed banjo at the cylinder. Wrap a piece of plastic around the banjo, bolt, and washers. Secure it with a rubber band to prevent the entry of dirt.

Using the factory tool to remove the wrist pin (F11 shown)

8. Place the piston at top dead center and lift the cylinder off the crankcases until there is enough room to stuff a clean rag between the cylinder and the cases. Pull the cylinder straight up, catching the piston with one hand when the cylinder is free so that the piston won't hit the studs or the cases.

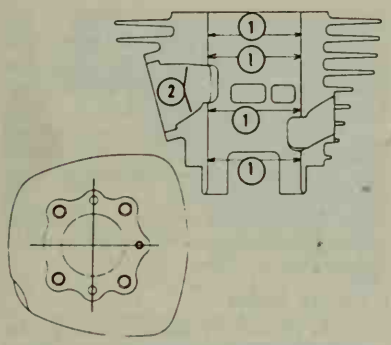
NOTE: *If the cylinder is stuck, it may be freed by tapping around the bottom with a plastic mallet.*

9. Remove and discard the cylinder base gasket.

10. Remove the wrist pin circlips with a pair of needlenose pliers. The rag should remain in place while doing this to prevent the clips from falling into the crankcase. Grasp the piston with one hand and push the wrist pin out using a suitable drift. If the pin resists removal, it is advisable to use the factory wrist pin removal tool. This consists of a steel band or bands which fit around the piston while the attached screw device is used to push the pin out.

Alternatively, heat the piston crown gently with a propane torch which may facilitate wrist pin removal.

11. When the wrist pin is about ¾ in. out of the piston, grasp the exposed end with a needlenose pliers, and pull it out until it is clear of the connecting rod. Remove the piston from the engine.



CAUTION: *Never strike the wrist pin or attempt to use brute force to drive it out. The connecting rod may be bent in the attempt.*

Cylinder and Piston

1. To check for wear of the bore, use an inside micrometer and take bore diameter measurements at the following points, holding the instrument in line with the intake and exhaust ports: just below the top edge of the cylinder; just above the exhaust port; just below the lower edge of the exhaust port; just above the top edge of the cylinder spigot. Record the diameters. Then turn the micrometer 90° and take another set of readings at the same points.

2. If the difference between the highest and lowest of these eight measurements exceeds 0.05 mm (0.0019 in.), the cylinder should be bored and the next oversize piston fitted (see below).

3. Make a visual inspection of the piston. If score marks are deeper than 0.002–0.003 in. or if a scored area is wider than 0.5 in., it is recommended that the piston be replaced.

Measure the cylinder bore in both planes at the four places shown (1)

4. Check that the piston rings are free in their grooves and that the grooves have not been closed up by having metal pushed into them as might occur if the piston has seized.

5. Measure the diameter of the piston perpendicular to the wrist pin at a point 5 mm above the bottom edge of the piston skirt. Compare this reading of the piston diameter with the *smallest* of the cylinder bore measurements made earlier. Subtracting the piston diameter from the smallest of the bore measurements will give the piston-to-cylinder clearance. If the measured value is more than 0.1 mm (0.0039 in.), the cylinder should be bored and the next oversize piston fitted.

6. If the cylinder must be bored, first obtain the correct oversize piston and rings. For most models, pistons are available in 0.5 and 1.0 mm oversize.

Measure the diameter of the new piston, add the correct clearance for your model given in the "Engine Specifications" chart at the end of this section, and have the cylinder bored to the sum of the two.

After boring, the difference between the largest and smallest cylinder bore diameters should not exceed 0.01 mm (0.0004 in.).

After the cylinder is bored, use a small file to put a slight chamfer on the edges of all the ports. This is important since rings will catch on the edges of unchamfered ports.

7. Two checks which must be made to the piston rings are end gap and side clearance for plain-type rings. This is true of both new and used rings. If the rings are installed on the piston, check side clearance first.

8. Check side clearance for each ring by inserting the proper size feeler gauge between the ring and the ring groove. Clearance is given in the chart at the end of this section for models where side clearance is specified. If old rings do not have the correct side clearance, they will have to be replaced. If new rings show the wrong clearance, the piston will have to be replaced, since either the ring grooves are worn (clearance too large), or have been closed up by piston seizure.

9. Piston ring end-gap checking necessitates removing the rings from the piston. To do this, gently spread the ring apart with your thumbs on the end-gaps, and move the other end of the ring up over the piston with the index fingers. Installation is simply the reverse.

Note the presence of any expanders behind the rings.

10. First check the rings for a twisted or warped condition. Replace the rings if they are deformed.

11. Both used *and* new rings should be checked for end-gap.

Place each ring into the bottom of the cylinder bore, and then push it into the bore an inch or so using the piston crown. This will ensure that the ring is aligned perpendicular to the cylinder wall.

Check that the ring is contacting the cylinder wall at all points. Place a piece of white paper beneath the cylinder and see if anything is visible between the cylinder wall and the ring. If you can see the white paper, the ring is not touching the wall either because it is deformed or worn, or because the cylinder wall has become oval through wear.

12. Check the ring end-gap with the proper feeler gauge. Refer to the "Engine Specifications" chart at the end of this section for the correct gaps for you machine.

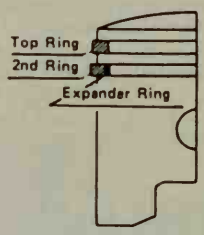
13. If the gap is too large, the rings must be replaced. If too small, hold the ring so that *both* ends are bearing against the sides of a small fine flat file. After a few strokes of the file, recheck the gap. Continue the filing procedure until the end-gap is correct.

14. Clean out the ring grooves with a very thin screwdriver. Plain-type ring grooves can be cleaned with a piece of broken ring. Other types, however, should not be cleaned in this manner. Be careful not to scratch or gouge the groove surfaces.

15. Inspect the wrist pin for wear or scoring. Any blueing or burned marks, which would indicate inadequate lubrication or extreme engine heat, means that the wrist pin and possibly the connecting rod bearing should be replaced. Check that the pin has not been worn or scored in the area which contacts the bearing.

NOTE: *Where possible, use a marked pin with an "A" piston and an unmarked wrist pin with a "B" piston.*

16. The connecting rod small end needle bearing can be removed from the rod by hand. Needle bearings exhibiting flat spots or pitting on the rollers or races should be replaced along with the wrist pin.

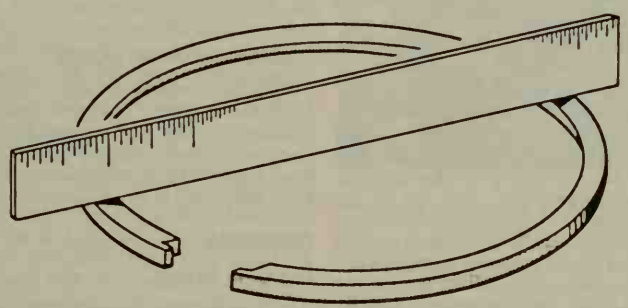


17. Check the vertical play in the wrist pin. Maximum is 0.045 mm (0.002 in.). If it is in excess of this, the bearing and pin should be replaced.

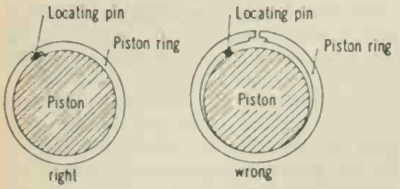
18. Lightly oil the wrist pin and insert it into the piston. The pin should be a snug push fit. Note the amount of drag on the pin while attempting to push it in by hand. If the pin goes in easily, or can be easily turned after insertion, either it or the piston will have to be replaced. Piston-to-pin clearance is 0.002–0.008 mm (0.00008–0.00032 in).

19. To check for connecting rod straightness, fit the piston, minus the rings, onto the connecting rod and install the wrist pin. Install the cylinder. The piston should be dead center in the cylinder bore. If moved to either side, it should return to the center postion after the engine is turned over once or twice. If it does not, or if it appears to be to one side or the other in the bore, the connecting rod is bent.

Top End Assembly



1. Refit the piston rings to the piston. Be sure to fit an expander ring behind the second and third rings of the F5 piston, and behind the second ring of F6, F7, F8, and KS-series pistons. Both rings on M-series pistons are of the "Keystone"-type, while only the top ring of F-11 and KS series models is of the "Keystone"-type.

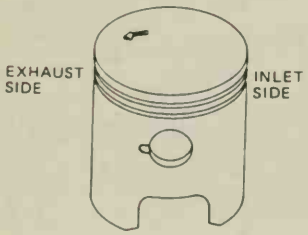


Piston ring locations

Install the rings with the manufacturer's stamped mark facing up

Checking piston ring for a bevelled edge

Ensure that the ring ends are positioned on either side of the locating pins



On models with one "Keystone" ring, the top and second rings look almost identical, but are not interchangeable as the top ring groove in the piston is also bevelled. Before installing the top ring, hold it on a straightedge: the bevelled edge should be clearly visible. Install the rings with the manufacturer's stamped mark (stamped near the end-gap) facing up, and the end-gap over the locating pins in the ring grooves.

2. Install a new wrist pin circlip into one side of the piston. Lubricate the wrist pin and install it into the other side of the piston until about 1/16 in. of the wrist pin is visible protruding from the inside of the wrist pin hole. The wrist pin should be a push-fit.

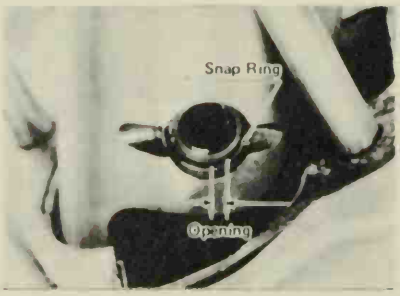
3. Lubricate the small end needle bearing and install it into the connecting rod.

4. Place the piston over the connecting rod so that the arrow stamped on the top of the piston crown is pointing toward the front of the engine (exhaust side).

5. Carefully line up the wrist pin with the connecting rod small end needle bearing, and push the wrist pin through until it is centered between the circlip grooves.

The arrow on the piston crown should point toward the exhaust port

6. New wrist pin circlips must be used in place of ones which were removed. Install the remaining circlip into the piston and rotate both circlips in their grooves so that the opening in the circlip is either positioned at the top or bottom of the circlip groove.



7. Lightly lubricate the piston rings and piston skirt with two-stroke oil.

8. Install a new cylinder base gasket, making sure that it is correctly installed.

9. Place the piston at bottom dead center. Align the piston rings so that the ring ends are directly over the locating pin in the ring grooves.

10. Take up the cylinder, make sure that the cylinder walls are lightly coated with oil, and fit the cylinder on the crankcase studs.

11. Lower the cylinder over the piston while compressing the piston rings with your fingers until the piston rings have fully entered the bore.

The opening in the circlip must face either up or down

12. Make sure that the cylinder is properly seated in the crankcase. Install the head gasket making sure that it is properly positioned: the holes cut in the gasket should line up perfectly with the stud holes and the bore in the cylinder.

13. Refit the cylinder head, cylinder head washers, nuts, and head bolts (if fitted), and tighten them in an "X" pattern in increments of 2–3 ft lbs to the proper torque. The proper torque specification for your model can be found in the "Engine Torque Specifications" chart at the end of this section.

14. The remainder of the assembly procedure is the reverse of disassembly.

ENGINE CASE ASSEMBLIES

The following sections deal with service to the engine crankcase cover assemblies: magneto, countershaft sprocket, clutch, primary drive, rotary valve assembly (if fitted), external shifter linkage, and so on.

On all models the magneto is located on the left-side of the crankshaft; the clutch is on the right-side of the engine, as is the primary drive, and the countershaft sprocket is on the left.

On all models so equipped, the rotary valve assembly is located on the right end of the crankshaft.

a. A puller will be needed to remove the magneto rotor;

b. The clutch on all models is the wet-type. Transmission oil must be drained before removing the right crankcase cover. In addition, a new crankcase cover gasket should be used upon reassembly.

Left Crankcase Cover

The left crankcase cover contains the flywheel magneto and the countershaft sprocket. G and M Series models use a one-piece cover, whereas the F and KS Series models are equipped with a magneto cover and a chaincase cover.

REMOVAL

G and M Series

1. Use a center punch to place aligning marks on the shift shaft and the shift lever so that the lever can be installed in the same position. Completely remove the shift lever pinch-bolt, then spread the clamp open slightly with a screwdriver and pull the lever off the shaft.

2. Remove the left crankcase cover securing screws by breaking each one loose with an impact driver. When all of them are loose remove them.

3. Pull the cover off the engine. If the cover is stuck, tap around the sides with a plastic mallet.

F and KS Series

1. On F6 and F7 models, remove the contact breaker cover securing screws and the cover.

2. On KS series models remove the two screws which secure the clutch cable bracket to the crankcase cover. Disconnect the clutch cable.

3. Remove the chaincase cover screws with an impact driver, then lift the cover off the engine. On F Series models, tie the cover out of the way with the clutch cable attached.

4. Remove the magneto cover screws with an impact driver, then lift the cover off the engine.

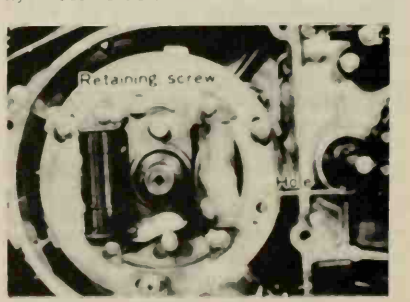
INSTALLATION

All Models

Installation is a reversal of the removal procedures. Note the following points.

1. Inspect the condition of the shift shaft oil seal. If the lips of the seal appear to be torn or damaged in any way, replace the seal.

2. Tighten all of the cover screws evenly to prevent warping the cover.



Magneto

REMOVAL

To remove the magneto flywheel two special tools are needed. One of these is used to hold the flywheel from turning while the securing nut is removed, and the other is a puller to pull the flywheel off the tapered end of the crankshaft.

1. Remove the left crankcase cover as described previously.

2. While holding the flywheel from rotating, remove the securing nut from the end of the crankshaft. On F7, F8, and F5 models, the flywheel can be secured by inserting a screwdriver through a hole in the flywheel and into a hole in the stator. On other models use the factory magneto flywheel holder.

On F5, F7, and F8 models, the flywheel can be held by inserting a phillips head screwdriver through the hole in the flywheel into the hole in the stator base

Typical magneto flywheel holder (KS125 shown)

Typical magneto flywheel puller (KS125 shown)

3. Use the special puller, available at Kawasaki dealers, to pull the flywheel off the crankshaft. Remove the key from the crankshaft.

NOTE: *If the flywheel resists removal, tighten the puller as much as possible, then give the end of the puller a sharp rap with a hammer which should break it loose.*

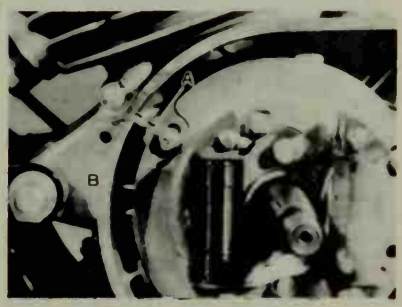
CAUTION: *Do not strike the flywheel itself as this may decrease its magnetic properties.*

4. To remove the stator from the crankcase, first disconnect the magneto wiring from the wiring harness and the neutral switch. Then remove the securing screws from the stator base and remove the stator.

INSPECTION

1. Magneto electrical tests can be found in the "Electrical Systems" section.

2. Handle the magneto rotor carefully. Do not drop or strike it as this may decrease its magnetic properties.



3. Check the rotor for loose hub rivets or cracks. Check the inside of the rotor and note any scoring which may have been caused by contact with the stator coil cores. If such scoring exists, the cause must be determined and remedied.

4. Check the stator assembly for any damage visible to the eye such as scored coil core ends, broken or frayed wiring, loose coils, etc.

5. The tapered portion of the crankshaft should be smooth and free of corrosion, rust, etc. Finish off any scratches or scores with fine emery cloth. Clean the area thoroughly.

6. Check the end of the crankshaft for play which would indicate a bad crank bearing. This is one thing which would cause the rotor to strike the coil cores.

7. Check the woodruff key for condition and replace it if step-wear has taken place or if the key is too loose in the keyway.

On F5, F7, and F8 models, align the marks "A" and "B" when installing the stator base

INSTALLATION

1. Installation is the reverse of removal.

2. On F7, F8, and F5 models, make sure that marks "A" and "B" on the stator and crankcase align.

3. Do not forget to install the woodruff key. Apply some oil or grease to the crankshaft taper.

4. Push the rotor on by hand after lining up the rotor slot with the key.

5. Use the rotor nut to seat the rotor. Do not strike the rotor.

Countershaft Sprocket

REMOVAL

1. Remove the left crankcase cover or the chaincase cover.

2. With a hammer and punch, bend down the tab on the countershaft sprocket nut washer.

3. Loosen the sprocket nut. If the engine is in the frame, the sprocket may be held while doing this by applying the rear brake hard. If the engine is not in the frame, loop a length of old drive chain around the sprocket and clamp the ends in a vise. Then remove the nut.

4. If the drive chain is still connected, disconnect it at this point. Remove the sprocket.

INSTALLATION

Installation is the reverse of the removal procedure. Ensure that the sprocket nut is firmly tightened and that the tab on the washer is bent up across one of the nut flats. On M Series models, make sure that the projection on the sprocket washer is fitted into the hole in the sprocket.

Right Crankcase Cover

REMOVAL

G and M Series

1. Drain the transmission oil.

2. Use a center punch to place a set of aligning marks on the kick-starter and the kick-starter shaft so that the kick-starter can be installed in the same position. Completely remove the pinch-bolt from the kick-starter, spread the clamp with a screwdriver and pull the kick-starter off its shaft.

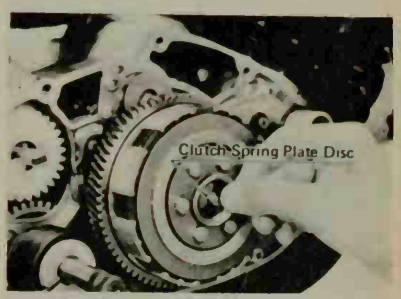
3. Remove the carburetor cover securing screws with an impact driver, then lift off the cover.

4. Remove the carburetor securing screw at the front of the crankcase.

5. Turn off the fuel petcock and disconnect the fuel delivery line at the carburetor.

6. Remove the carburetor and tie it aside with cables connected unless it requires servicing.

7. Loosen the clutch release locknut, and back the adjusting screw out a few turns. Disconnect the clutch cable from the clutch release mechanism.



8. Remove the oil pump cover securing screws with an impact driver, then lift off the cover.

9. Disconnect the oil pump cable and disconnect and plug the oil tank delivery line.

10. On M Series models, remove the side stand and footrest assembly by removing the four bolts which secure it to the frame. Place a crate or another suitable object beneath the engine to hold the motorcycle upright.

Footrest assembly mounting bolts (MC1)

Remove the clutch spring disc so that it is not misplaced

11. Remove the crankcase cover securing screws with an impact driver, then lift off the crankcase cover. It is not necessary to remove the oil pump or the clutch

release mechanism unless they require servicing.

12. Remove the clutch spring plate disc from the center of the clutch and set it aside for safekeeping.

F Series (Except F11)

The procedure for these models is the same as that for the G and M Series, with the exception that the clutch release mechanism is located on the other side of the engine.

F11

1. With the motorcycle in the fully upright position, drain the transmission oil.

2. Remove the oil pump cover, and remove the rubber grommet from the crankcase cover.

3. Disconnect the tachometer cable by unscrewing it from the crankcase cover.

4. Straighten the locking tab on the oil pump lever, and disconnect the oil pump cable from the oil pump lever. Loosen the locknut on the oil pump cable adjuster, and screw the adjuster out of the crankcase cover.

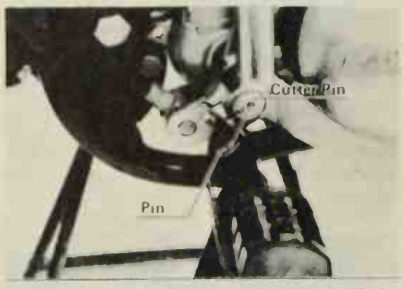
5. Using a center punch, place a set of aligning marks on the kick-starter and the kick-starter shaft so that the kick-starter can be installed in its original position. Completely remove the pinch-bolt from the kick-starter. Spread the kick-starter with a screwdriver and pull it off its shaft.

6. Disconnect the brake light switch spring from the brake pedal. Loosen the brake cable adjusting nut to allow plenty of free-play at the pedal, then remove the pinch-bolt from the brake lever and remove the brake pedal.

Plug the inlet tube with a small screw so that no oil will leak

7. Disconnect the oil inlet tube from the oil pump and plug it to prevent oil from leaking. Remove the oil line from the cylinder at the banjo bolt.

8. Remove the nine crankcase cover screws and remove the crankcase cover and gasket from the crankcase.



KS125

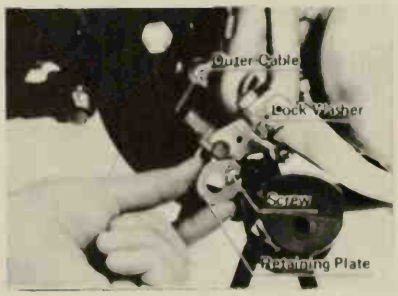
1. Hold the motorcycle upright and drain the transmission oil.

2. Remove the exhaust pipe after removing two nuts from the exhaust collar and two bolts which secure the muffler to the frame.

3. Using a center punch, place a set of aligning marks on the kick-starter and the kick-starter shaft so that the kick-starter can be installed in its original position. Completely remove the pinch-bolt from the kick-starter. Spread the kick-starter with a screwdriver and pull the kick-starter off its shaft.

4. Disconnect the brake light switch spring from the brake pedal and the brake pedal return spring from the frame, then the pedal.

Remove the cotter pin and the pin which holds the inner cable to the frame



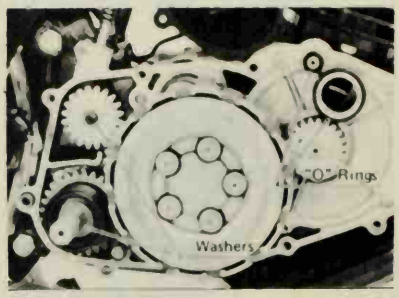
5. Loosen the rear brake adjusting nut at the end of the cable to allow plenty of free-play in the cable. Remove the cotter pin from the pin which holds the inner brake cable to the frame, then remove the pin.

6. Remove the screw, washer, and outer cable retaining plate from the brake pedal. Disconnect the outer cable from the brake pedal. Remove the brake pedal.

7. Remove the four bolts from the carburetor rim and slide the rim and rubber cap up the carburetor cables. Remove the carburetor cover and the rubber grommet from the right crankcase cover.

8. Shut off the fuel at the petcock and disconnect the fuel line from the carburetor. Pull the carburetor out of the crankcase and place it out of the way with the cables still attached.

9. Disconnect the oil line from the crankcase cover by removing the banjo bolt. Take care not to lose the two washers fitted to either side of the banjo.



To disconnect the outer cable, remove the screw, washer, and retainer plate

Disconnect the oil line at the banjo bolt. Take care not to lose the two washers located on either side of the banjo fitting.

10. Remove the three screws which secure the air duct to the air cleaner tube. Remove the nine crankcase cover securing screws, and pull the right crankcase cover from the engine. Remove the right crankcase cover gasket.

11. Make sure that the washers on the kick shaft and the oil pump gear shaft and the O-rings on the intake port and the oil passage are not misplaced.

When the right crankcase cover is removed, take care not to misplace the O-rings and washers

INSTALLATION

All Models

Installation is a reversal of the removal procedures. Note the following:

1. Use a new case cover gasket on reassembly.

2. Examine the kick-starter shaft oil seal and replace it if necessary.

3. Make sure that the clutch spring plate disc is installed in the center of the clutch (G and M Series).

4. Make sure that the oil pump drive gears mesh properly when the cover is installed.

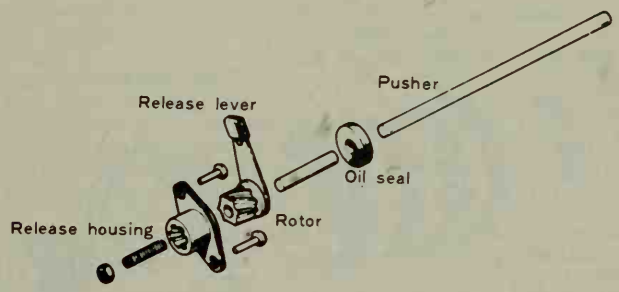
5. Make sure that the oil drain under the carburetor is not blocked.

Clutch Release Mechanism

G AND M SERIES

Refer to the following section for the "F Series Clutch Release Mechanism." The only difference on the G Series is that the mechanism is located on the opposite side of the engine (under the carburetor cover) and, as a result, the two pushrods on the F Series are not needed.

F SERIES



Removal

1. Remove the chaincase cover as described previously.

2. Remove the two clutch release mechanism housing mounting screws.

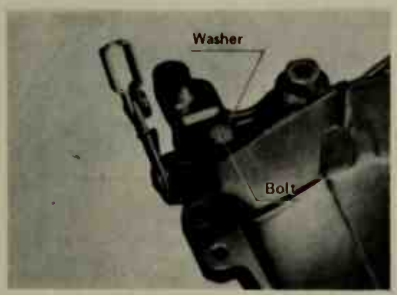
Removing the clutch release mechanism

Clutch release mechanism (F Series shown)

3. Remove the housing from the case cover and pull the short pushrod out through the oil seal.

Inspection

1. Inspect the release lever and release housing for excessive wear, scoring, or any other signs of damage. Replace as necessary.
2. Inspect the short pushrod for deformed ends or a bent condition. Replace as necessary.



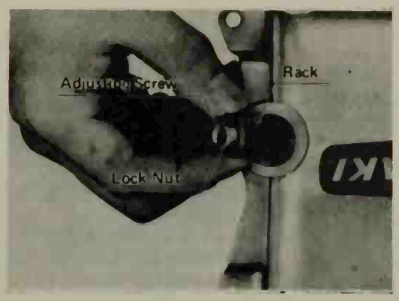
Installation

Installation is a reversal of the removal procedure. When assembling the inner and outer release, set the lever angle at approximately 90° to a line drawn through the two mounting screws so that the correct clutch adjustment can be achieved.

KS125

Removal

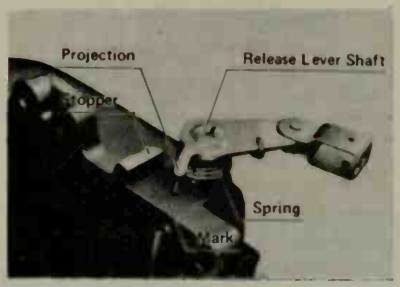
1. Remove the chaincase cover.
2. Remove the clutch cable bracket and the magneto cover. Remove the cotter pin from the release lever and disconnect the clutch cable.



Clutch release mechanism bolt and washer—KS125

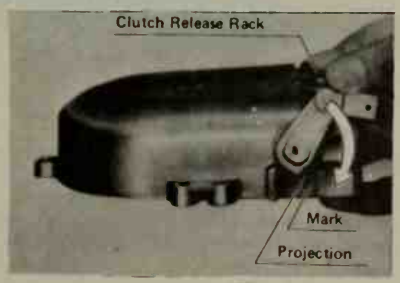
3. Bend back the tabs on the lockwasher and remove the clutch release mechanism bolt from the inside of the magneto cover. The clutch release lever shaft can now be removed from the magneto cover.
4. Remove the clutch adjusting hole cap, and remove the adjusting screw, locknut, and clutch release rack.

Inspection



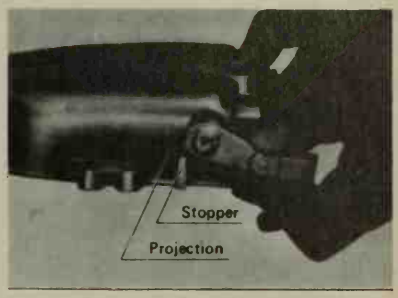
1. Inspect the teeth on the release rack and the lever shaft. If the teeth are damaged both components should be replaced.

The locknut, adjusting screw, and release rack are removed through the access hole



Installation

1. Grease the lever shaft and the release rack. At the same time fill the two holes inside the magneto cover with grease.
2. Hook the return spring onto the release lever and insert the lever shaft partway into the magneto cover. Do not insert the lever shaft into the cover far enough for the stopper on the cover to interfere with the projection on the release lever when the lever is rotated.

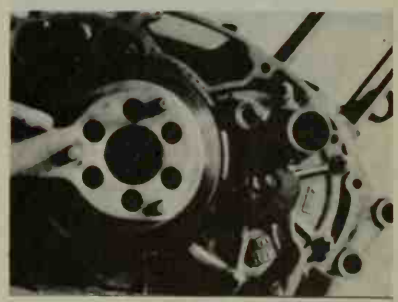


Insert the lever shaft partway into the cover with the projection aligned with the mark on the cover

3. With the projection on the release lever pointing to the mark on the magneto cover, insert the release rack into the clutch adjusting hole. While applying hand pressure on the rack, rotate the release lever to the position shown in the accompanying illustration, then insert it all the way into the magneto cover.

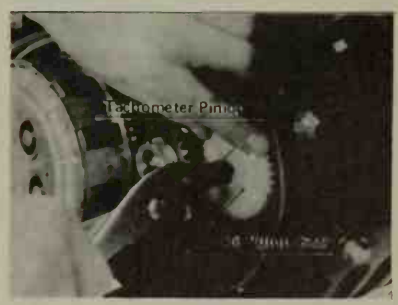
Installing the release rack

When the lever shaft is rotated to this position, push it all of the way into the cover



4. Install the clutch release mechanism bolt and washer, and bend the washer up against a flat on the head of the bolt.
5. The remainder of installation is in the reverse order of removal. When installation is complete, adjust the clutch as described in "Maintenance."

Primary Gear



REMOVAL

F5 and F8

1. Remove the left crankcase cover as described previously.
2. Bend back the oil pump pinion securing nut lockwasher, then install the clutch holding tool or stuff a rag between the primary and the clutch housing gear teeth.
3. Remove the oil pump pinion securing nut and lockwasher, then slide off the primary and the oil pump gear set.
4. Remove the woodruff key from the crankshaft.

Removing the primary gear nut while holding the clutch with the factory tool

On F11 models, remove the tachometer pinion and the oil pump gear

Other Models

1. Remove the left crankcase cover.
2. F11 only: Remove the tachometer pinion and the oil pump gear.
3. Bend back the primary drive gear securing nut lockwasher.
4. Keep the primary drive gear from turning by installing the clutch holding tool (see the accompanying illustration), or stuffing a rag between the primary and clutch housing gear teeth, then remove the securing nut and lockwasher.

INSTALLATION

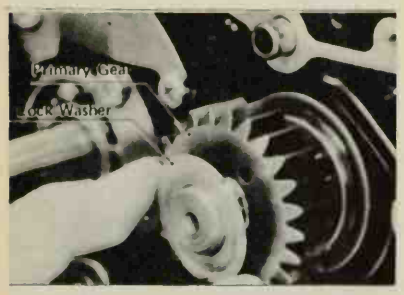
F5 and F8

Installation is a reversal of the removal procedure. Note the following:

a. Torque the oil pump pinion securing nut to 36 ft lbs;

b. Make sure to bend one side of the lockwasher up against the flat on the nut;

c. Centerpunch the lockwasher into the small hole in the oil pump pinion.



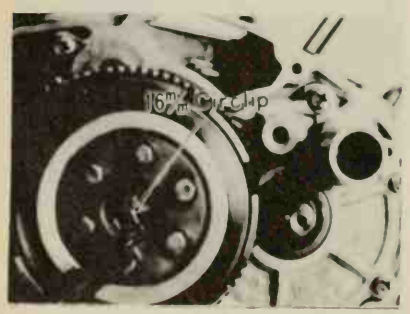
Other Models

Installation is a reversal of the removal procedure. Note the following:

a. Torque the primary gear nut to the specification given in the "Engine Torque Specifications" chart at the end of this section;

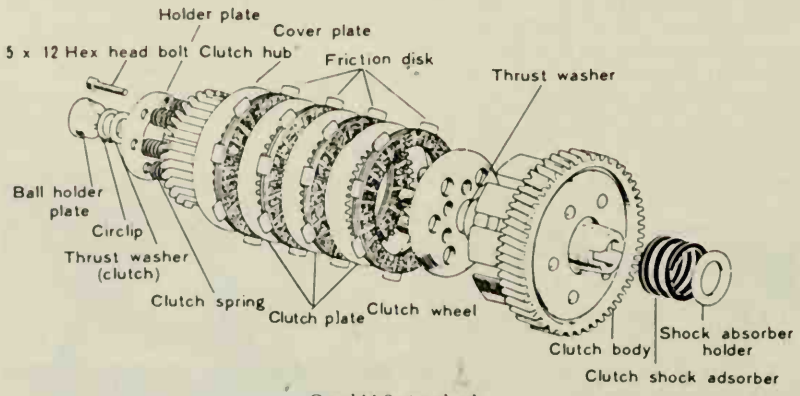
b. Make sure to bend one side of the lockwasher up against a flat on the nut;

c. F11 only: Make sure to fit the tab on the lockwasher into the hole in the primary gear.



On F11 models, be sure that the tab on the lockwasher is fitted in the hole in the primary gear

Clutch

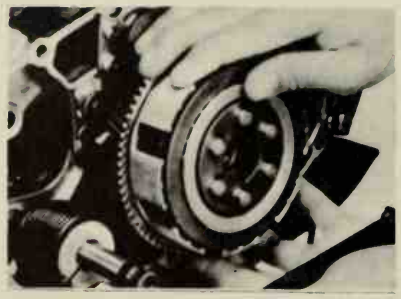


REMOVAL

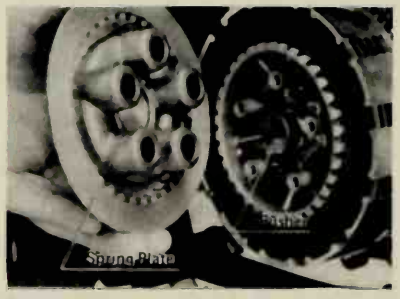
G and M Series

1. Remove the right-crankcase cover as described previously.

Removing the mainshaft circlip



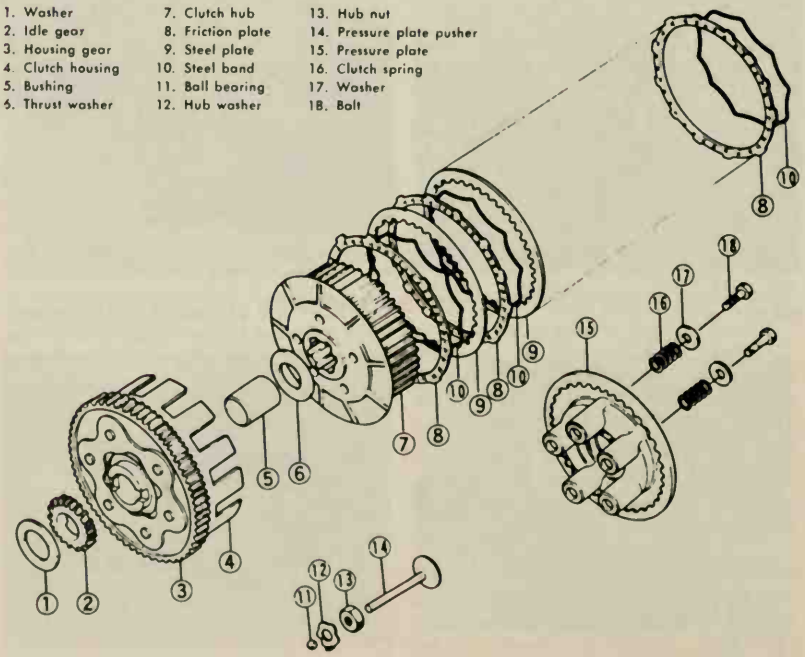
G and M Series clutch



2. Remove the clutch spring plate disc from the center of the clutch hub.
3. Remove the circlip from the transmission mainshaft in the center of the clutch hub. Remove the thrust washer from behind the circlip.
4. Remove the clutch plate assembly from the clutch hub, and the thrust washer located behind the clutch plate assembly on the mainshaft.
5. Remove the clutch housing, housing spring, and thrust washer from the mainshaft.
6. To disassemble the clutch plate assembly, remove the six clutch spring bolts from the outer plate. Remove the outer plate and the six springs. The steel plates, friction plates, pressure plate, and clutch hub can now be separated.

F and KS Series

1. Remove the left crankcase cover.



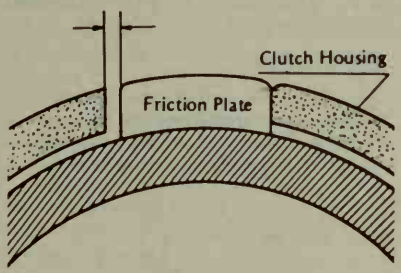
Removing the clutch plate assembly

Remove the pressure (spring) plate and the pressure plate pusher

1. Washer
2. Idle gear
3. Housing gear
4. Clutch housing
5. Bushing
6. Thrust washer
7. Clutch hub
8. Friction plate
9. Steel plate
10. Steel band
11. Ball bearing
12. Hub washer
13. Hub nut
14. Pressure plate pusher
15. Pressure plate
16. Clutch spring
17. Washer
18. Bolt

F and KS Series clutch

2. Unscrew the five retaining bolts, then pull out the clutch springs and spring guides.
3. Remove the pressure plate, friction plates, steel plates, and steel rings.
4. Pull out the pressure plate pusher.
5. Hold the clutch housing secure with the special tool illustrated or by stuffing a rag between the primary and clutch gear teeth.
6. Remove the hub securing nut and thrust washer, then slide off the clutch hub and housing.
7. Remove the clutch bushing and thrust washer from the shaft.



Remove the clutch hub securing nut while holding the clutch housing with the factory tool

INSPECTION

All Models

1. Refer to the "Engine Specifications" chart at the end of this section for individual model specifications.
2. If any plate is warped more than 0.1 mm (0.004 in.), all the plates should be replaced.
3. Check the condition of the steel bands (if fitted), and replace any which are damaged.

If the clearance between the clutch housing and the friction plates is excessive, the defective parts will have to be replaced

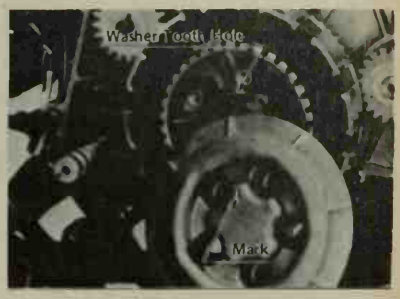
4. Measure the clearance between the clutch housing and the tabs on the friction plates. If the clearance is greater than the service limit, replace the housing and/or the friction plates.
5. Remove the bushing from the housing (if fitted), and inspect both the inner and outer surfaces for scoring, scratches, or wear. Remove any such imperfections with emery cloth or sandpaper. If the damage cannot be remedied in this way, replace the bushing.
6. Insert the bushing into the housing and check for play. If the clearance is excessive, replace the bushing. If a new bushing yields an excess of play, replace the housing.
7. Place the bushing on the mainshaft. If excessive play is noted here, the bushing should be replaced.

A worn or scored bushing will cause excessive clutch noise and possibly impair operation.

INSTALLATION

G and M Series

1. Clean all metal parts in a solvent. Lubricate them with transmission oil before assembly.
2. Assemble the clutch plates onto the hub. The first plate to be installed is a steel plate. On G series, the first steel plate is slightly different from the others Install a friction plate, steel plate, and so on.
3. Install the pressure plate over the last friction plate. Install the clutch outer plate, clutch springs, and clutch spring bolts.
4. Install a thrust washer, and clutch housing spring on the mainshaft. Install the clutch housing. Install a thrust washer and then the clutch plate assembly into the clutch housing.
5. Install the third thrust washer onto the mainshaft, then secure the clutch assembly in place with a circlip.
6. The remainder of installation is the reversal of the removal procedure. When installation is complete, adjust the clutch as described in "Maintenance."



F and KS Series

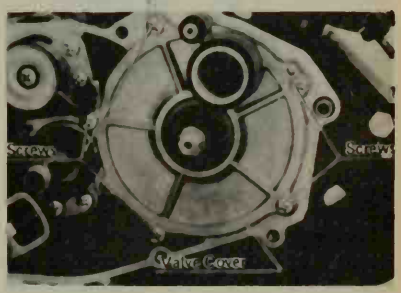
1. Clean all metal parts in a solvent. Lubricate them with clean transmission oil before assembly.
2. Install the thrust washer and kick pinion gear onto the mainshaft if they were removed.
3. Install the bushing into the clutch housing if it was removed and fit the clutch housing onto the mainshaft. Install the clutch hub thrust washer.
4. Install the clutch hub onto the mainshaft. Install the lockwasher. On KS125 models, the tab on the washer must fit into the hole in the hub. Install a friction plate, steel band (if fitted), steel plate, friction plate, and so on.

Installing the hub washer. On KS125 models, be sure that the tab on the washer is fitted into the hole in the clutch hub.

5. Install the pressure plate, spring guides (if fitted) springs, washers, and the spring bolts. On KS125 models, the mark on the pressure plate must align with the washer tooth hole. Tighten the spring bolts evenly and gradually so as not to warp the pressure plate.

On KS125 models, the mark on the pressure plate must align with the washer tooth hole

6. The remainder of installation is the reversal of the removal procedure. When installation is complete, adjust the clutch as described in "Maintenance."



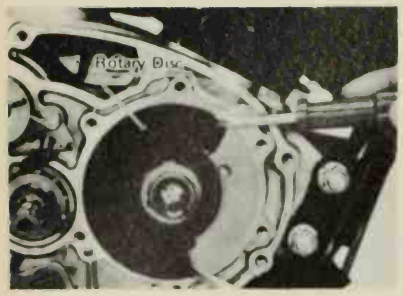
Rotary Valve Assembly

The rotary valve is mounted directly to the end of the crankshaft and rotates within a sealed disc cover. The rotary valve can move back and forth on the crankshaft so that when the piston is on its downstroke, the increased pressure in the crankcase pushes the valve against the disc cover to form a tight seal, thus preventing a loss of crankcase pressure necessary to force the fuel mixture through the transfer ports to the combusion chamber.

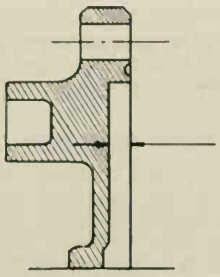
On all models but the KS125, F8, and F5, the disc is made from phenol resin. The KS125, F8, and F5 models are equipped with a steel disc.

REMOVAL

1. Remove the right crankcase cover, primary gear, and clutch.
2. Remove the valve cover screws using an impact driver. Break each screw loose, and when all of them are loose, remove them.
3. Remove the valve cover.
4. Slide the rotary disc off the end of the crankshaft. If the disc must be pried off the crankshaft, use two wedges spaced 180° apart so as not to deform the disc.



Remove the valve cover screws and the valve cover

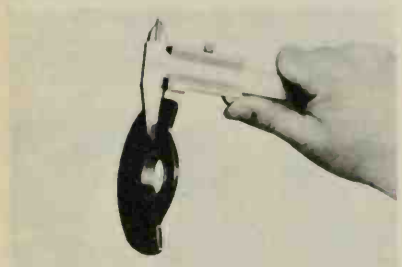


5. Remove the sleeve and O-ring from the crankshaft (if fitted).
6. Remove the locating dowel pin or woodruff key from the crankshaft.

INSPECTION

1. Inspect the valve cover oil seal. The seal should be replaced if the lips are

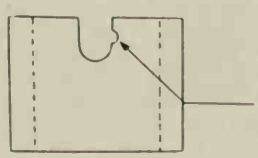
Removing the rotary disc



Measure the depth of the valve cover at the point shown

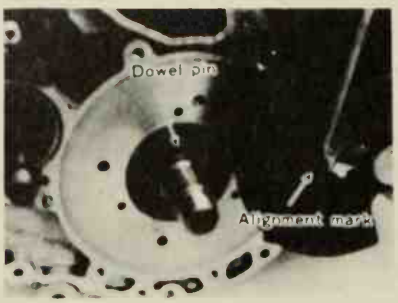
torn, deformed, hardened, or otherwise damaged.

2. Inspect the condition of the oil seals. If the oil seals are deformed in any way they should be replaced. If the large O-ring does not fit properly in its groove, it should be replaced.

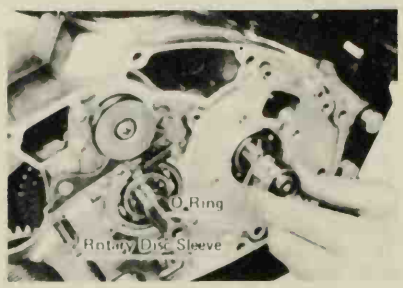


3. Examine the valve cover for any deep scratches, excessive wear, or distortion. Also measure the depth of the cover and replace it if it is beyond the service limit.

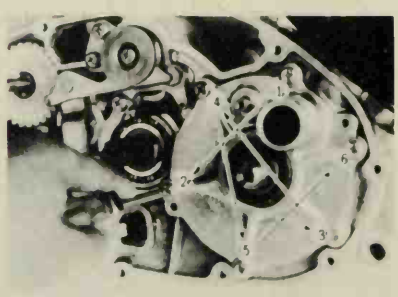
4. Inspect the rotary disc for scratches, distortion, or any other signs of damage. Also measure the thickness of the rotary disc and replace it if worn beyond the service limit.



Measuring the thickness of the rotary disc



5. Inspect the groove in the valve disc hub. If a groove is worn in it from contact with the locating pin, the disc should be replaced. Also inspect the locating pin and replace it if it shows signs of wear.



Check the disc collar for step-wear caused by the locating pin

On F6 and F7 models, align the mark on the disc with the dowel pin

The O-ring should fit into the sleeve (MC1)

Rotary valve cover tightening sequence

INSTALLATION

Installation is in the reverse order of removal. Note the following points:

1. Apply a coat of two-stroke oil to both sides of the valve disc before installation.

2. On F6 and F7 models, make sure that you align the valve disc mark with the locating dowel pin.

3. The O-ring on the crankshaft (if fitted), should fit into the sleeve.

4. Tighten the valve cover screws, a little at a time, in the order shown.

Shifter Mechanism

REMOVAL

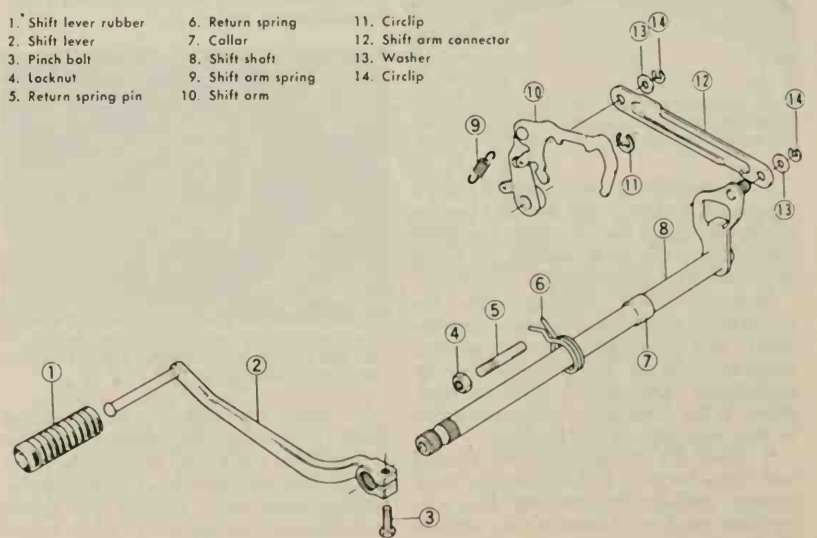
1. Remove the gearshift lever from the gearshift shaft. Mark the position of the gearshift lever in relation to the gearshift shaft before removing it so that it can be installed in the same position.

2. Remove the right crankcase cover and clutch. On F11 models, remove the 8 mm circlip from the bottom shift linkage.

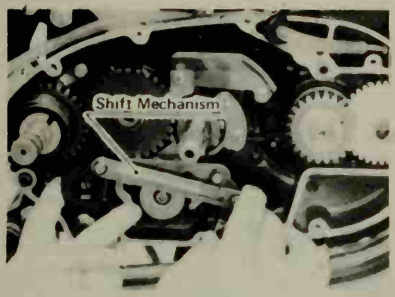
3. Disengage the shift arm from the shift drum, and pull the shift arm and gearshift shaft out as an assembly.

4. On some models the shift arm can be removed from the gearshift shaft by removing the securing circlip.

5. Remove the shift drum set lever and positioning plate along with their springs from the crankcase by removing the attaching screws.

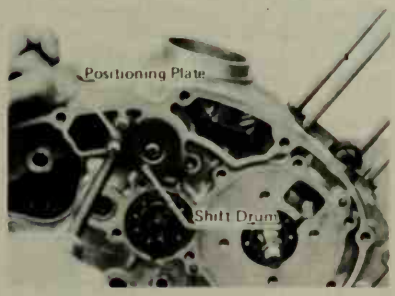


On F11 models, remove the 8 mm circlip before removing the shift shaft



INSPECTION

1. Check the splines on the gearshift shaft for wear or splintering, and replace the shaft if they are too badly damaged to properly secure the gearshift lever.



1. Shift lever rubber
2. Shift lever
3. Pinch bolt
4. Locknut
5. Return spring pin

11. Circlip
12. Shift arm connector
13. Washer
14. Circlip

Shifter mechanism—F11

Removing the shift mechanism (F11 shown)

Removing the positioning plate (MC1 shown)

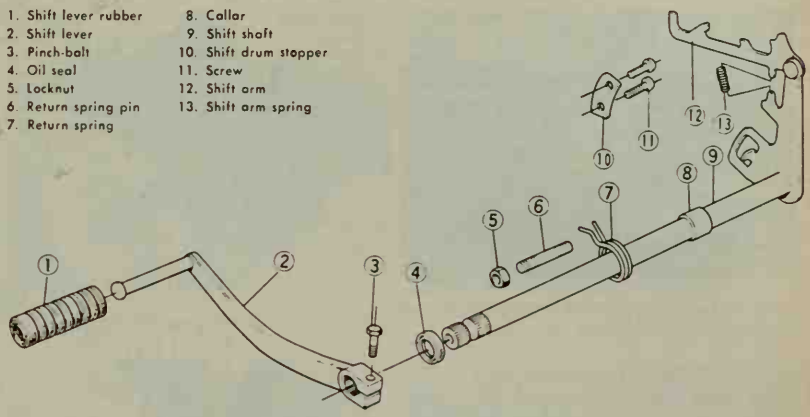
2. Check the gearshift shaft for a bent condition, and replace it if bent.

3. Check the shift arm for straightness. Check the fingers on the shift arm for straightness, and especially for wear at the tips.

4. Inspect the shifter return spring and replace it if broken, or if the ends of the spring show signs of twisting or fatigue.

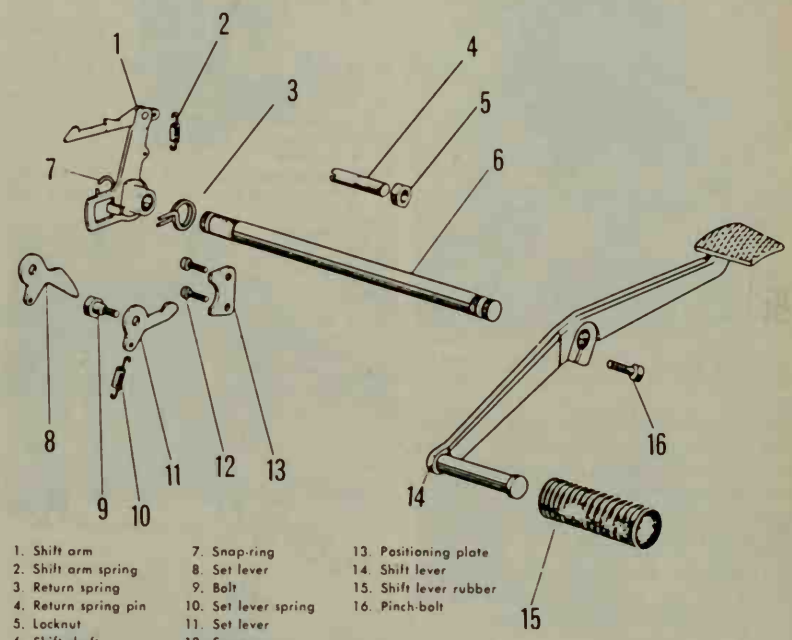
5. Check the other springs in the shift linkage and replace any which are deformed or damaged.

INSTALLATION



Installation is a reversal of the removal procedure. Note the following:

1. On F Series models (except F11), the return spring pin is an eccentric shaft. The pin should be positioned by turning it with a screwdriver so that it is centered in the window in the shift arm.



2. Make sure that each spring is installed correctly. Check the operation of the shifter before installing the right crankcase cover.

Kick-Starter Assembly

The kick-starter assembly of the F11 and KS125 models can be removed with the engine in the frame. For service to the kick-starter assembly on other models, refer to the following section on "Lower End and Transmission."

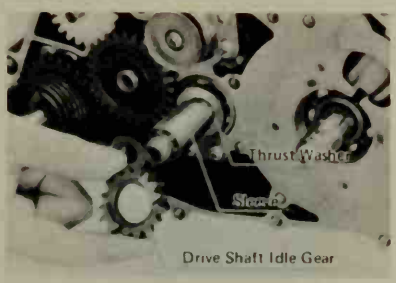
Shifter mechanism—KS and M Series

Shifter mechanism—G and F Series

REMOVAL AND DISASSEMBLY

1. Remove the right crankcase cover and clutch assembly.

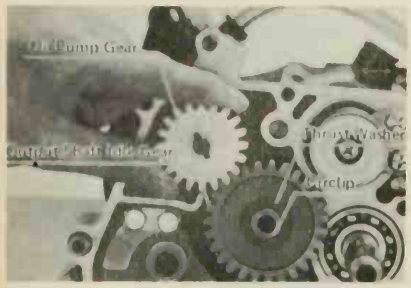
2. Remove the driveshaft idle gear from the driveshaft behind the clutch housing.



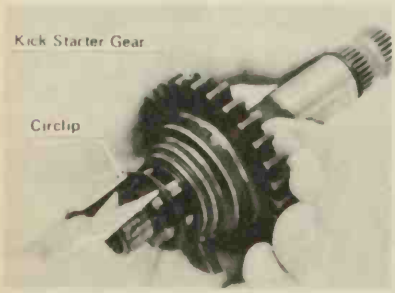
3. Unhook the kick-starter spring from the stopper pin (KS125), or from the hole in the crankcase (F11).

4. Pull the kick-starter shaft from the crankcase. On KS125 models, be careful not to misplace the thrust washer from the end of the kick-starter shaft.

5. Remove the circlip and thrust washer from the end of the output shaft, and pull the output shaft idle gear off the



Adjust the return spring pin so that it is centered in the shift arm window (F Series except F11)



Remove the driveshaft idle gear (KS125 shown)

Remove the circlip and thrust washer, then lift off the idle gear (KS125 shown)

Removing the circlip from the end of the kick-starter shaft

shaft. Take care that the thrust washer behind the gear is not misplaced.

6. KS125: Remove the oil pump gear.

7. To disassemble the components on the kick-starter shaft, first remove the spring guide and return spring from the shaft.

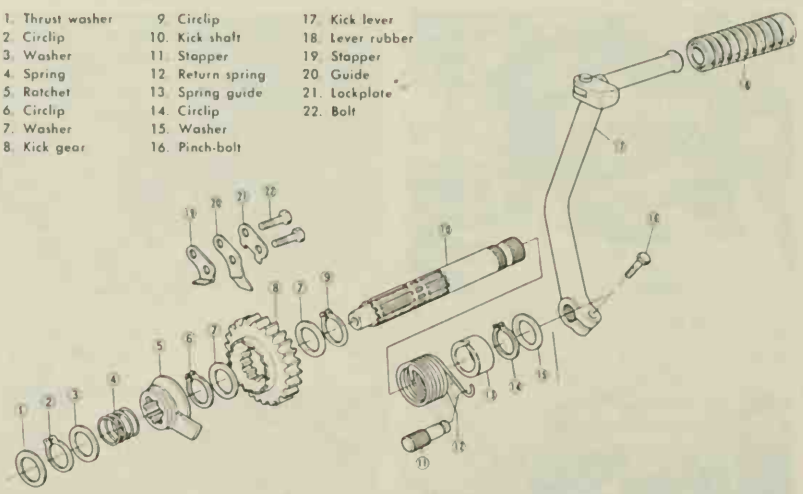
8. Remove the circlip from the other end of the shaft. Remove the spring, ratchet, circlip, washer, kick-starter gear, and washer in that order.

INSPECTION

1. Inspect the ends of the return spring. If the ends are broken or deformed or if the spring is weakened, it should be replaced.

2. Inspect the teeth on the ratchet, and the corresponding teeth on the kick-starter gear. If the teeth are worn or damaged, replace both the ratchet and the gear.

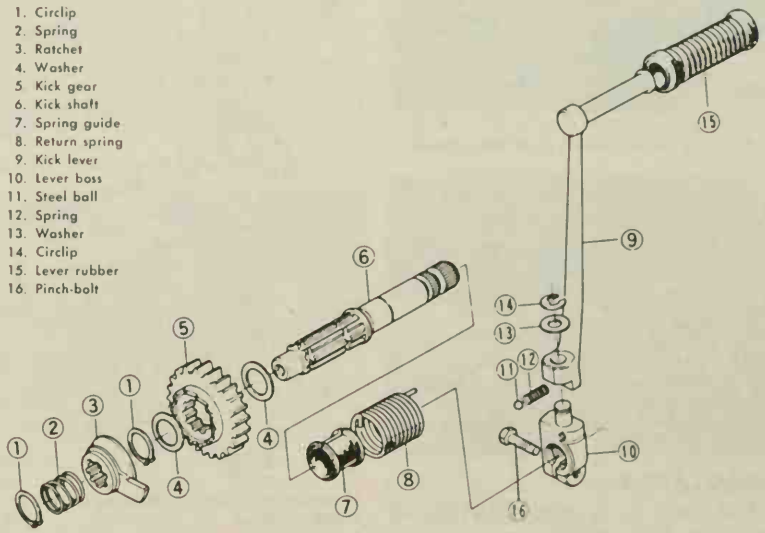
3. Measure the inside diameter of the kick-starter gear. If the measured value is less than the service limit given in the "Engine Specifications" chart at the end of this section, the gear should be replaced.



4. Measure the outside diameter of the kick-starter shaft. If the measured value is less than the service limit, the shaft should be replaced.

5. Inspect the teeth on the kick-starter gear and the other gears with which it meshes. If any of the gears are damaged, all of the gears should be replaced. Pay special attention to the oil pump gear on KS125 models.

ASSEMBLY AND INSTALLATION



1. Assemble the components onto the kick-starter shaft in the reverse order of disassembly. Note that the ratchet must be positioned on the shaft so that the

Position the ratchet on the shaft so that the punch marks align—KS125

Install the kick-starter shaft with the ratchet facing the rear. Be sure that the thrust washer is in place on the end of the shaft.

On F11 models, install the ratchet as shown

punch marks on the shaft and the ratchet align (KS125), or so that the machined surface of the ratchet is aligned with the small depression on the shaft (F11).

2. Install the kick-starter assembly into the crankcase with the ratchet facing the rear. Insert the return spring into the kick-starter shaft, then wrap it around and fasten it to the crankcase.

3. Install the idle gears into their positions. Install the clutch and the right crankcase cover.

LOWER END AND TRANSMISSION

The following section deals with service to the crankshaft, transmission, shifter drum assembly, kick-starter assembly, crankcase bearings, and seals. Removing the engine and splitting the crankcases is necessary to service these components.

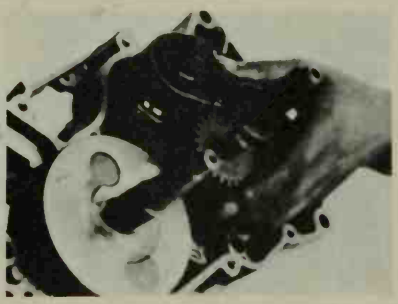
NOTE: *New gaskets must always be used when the engine is serviced.*

Splitting The Crankcases

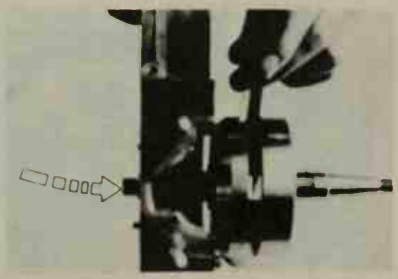
Before splitting the crankcases it is necessary to remove the top end, left and right crankcase covers, clutch assembly, primary drive gear, magneto, countershaft sprocket, shifter mechanism, kick-starter (F11 and KS125), rotary valve (if fitted), etc. The removal procedures for these components are given in the preceding sections. The following sections assume that these components have been removed.

G AND F SERIES (EXCEPT F11)

1. Remove the transmission neutral switch body and set plate.
2. On F5 and F8 models, remove the circlips on the ends of the Fourth and Fifth gearshift rods.



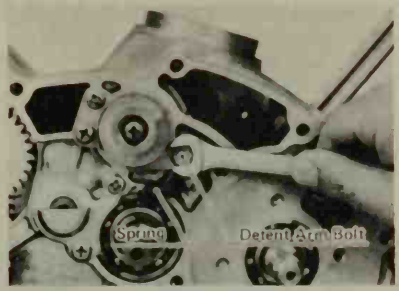
Removing the transmission switch body



3. Remove the crankcase halves' securing screws.
4. Split the cases by tapping each half alternately with a mallet or plastic hammer. Leave the transmission and all shafts in the right case.

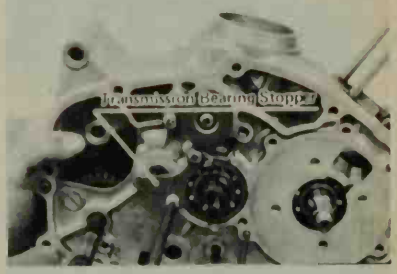
CAUTION: *Never strike the end of the crankshaft to split the cases as the crankshaft may become bent in the attempt.*

5. Tap the end of the transmission drive shaft lightly with a mallet, then remove the change drum and transmission as a complete assembly.
6. On the G Series, remove the kick-starter spring and holder from the right case half, then remove the kick-starter gear and shaft together.
7. On the F Series, remove the retaining snap-ring, return spring and holder from the right case, then pull out the kick-starter shaft and gear together.
8. Remove the dowel pin from the right end of the crankshaft. Insert a soft metal (copper or brass) wedge between the flywheels opposite the crankpin to avoid pinching the flywheels and tap the crankshaft out of the case with a plastic mallet.
9. Remove the main bearing retainers, pry out the oil seals, and then remove the bearings with an arbor press, or by heating the cases and tapping out the bearings.

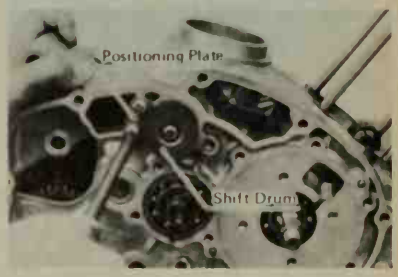


Remove the transmission as a unit

After removing the dowel pin, tap the crankshaft with a plastic mallet to remove it



Transmission driveshaft bushing



Removing the detent arm bolt

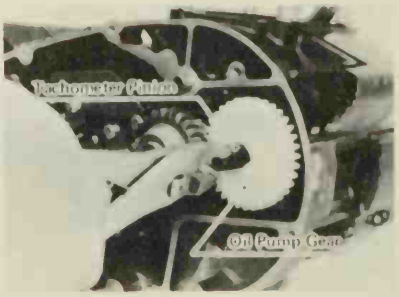
M SERIES

1. Remove the kick-starter spring guide and spring from the kick-starter shaft.
2. Remove the detent arm bolt and detent arm spring from the shift drum detent arm. Remove the detent arm.
3. Remove the transmission bearing stopper. Remove the two phillips head screws from the shift drum positioning plate and remove the positioning plate.
4. Using an impact driver remove the 13 screws which secure the cases together.
5. Fit the crankcase separating jig (Tool No. 57001-153) to the left case half, and tighten the jig bolt, while tapping lightly on the end of the transmission countershaft with a plastic mallet. Separate the cases gradually and evenly.
6. The crankshaft and transmission components will remain in the right case half.
7. Remove the kick-starter shaft complete with kick-starter gear.
8. Remove the transmission and shift drum as an assembly. Take care not to lose the ball bearing fitted at the end of the mainshaft.

Removing the transmission bearing stopper

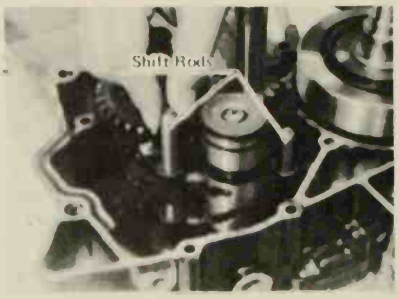
Removing the positioning plate

Crankcase separating jig installed

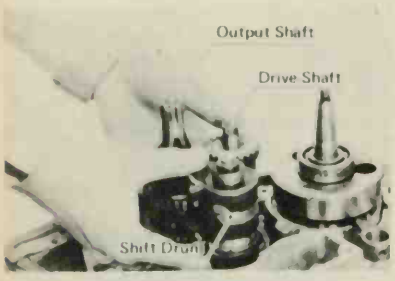


9. Using a plastic mallet, tap the crankshaft from the right case half.
10. Remove the main bearings from the ends of the crankshaft using a bearing puller.

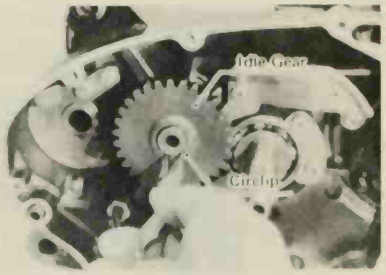
F11



1. Remove the bearing holder from the left case half.
2. Pull the tachometer pinion and oil

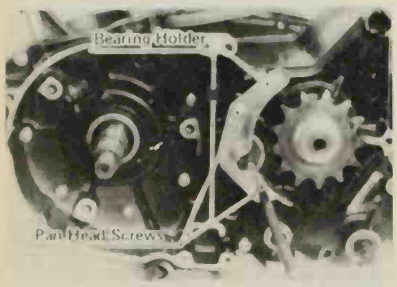


Removing the kick-starter shaft and gear

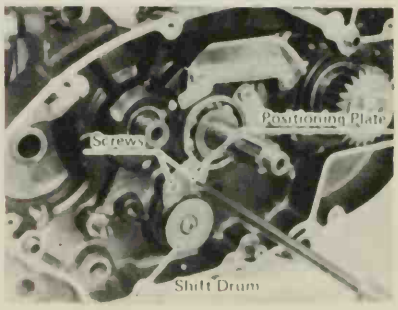


Pull out the tachometer pinion and oil pump gear

Removing the shift rods



Remove the transmission as a unit



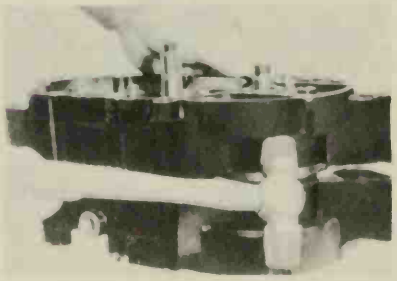
Remove the circlip and lift off the kick-starter idle gear

Removing the Fourth and Fifth gearshift forks

Removing the bearing holder

Removing the shift drum positioning plate

While holding back the Third gearshift fork, remove the shift drum



pump gear from the right case half. Note the location of any thrust washers.

3. Remove the circlip and thrust washer from the idle shift and lift off the kick-starter idle gear.

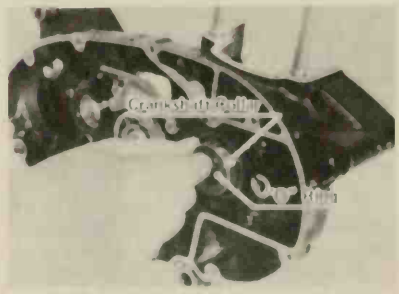
4. Remove the two screws from the shift drum positioning plate and remove the positioning plate.

5. Remove the neutral positioning bolt, spring, and positioning pin from the bottom of the left case half.

6. Remove the 11 crankcase securing screws with an impact driver. Using a plastic mallet, tap evenly around the right case half until the cases are about 1/16 in. apart. Lay the engine on its left-side and continue tapping evenly around

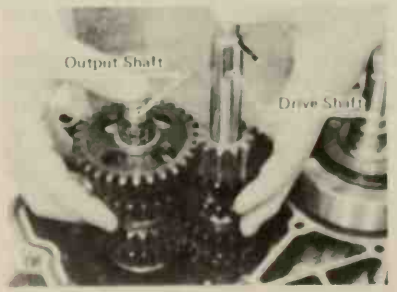
Separating the crankcases

the right case until it comes free of the crankshaft. The crankshaft and the transmission will remain in the left case half.

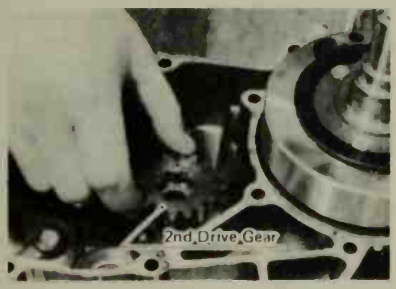


CAUTION: *Never strike the end of the crankshaft to split the cases as the crankshaft may become bent in the attempt.*

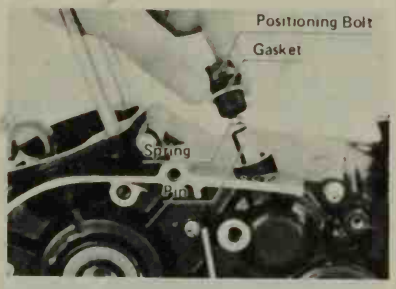
7. Remove the breather hose, crankshaft collar, and the O-ring from the right case half.



8. Remove the two shift rods and the Fourth and Fifth gearshift forks. Hold the Third gearshift fork away from the shift drum, then remove the shift drum and the Third gearshift fork. The output shaft



Remove the neutral positioning bolt, spring, and positioning pin



Remove the crankshaft collar and O-ring

The transmission shafts are removed as a unit

Lift the 2nd drive gear from the left case

Removing the positioning bolt, spring, and positioning pin

Installing the kick-starter shaft

and the driveshaft can now be removed as an assembly.

9. Remove the 2nd drive gear, thrust washer, and needle bearing from the left case.

10. Using a press, push the crankshaft out of the left case. If a press is not available, insert a soft metal (copper or brass), wedge between the flywheels opposite the connecting rod to avoid pinching the flywheels, and tap the crankshaft out of the case with a plastic mallet.

11. Using a bearing puller, remove the main bearing from the left end of the crankshaft.

KS125

1. Remove the shift drum stopper and the bearing stopper from the right case half.

2. Remove the neutral positioning bolt, spring, and positioning pin from the top of the left case half.

3. Remove the steel ball from the right end of the driveshaft.

4. Using an impact driver, remove the 12 screws which secure the cases together.

5. Fit the crankcase separating jig (Tool No. 57001-153) to the left case half, and tighten the jig bolt, while tapping lightly on the end of the transmission countershaft with a plastic mallet. Separate the cases gradually and evenly.

6. The crankshaft and transmission components will remain in the right case half.

7. Lift out the two shift rods, and remove the shift forks, shift drum, and the output shaft and the driveshaft assemblies.

8. Remove the washers from the end of the driveshaft and the oil pump shaft and the two knock pins from the case half, and set them aside so that they will not be misplaced.

9. Remove the output shaft sleeve and O-ring from the left case half.

10. Using a press, push the crankshaft out of the left case. If a press is not available, insert a soft metal (copper or brass), wedge between the flywheels opposite the connecting rod to avoid pinching the flywheels, and tap the crankshaft out of the case with a plastic mallet.

11. Using a bearing puller, remove the main bearing from the left end of the crankshaft.

The crankcase splitting tool installed

ASSEMBLY

G AND F SERIES (EXCEPT F11)

1. Coat all parts with oil before installing them.

2. Using a press or a bearing driver, drive the crankshaft bearings into place. The bearings should be flush with the inside surface of the crankcase. Coat the lips of the oil seals with grease, and install them with the marked surface facing out.

3. With a plastic mallet, tap the crankshaft into the right main bearing using a soft metal wedge between the flywheels as on removal.

4. Install the kick-starter shaft.

5. Install the transmission as an assembly.

Install the transmission as a unit

6. Apply a liquid gasket compound such as Kawasaki Bond to the mating surface of the left case half. Set the right case half in position and tap it evenly around the edges until it is seated.

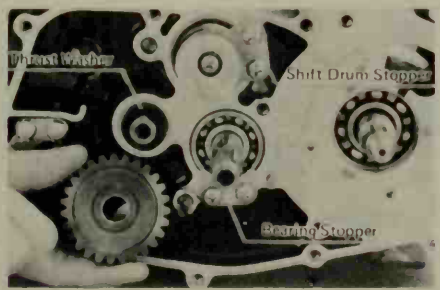
NOTE: *On the G Series, do not forget the ball and shim at the tip of the transmission driveshaft.*

7. Install the crankcase securing screws and tighten them evenly in an "X" pattern until they are all tight.

8. The remainder of assembly is in the reverse order of disassembly.

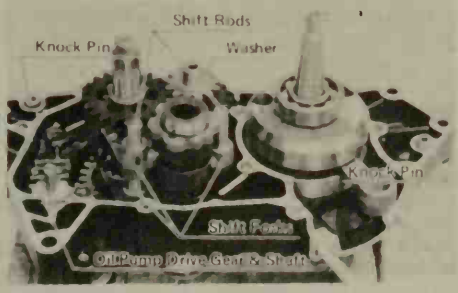
M SERIES

1. Coat all parts with clean transmission oil before installing them.



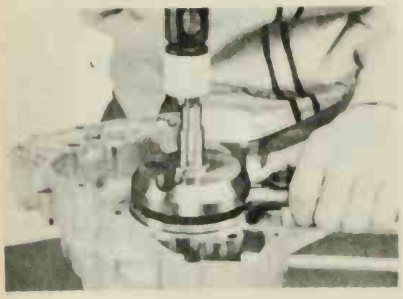
2. Install the bearings into the cases using a press.

3. Install a soft metal wedge between the crankshaft flywheels opposite the connecting rod, and tap the crankshaft into the left main bearing.

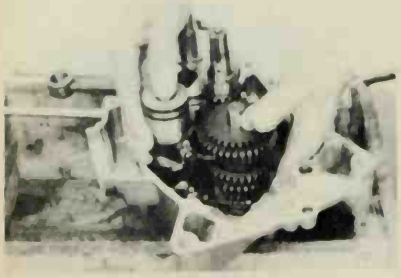


4. Fill the left end of the driveshaft with grease, and install the ball bearing into the grease. Fit the transmission components together, and install them as an assembly into the left case half.

5. Install the kick-starter shaft into the left case half.



6. Apply a coat of liquid gasket compound such as Kawasaki Bond to the mat-



Remove the shift drum stopper and the bearing stopper

Crankcase components

Tapping the crankshaft into the left main bearing

Fit the transmission components together and install the transmission as a unit

Tapping the crankcases together

ing surface of the left case half. Fit the right case into position and tap the edges of the case until it mates with the left case. Install the crankcase securing screws and tighten them gradually and evenly in an "X" pattern until all of them are tight.

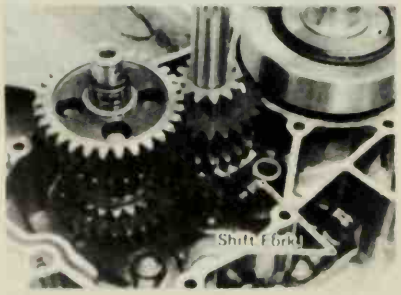
7. Center the crankshaft in the cases by tapping the end with a plastic mallet. Be sure that the crankshaft rotates freely.

8. The remainder of assembly is in the reverse order of disassembly. Note the following:

a. The detent bolt should be tightened fully into place;

b. Turn the kick-starter shaft all the way clockwise before installing the return spring.

F11



1. Coat all parts with clean transmission oil before installing them.

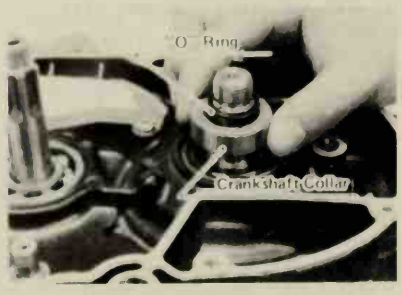
2. Install the main bearings into the case halves with a press.

3. Install the 2nd drive gear, thrust washer, and needle bearing onto the left end of the driveshaft.

4. Install the driveshaft and the output shaft as an assembly. Be careful that the gear, thrust washer, and needle bearing remain in place as the shafts are inserted into the left case.

5. Install the Third gearshift fork into place. Install the shift drum locating the shift fork pin into the groove in the shift drum. Install a shift rod into the shift fork.

3rd gearshift fork installed



6. Install the two remaining shift forks into place on the Fourth and Fifth gears and insert the remaining shift rod.

NOTE: *The wider finished surface of the shift forks must face the gear surface.*

7. Rotate the shift drum to the Neutral position and install the neutral positioning bolt, spring, and positioning pin. Torque the positioning bolt to 44–57 ft lbs.

8. Install the breather hose to the right case half.

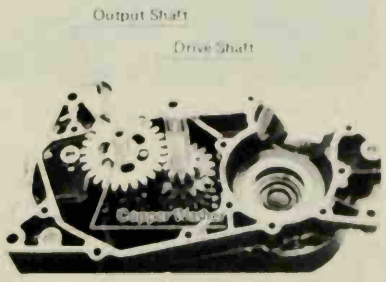
9. Apply a coat of liquid gasket compound such as Kawasaki Bond to the mating surface of the left case half. Fit the right case half into position and tap the edges of the case down until it mates with the left case. Install the crankcase securing screws and tighten them gradually and evenly in an "X" pattern until all of them are tight.

Installing the crankshaft collar and O-ring

10. Install the crankshaft collar and O-ring on the right-side of the crankshaft.

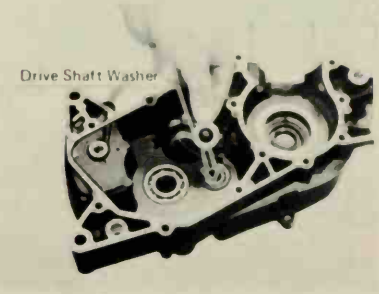
11. The remainder of assembly is in the reverse order of disassembly.

KS125



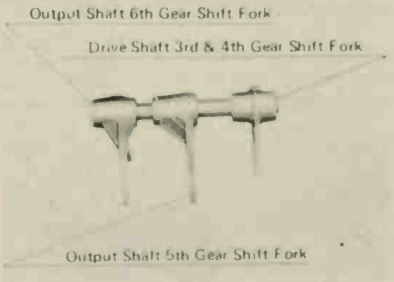
1. Coat all parts with clean transmission oil before installing them.

2. Install the two knock pins into the left case half.



3. If the crankshaft was removed, install it into the left case half using a press.

4. Install the driveshaft washer into place in the left case half. Mesh the gears of the driveshaft and the output shaft together and install the two shafts into the left case half. Install the copper washer on the end of the output shaft.

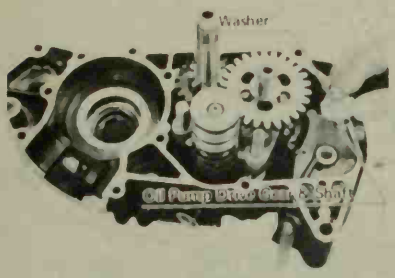


5. Install the shift forks onto their proper gears. Install the shift drum into the left case half. Fit the shift fork guide pins into the proper grooves in the shift drum.

Install the driveshaft washer into position in the left case half

Be sure that the copper washer is installed on the end of the output shaft

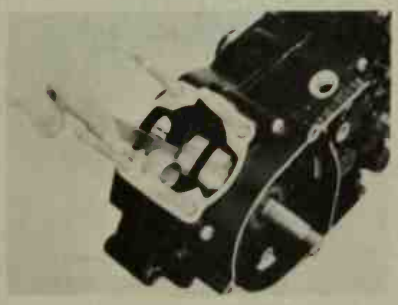
Shift forks; note the differences between the forks



6. Install the two shift rods. The longer of the two rods fits to the output shaft side.

7. Install the oil pump driveshaft and gear in the left case half, and install a washer on the shaft. Install the oil pump gear.

8. Apply a coat of liquid gasket compound such as Kawasaki Bond to the mating surface of the left case half. Fit the right case half into position, and using a press, press the two case halves together. Install the crankcase securing screws and tighten them in an "X" pattern until all of them are tight.



NOTE: *It may be necessary to rotate the oil pump drive gear so that it will mesh with the tachometer drive gear as the cases come together.*

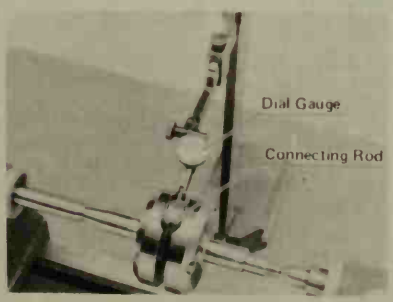
9. Using feeler gauges, measure the clearance between each of the flywheels

Installing the oil pump driveshaft and gear

and the crankcase. Tap the crankshaft on the ends with a plastic mallet, until the crankshaft is centered.

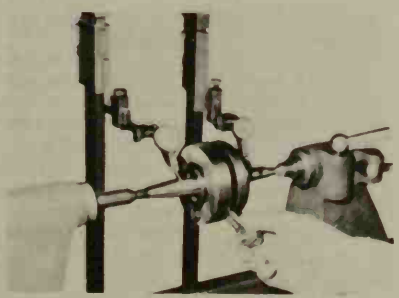
Centering the crankshaft

10. The remainder of assembly is in the reverse order of disassembly.



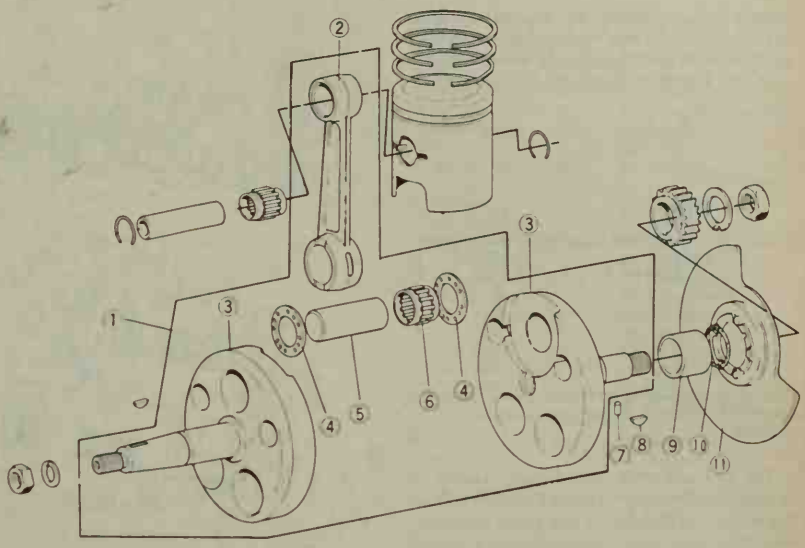
Crankshaft

1. Crankshafts on all models are pressed together. To disassemble any crankshaft (which would be necessary in the event of a bent connecting rod or worn big end bearing), a special press is needed.



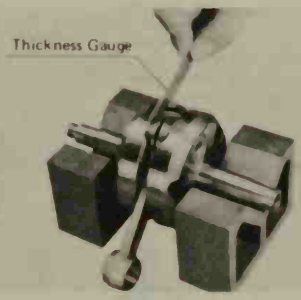
2. Lubricate the big end bearing with two-stroke oil. Rotate the rod slowly around the crankpin. The movement should be smooth and noiseless.

3. With the crankshaft mounted in a jig, and a dial indicator mounted to bear against the bottom of the connecting rod, push the con rod first toward the gauge and then away from it. The difference between the readings on the gauge is the radial clearance of the connecting rod big end. If the clearance is beyond the service limit, the crankshaft should be replaced or disassembled and inspected.



4. Check the connecting rod big end side clearance with a feeler gauge placed between the big end and one of the flywheels. If the side clearance exceeds the service limit given in the "Engine Specifications" chart at the end of this section, the crankshaft should be replaced or disassembled and inspected.

Checking the big end radial clearance



Checking the amount of crankshaft run-out

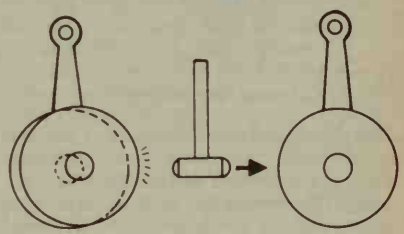
4. Washer
5. Crankpin
6. Big end bearing
7. Locating pin
8. Woodruff key
9. Collar
10. O-ring
11. Rotary disc



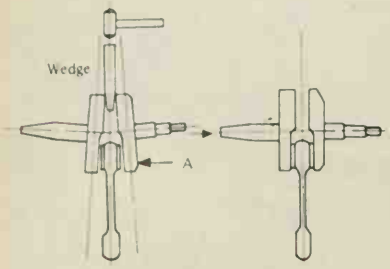
Checking the big end side clearance

5. Mount the crankshaft in a set of V-blocks, and attach dial indicators to each end of the crank.

Rotate the crank slowly and note the indicator readings. The maximum allowable run-out is 0.0039 in. (0.10 mm). If run-out exceeds this figure, the crankshaft is either bent, or the flywheels are out of alignment.

6. The following procedure concerning crankshaft truing should only be undertaken by an experienced mechanic. The information is supplied, however, for the purpose of providing general information.

7. The crankshaft must be checked for eccentricity and for parallel flywheels. The crankshaft flywheels are eccentric if one has been rotated slightly ahead of the other. The flywheels are nonparallel if they lean toward or away from each other.

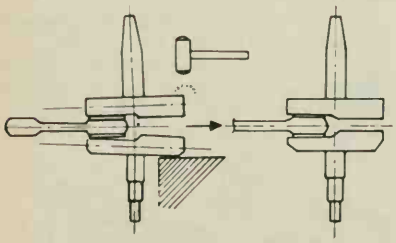


Eccentric flywheels

8. Turn the crank in the jig. If the dial gauges do not move the same distance, and do not begin and end their movement at the same time, the crankshaft flywheels are both eccentric and nonparallel. In this event, eccentricity must be taken care of first.

9. To correct eccentricity, rotate the crank until the drive-side dial gauge indicates the high point of its travel. Stop at this point. Imagine a line drawn from one of the dial gauge shafts to the other. Mark the spot on the drive-side flywheel at the spot this line would cross it. Remove the crankshaft from the aligning jig, and, with the brass hammer, strike this spot on the drive-side flywheel smartly. Be sure that you are holding the crank assembly by the magneto-side shaft while doing this. Recheck alignment, and repeat this procedure as long as necessary until the dial gauge needles begin and end their travel at the same time.

10. Replace the crankshaft assembly in the jig, and rotate it until the needles reach their highest point of travel. If the



crankpin lies along an imaginary line drawn between the ends of the two dial gauge shafts, the flywheels are evidently pinched together opposite the crankpin.

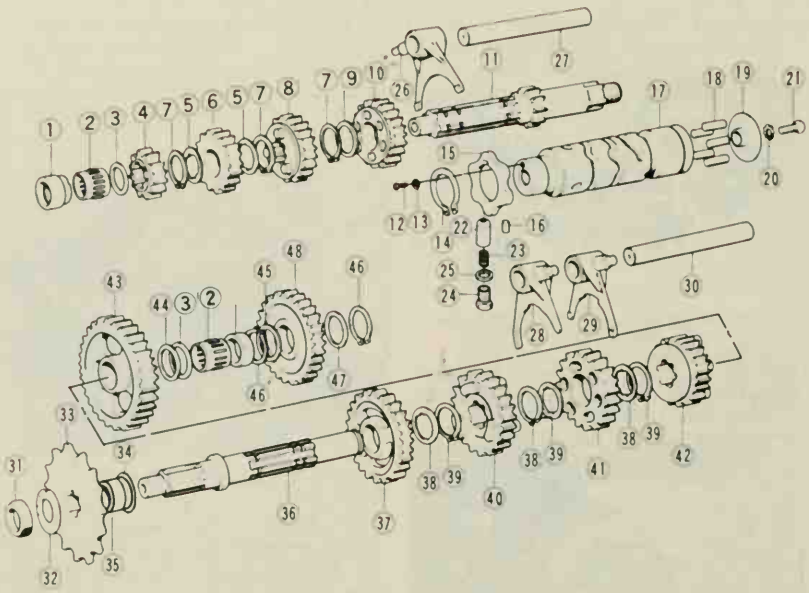
Correcting nonparallel flywheels. Never strike the flywheels at point A or the side clearance will be reduced.

To correct this condition, insert a wedge, preferably of wood or soft metal, between the flywheels at a point opposite the crankpin, and, supporting the crank in one hand, strike the wedge with a hammer to spread the flywheels apart. Continue until the flywheels are parallel within specifications.

11. If, when checking for parallelism, the crankpin was *not* along or near the

Correcting nonparallel flywheels

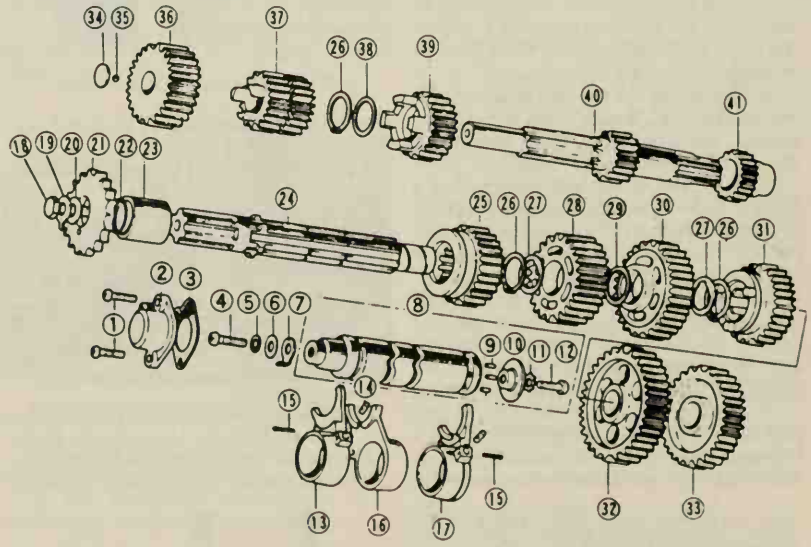
line drawn between the ends of the dial gauge shafts, if it was opposite this line, then the flywheels are too far apart, opposite the crankpin. In this case, once again make a mark on either flywheel where the imaginary line would cross it. (Note that the crank should be positioned so that the dial gauges are at the highest point of their travel). Remove the crank, and, with the brass hammer, strike the flywheel sharply on the *side* to bring the flywheels closer together. Check again, and repeat the procedure until crank runout is within specification.



12. Clean the crank assembly thoroughly, and oil the big end bearing well.

Transmission

1. The gears should not be removed from their shafts unless absolutely necessary. If the gears are being removed, be sure that each gear, thrust washer, shim, and snap-ring is laid out in the order of removal so that it can be installed in the proper location.



NOTE: *When referring to the exploded diagrams, note that the number of thrust washers may vary for individual machines.*

2. Check each of the gears for chipped, broken, or worn teeth. If any gear shows evidence of such damage, it should be re-

KS125 transmission assembly

G Series transmission assembly

placed. In addition, the gear with which it meshes should be replaced as well, since it has undoubtedly been overstressed.

3. Check the inner splines on those gears so equipped, and replace the gear if the splines are worn or broken. Inspect the corresponding splines on the shafts. The shafts should be replaced if damaged.

4. Inspect the engaging dogs on gears which have them. The dogs must not be worn, chipped, or broken. Replace the gear if they are.

5. Inspect the transmission shafts for damage to the sprocket nut threads, and wear or damage to the clutch gear, or sprocket splines. Make sure that the shafts are not bent. Inspect the shaft bearings (see below).

6. Where applicable, check the transmission gears for smooth rotation on their shafts. If rotation is rough or noisy, replace the gear needle bearing (where fitted) or the gear itself.

Shift Drum

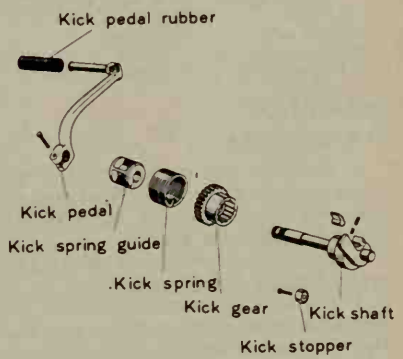
1. The shift drum itself should be inspected for wear in the shift fork cam follower pin grooves, wear to the cam plate, and scoring or wear of the bearing surfaces.

2. The shift fork shafts should be inspected for wear in those areas on which the shift forks ride. Roll the shafts along a flat surface to check them for a bent condition. Replace the shafts if bent.

3. Check the shift forks themselves. Note any wear to the fork bore. Check the fingers for bends, or for chipping or wear. Replace any fork on which such defects are noted.

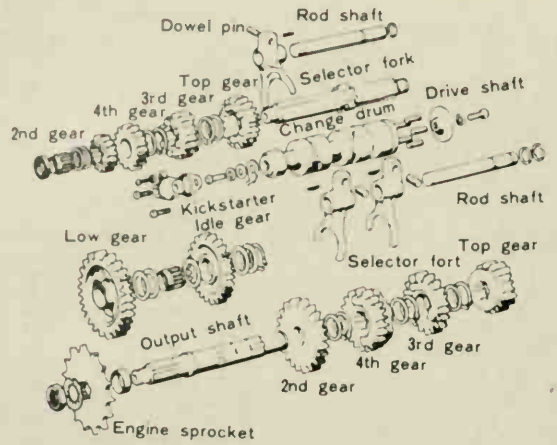
4. Check the shift fork cam follower pins for wear, and replace them if damaged.

5. Check the shift drum dowl pins. Replace any broken, worn or missing pins.



Kick-Starter

DISASSEMBLY



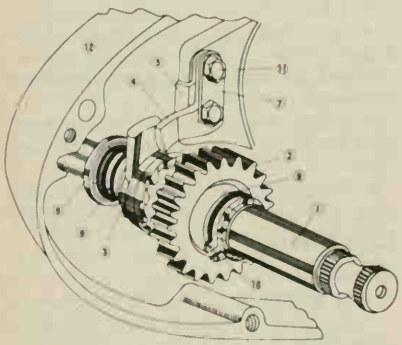
G and M Series

1. Remove the gear from the kick-starter shaft.

2. Separate the gear, shaft, pawl push pin, pawl, and spring.

G Series kick-starter assembly

F Series transmission assembly



3. Remove the kick-starter stopper from the left case.

F6 and F7

1. Remove the spring guide and spring.
2. Remove the two retaining circlips.
3. Separate all parts.

F8 and F5

1. Remove the kick-starter gear snap-ring, then separate the gear from the shaft.
2. Leaving the kick-starter shaft in the case, remove the ratchet, spring holder plate, and spring from the shaft.

F5 and F8 kick-starter assembly

1. Kick-starter shaft
2. Kick-starter gear
3. Ratchet
4. Kick guide
5. Kick stopper
6. Spring holder
7. Lockplate
8. Return spring
9. Washer
10. Circlip
11. Bolt
12. Right crankcase

INSPECTION

G and M Series

1. Examine the gear teeth and the inner surface in which the pawl engages the gear. If excessively worn or deformed, replace the gear.
2. Inspect the kick-starter pawl tip for wear. Replace if necessary.
3. Examine the pawl pin hole for obstructions. Also check to make sure that there is free movement of the pawl pin and spring.

F6 and F7

1. Inspect the kick-starter gear guide and splines for excessive play. Also roll the shaft on a flat surface to be sure that it is not bent.
2. Examine the gear teeth for general condition.

F8 and F5

1. Make sure the ratchet slides along the kick-starter guide freely.
2. Roll the kick-starter shaft on a flat surface to make sure that it is not bent.

ASSEMBLY

G and M Series

1. Install the kick-starter stopper in the left case.
2. Install the pawl spring and then the pawl push pin in the hole in the shaft.
3. Install the pawl, then while holding it down, install the kick-starter gear.

4. Insert the assembly in the right case.

5. Insert one end of the kick-starter spring in the case hole, then twist the spring about 120° and insert the other end in the kick-starter shaft.

6. Install the kick-starter shaft holder.

F6 and F7

1. Install the kick-starter guide and stopper on the crankcase.

2. Install the shaft in the case and secure with the two snap-rings. Install the spring holder, spring, and collar as described for the G and M Series models.

3. Align the ratchet and kick-starter shaft marks, then insert the ratchet.

4. Install the kick-starter gear and secure it with the circlips.

F8 and F5

1. Insert the shaft in the right case and secure it with the two snap-rings.

2. Insert one end of the return spring in the right case.

3. Twist the spring 120° and insert the other end in the kick-starter shaft.

4. Install the spring guide.

5. Install the kick-starter gear with holder and secure with the circlip.

Bearings and Seals

1. Bearings can be checked in place, whether on the crankshaft or still in the cases.

2. Lightly lubricate the bearing in question with some two-stroke oil, and rotate it slowly. Movement must be smooth, effortless, and quiet.

3. If the bearing movement is halting, or noisy, the bearing should be replaced.

4. Check the general condition of the bearing in place, if possible. Note any damaged bearings or scored races.

5. If the bearings must be replaced, note the following:

a. Crankshaft bearings should be replaced in sets, along with the oil seals;

b. Bearings, either crankshaft or transmission, which remain in the crankcases can be removed after taking away any bearing retainer plates, snap-rings or oil seals which are fitted;

c. Bearing removal from crankcases is facilitated by gently heating the crankcase around the bearing boss. Tap out the old bearing, and drive new ones straight in (after heating the case) with a bearing driver, or a sturdy block of wood.

6. Oil seals should be replaced as a matter of course. Oil seals can be pried out of the cases with a screwdriver using a block of wood as a leverage point. Alternately, use a hooked tool to remove the seals. Seals with damaged or torn lips must be replaced.

7. Once seals are removed, they should not be reused for any reason.

8. Upon assembly, lubricate the bearing before installation with the type of oil usually supplied to it (i.e., either transmission or two-stroke oil). Grease the lips of all oil seals before inserting any shafts into them.

9. Where applicable, all bearings and seals should be installed with the manufacturer's mark facing outward.

LUBRICATION SYSTEM

DESCRIPTION

Both Superlube and Injectolube systems include an oil reservoir, oil feed line, oil pump, and oil delivery lines. The pumps are of the plunger type and are driven by the end of the crankshaft through reduction gears. The amount of oil fed to the induction passage delivery line and crankcase drillway (Injectolube) is determined by two variables: the speed of plunger operation and the length of plunger stroke. These variables are set by the engine rpm and the degree of throttle opening, respectively. The pump effectively meters the amount of oil according to engine speed and load and, as a result, no more and no less than the required amount is consumed. The pump also houses a check valve that keeps the oil output pressure constant and seals the delivery line when the engine is not operating.

The essential difference between the Superlube and Injectolube systems is the extra lubrication to the crankshaft main bearings and large end connecting rod bearings provided by the Injectolube type. An additional output port in the oil pump leads to a drillway in the crankcase, which in turn leads to smaller passages to these critical points.

PUMP REPAIR

The factory advises against attempting to disassemble and repair the oil pump. The internal parts are machined to very exacting tolerances and it is highly unlikely that the pump can be reassembled to factory specifications. In addition to this, oil pump failure is *very* seldom due to internal malfunction.

OIL PUMP ADJUSTMENT

See "Throttle Control Cable" in "Maintenance," for adjustment procedures.

PUMP BLEEDING

The oil pump must be bled of air between the pump and check valve, and between the reservoir and pump whenever the pump is removed, the delivery lines are disconnected, or the reservoir has run dry.

1. Remove the oil pump access cover.
2. Start and run the engine at 2,000 rpm while holding the pump control lever in the fully open position.
3. Observe the output delivery line. Any air bubbles in the system should disappear quickly. If they do not, check the tightness of the input and output line banjo bolts.
4. If there are air bubbles in the reservoir oil delivery line, disconnect it at the pump and allow oil to flow through it until the bubbles are gone, then reconnect it and repeat Steps 2 and 3. The reservoir delivery line must not be disconnected while the engine is running.

Injectolube oil injection (F11 shown)

Bleeding the oil delivery line (G Series shown)

CHECKING OIL PUMP OUTPUT

The delivery output of the oil pump should be measured when the pump is suspected as the source of a problem and after the more common causes have been checked.

Needed for this operation are: a laboratory tube graduated in cubic centimeters (tenths) or ounces (hundredths), an extra oil pump output line, and a keen eye for checking the amount of output volume.

1. Cut off one end of the extra output line and slide it over the end of the graduated tube.
2. Disconnect the oil pump output line and install the measuring tube assembly in its place.
3. Supply the carburetor with a fuel/oil mixture of 20:1.
4. Start and run the engine at 2,000 rpm for three minutes while holding the pump control lever in the fully open position.
5. Check your results with the following:

Model	Output (cc/oz)
G Series	2.8/0.095
F6	4.1/0.139
F7	5.5/0.186
F8	6.0/0.203
F5	10.0/0.338
MC1	2.6/0.089
KS125	3.1/0.105

TROUBLESHOOTING

Before proceeding, first check that the oil tank has a sufficient supply of oil.

1. In the event of piston seizure or overheating not caused by component failure or incorrect timing or carburetor settings, check the oil pump cable adjustment, the quality of oil being used (poor quality oil will cause this); check that the breather hole in the oil tank cap is open or that the oil tank breather tube (if fitted) is not blocked. Check for air in the lines by bleeding the pump. Check for air or oil leaks in the lines from the tank and to the engine.
2. In the case of excessive smoking or oil consumption, check the oil pump cable adjustment. Check for leakage at banjo fittings, and cracked or broken oil lines. Make sure that the oil is of good quality.

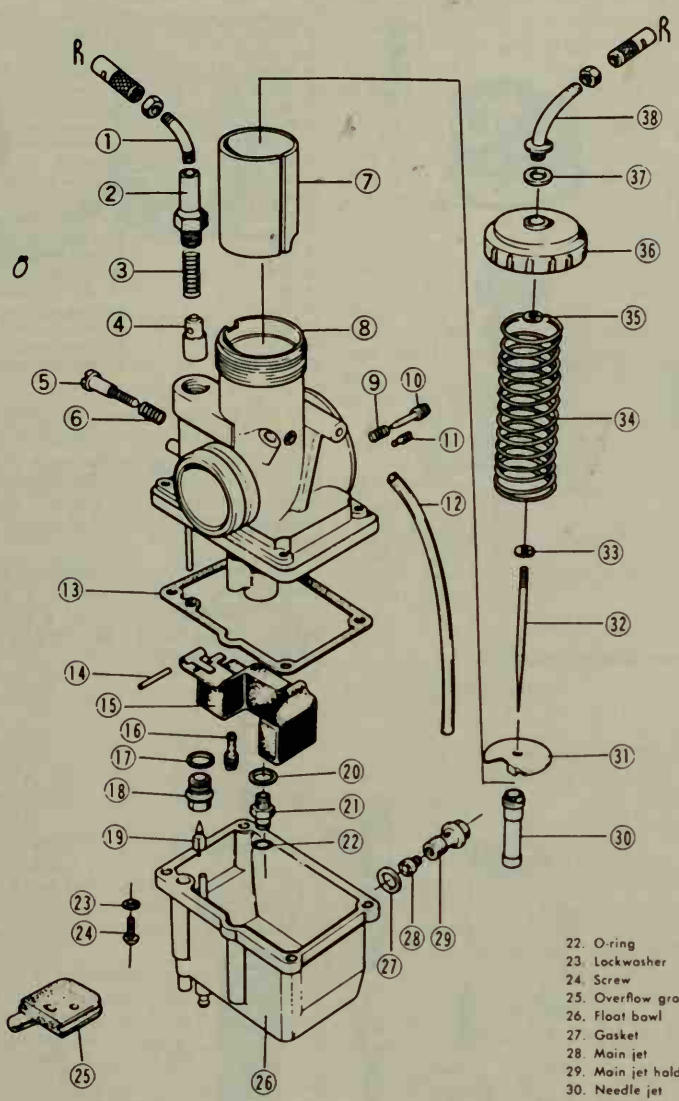
FUEL SYSTEM

NOTE: *For carburetor theory, component inspection, and troubleshooting, refer to "Carburetors" in the "General Information" section.*

All Kawasaki models covered in this manual are equipped with Mikuni carburetors.

CARBURETOR

Removal and Installation



ROTARY VALVE MODELS

The carburetor is located beneath the cover at the forward end of the right-side engine case.

1. Lift up the rubber carburetor cover. Remove the rubber plug on the front of the right engine case. Using an impact driver, if necessary, unscrew and remove the carburetor cover.
2. Unscrew the carburetor cap and pull out the throttle slide assembly.
3. Shut the fuel petcock off. Disconnect the fuel line from the carburetor.
4. With a screwdriver (slot head), loosen the carburetor mounting clamp (G-Series), which is accessible through the plug hole at the front of the carburetor case.
5. Pull the carburetor off its spigot.
6. Disconnect the overflow tube from the float bowl. Unscrew the starter plunger and pull it out of the carburetor body.
7. Drain the gasoline out of the carburetor before disassembly.
8. Installation is the reverse of the removal procedure. Be sure that all lines are firmly attached, and that the rubber grommets are properly seated.

PISTON PORT MODELS

1. Shut off the fuel petcock. Disconnect the fuel line at the carburetor.
2. Disconnect the overflow tube from the float bowl and the breather tube from the carburetor body. Slip the breather tube free of the clamp on the carburetor body.

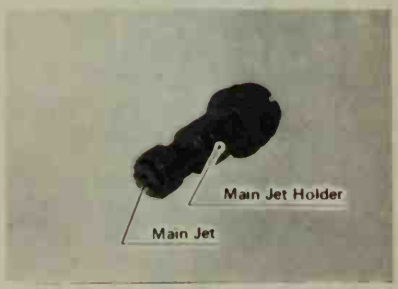
KS125 carburetor assembly

3. Unscrew the carburetor cap and pull the throttle slide assembly out.
4. Loosen the two carburetor clamps and pull the carburetor off to the rear.
5. Drain the gas out of the carburetor before disassembly.
6. Installation is the reverse of the removal procedure.

Disassembly

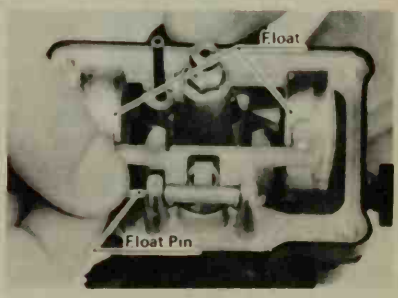
ALL MODELS

Disassembly procedures will vary slightly depending on the type of carburetor fitted.



NOTE: *Note the location of all O-rings, washers, and gaskets when disassembling the carburetors. Refer to the exploded views if necessary.*

If disassembly of the throttle slide assembly is desired, refer to the procedures below. If a throttle stop rod is used to adjust the idle speed, see Step 1 and following. On all other models, begin with Step 2.



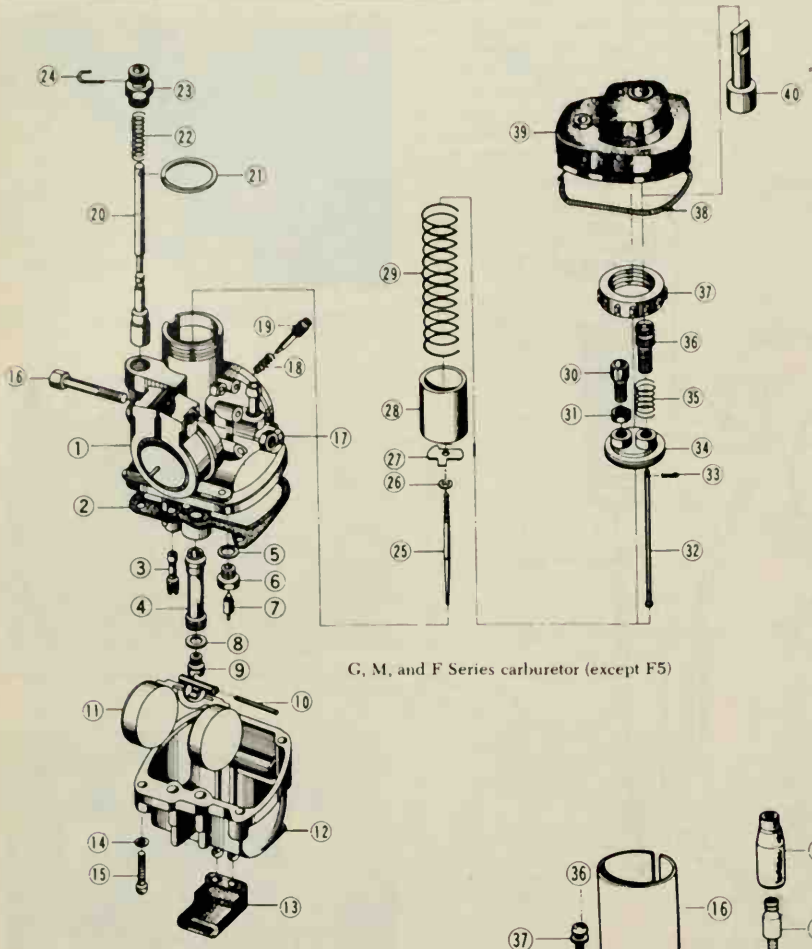
1. The idle speed adjuster screw on the carburetor cap has a small cotter pin at the top. Removing this pin will allow the throttle stop rod to be taken out of the bottom of the throttle slide.
2. Compress the throttle slide against the carburetor cap until the end of the cable protrudes from the bottom of the slide. Slip the cable end up along the slot in the slide until free, then remove the spring and the throttle slide.
3. Remove the spring seat or circlip from the inside of the slide, then turn it

To remove the throttle stop rod, first pull out the cotter pin

The main jet is removed with the main jet holder from the float bowl

Removing the float

upside down to remove the needle and clip.



NOTE: *Do not remove the needle clip unless its position is to be changed.*

4. Turn the carburetor upside down. On models with a float bowl-mounted main jet, remove the jet holder and the jet. The main jet is unscrewed from the end of the holder if replacement is desired. Remove the four float bowl screws, and remove the float bowl carefully.

NOTE: *If the carburetor is old or has never been disassembled, the float bowl may be stuck to the gasket. Use a plastic mallet to tap around the float bowl until it is free. Restraint should be exercised while doing this.*

5. On independent-float models, the floats will remain in the float bowl. If removal is desired, remove the clips which secure the floats to their shafts, and remove the floats. Push out the float arm lever pivot pin by hand or with a small punch and remove the float arm lever from the carburetor body.
6. On one-piece float assembly models, push out the float pivot pin by hand or with a small punch and remove the float assembly.

CAUTION: *Carefully note or mark the*

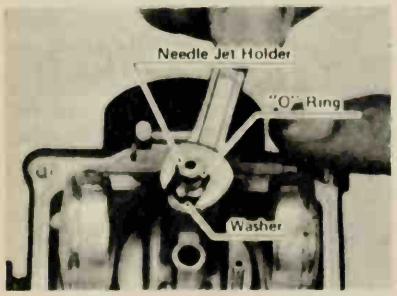
G, M, and F Series carburetor (except F5)

If this is not the case, the needle jet is recessed into a holder in the carburetor body. After removing the main jet or set bolt, use a thin knife blade or something similar to remove the washer which is press-fitted at the bottom of the needle jet.

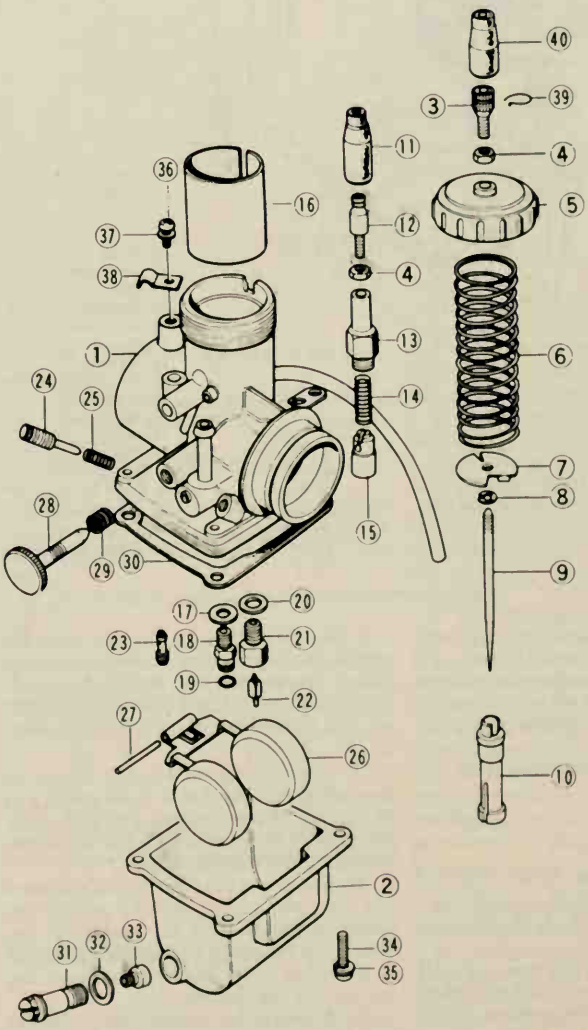
The needle jet is pressed into the carburetor body. To remove it, a wooden dowel should be used as a drift. Tap lightly on the needle jet to force the jet out of the carburetor.

top side of one-piece float assemblies, since damage could occur if the attempt were made to install the assembly in the incorrect manner.



7. Remove the float needle.

8. With a suitable socket, unscrew and remove the float needle seat.



9. Unscrew and remove the main jet on carburetors with a main jet mounted on the carburetor body.

10. On carburetors with a float bowl-mounted main jet, unscrew and remove the needle jet holder. The O-ring on this bolt *must* be replaced when the carburetor is assembled.

11. The needle jet is of two types, depending on model. If a hex-head is provided, simply unscrew and remove the needle jet in the same manner as the main jet.

F11 carburetor

Removing the needle jet

12. Unscrew and remove the pilot jet.
13. If the starter plunger is still in place, unscrew the large nut on the carburetor body and remove the plunger assembly.
14. Unscrew and remove the pilot air jet. On most models, this is located on the side of the carburetor, but on some rotary valve models it is threaded into a passage just below the carb air intake.
15. Unscrew and remove the throttle stop screw (if fitted). Both the pilot air screw and throttle stop screws are held in adjustment by small springs. Be careful that these are not lost when the screws are removed.

Assembly

1. The following parts should be replaced each time the carburetor is disassembled:
   a. Manifold gasket and manifold O-ring (if fitted);
   b. Float bowl gasket;
   c. Float needle seat gasket;
   d. Throttle stop rod cotter pin (if fitted).
2. On rotary valve models, assemble the throttle slide assembly by first fitting the carburetor cap onto the throttle cable. Install the throttle stop rod through the bottom of the slide and attach it with the cotter pin to the top of the idle adjusting screw on the carburetor cap.
3. Install the needle, making sure that the needle clip is positioned in the same groove as it was found, unless tuning changes have been made.
4. Install the spring seat, return spring, and engage the throttle cable on the slide in the reverse of the disassembly procedure.
5. Install the pilot jet, being careful when screwing the jet in that it is properly seated.
6. Install the needle jet. If the needle jet is the pressed-in type, install it as it was removed with a wooden dowel drift, tapping it into its seat from the top of the carburetor. Install the needle jet washer.

NOTE: *If this type of needle jet is used, make sure that it is installed with the cutaway at the top of the needle jet facing the ENGINE side of the carburetor.*

7. Install the main jet; tighten it securely.
8. Install the fiber float needle seat gasket onto the needle seat, and screw the needle seat into the carburetor.
9. Place the float needle into the seat, and position the float assembly over the needle, ensuring that the correct side faces up. Slip the float pivot pin into the holder.
10. Adjust the float height as outlined in Chapter 3.
11. Fit a new float bowl gasket. Install the float bowl, and install the four phillips head screws, tightening them gradually, and in an "X" pattern.
12. Refit the pilot air screw and spring. Screw in the pilot air screw until lightly seated, then back it off the prescribed number of turns given in the "Carburetor Specifications" chart at the end of this section. This is an approximate setting and may have to be readjusted when the engine is started. Install the throttle stop screw and spring.
13. Install the starter plunger in the carburetor body and secure it.
14. Install the carburetor on the manifold and install the throttle slide assembly.
15. Refer to the "Maintenance" and "Tune-Up" sections if necessary to adjust the pilot air and throttle stop screws and the throttle cable.

FUEL PETCOCK

Two types of petcocks are in use: the standard three-position type, and a diaphragm type (F5 and F7). The diaphragm petcock is left in the "on" position at all times except when switching to "reserve." Use the "prime" position to fill the carburetor float bowl if it has been emptied. No fuel should flow out of the petcock in the "on" and "reserve" positions unless the engine is running.

1. The petcocks contain a wire mesh filter which should be removed and cleaned every few months, or at 2,000 mile intervals.
2. If a sediment bowl is fitted, turn the petcock lever so that fuel will not flow, and unscrew and remove the sediment bowl, O-ring, and filter screen. On petcocks without sediment bowls, the filter screens are fitted to the petcock intake pipes inside the tank. Remove and drain the gas tank, unscrew the petcock nut, and remove the petcock from the tank.
3. Clean all metal parts in solvent. Be sure that the filter screens are clean.
4. Make sure that the petcock fully shuts off the gas (standard type), or does not leak gas in the "on" position (diaphragm type). If leakage is noted, the petcock should be replaced.
5. Check the condition of the sediment bowl O-ring, or petcock gasket, and replace it if damaged.
6. Replace the filter and sediment bowl. Do not overtighten the bowl. After installation, check for leaks.
7. If water has accumulated in the gas tank, some or most of it can be removed if the standard-type petcock is fitted by disconnecting the fuel lines at the petcock, placing a suitable container beneath it to catch the gasoline, and turning the petcock lever to the "reserve" position. Letting the fuel flow for several seconds in this manner should remove any water present around the petcock pipe in the gas tank.
8. After extended periods of time, removal and thorough cleaning of the petcock is recommended. Remove the gas tank and drain off all the fuel. Unscrew and remove the petcock body from the gas tank. Unscrew and remove the sediment bowl and filter.
9. On diaphragm-type petcocks, remove the diaphragm plate securing screws, and remove the plate and diaphragm.
10. Clean the fuel pipe filters and the petcock body thoroughly in gasoline. Be sure that all passages are clear.
11. Assembly is the reverse of disassembly. On diaphragm-type petcocks, align the air vents in the petcock body, diaphragm, and plate.

Carburetor Specifications③

Model	Carburetor	Main Jet	Needle Jet	Needle	Pilot Jet	Slide Cutaway	Float Height (in./mm)
GA1	VM19SC	160	E-4	5I2-3	17.5	2.0	0.94/24
GA2	VM19SC	160	E-4	5I2-3	17.5	2.0	0.94/24
G3SS	VM19SC	160	E-4	5I2-3	17.5	2.0	0.94/24
G3TR	VM19SC	170	O-2	4L6-3	17.5	2.5	0.94/24
G4TR	VM19SC	180	E-6	5I1-3	17.5	2.5	0.94/24
G5	VM19SC	102.5	E-4	5I1-4	17.5	2.5	0.94/24
MC1	VM19SC	75	O-2/2	4EJ7-3	17.5	2.0	3.5–5.5/0.138–0.217①
KS125	VM24SC	100R	O-4/2	4EJ3-4	30	2.5	3–5/0.12–0.20①
F6	VM24SC	125	O-4	4J13-3	25	2.5	1.04/26.5
F7	VM26SC	105	O-2	4EJ3-3	30	2.5	1.04/26.5

F5	VM32SC	132.5	O-8	5FL11-2	35	2.5	0.43/11②
F11	VM30SC	112.5	O-8	5DJ19-3	40	2.5	0.10–0.18/2–4①

① Distance between the actual fuel level and the bottom of the carburetor body
② Distance between the needle jet housing and the float arm
③ May vary according to year, manufacturing lot, etc.

12. Check the condition of the sediment bowl O-ring and replace it if damaged. Check the mounting nut gasket and replace it if cracked or crushed.
13. After assembly, check for leaks.
14. On diaphragm petcocks, be sure that the vacuum line is airtight, or fuel flow will be cut off. The vacuum line should be completely free of cracks and should be firmly attached at both ends. Replace the line if damaged, or if the ends have stretched, resulting in loose fitting at the connection points.

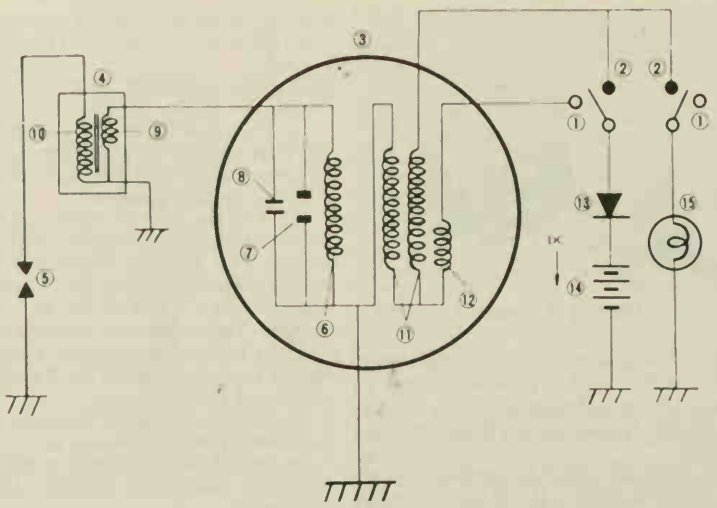
ELECTRICAL SYSTEMS

FLYWHEEL MAGNETO

Charging and Lighting System

A heavy-load wire and a light-load wire are tapped from the magneto to supply the greatly varying requirements of day and night (lights on) operation. On the MC1, KS125, F6, and F8 models, three charging taps are attached to the magneto. The pink wire is used when the headlight is on, during night operation. The blue, green, or yellow/green wire is used when the headlight is off. On F6 and F8 models, if you find that your battery is constantly undercharged, connect the blue wire from the magneto to the blue wire of the main switch. If the battery is constantly overcharged, connect the yellow/green wire from the magneto to the blue wire on the main switch.

In the F5 and F11 models, voltage input to the battery is controlled by a voltage regulator which senses battery terminal voltage and controls the charging rate accordingly.



NOTE: *When the key is turned to the night riding position the voltage regulator is disconnected from the circuit. Therefore, if one of the light bulbs is burned out, the battery may be overcharged or the other bulbs burned out due to the excessive voltage.*

Flywheel Magneto Component Tests (Except F5 and F7)

MAGNETO IGNITION COIL

Place a strip of paper between the breaker points to insulate them. Perform the following resistance tests using an ohmmeter.

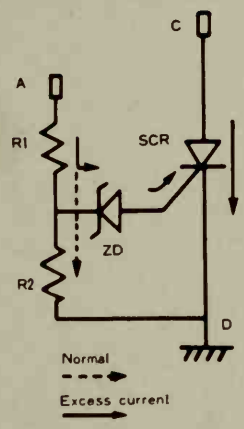
1. Coil resistance:
a. Measure the resistance between the black lead and ground. The coil is good if the resistance is approximately 0.5 ohms for G and F Series (except F11); 1.2–1.3 ohms for the F11, and 1.21–1.48 ohms for the M and KS Series models.
2. Insulation resistance:
a. Disconnect the ground wire from the coil to the magneto base;

Flywheel magneto wiring diagram

1. Daytime running
2. Nighttime running
3. Flywheel magneto assembly
4. Ignition coil
5. Spark plug
6. Magneto coil
7. Contact breaker
8. Capacitor
9. Ignition primary coil
10. Ignition secondary coil
11. Lighting coil
12. Differential winding coil
13. Rectifier
14. Battery
15. AC lamp load (headlamp and taillamp)

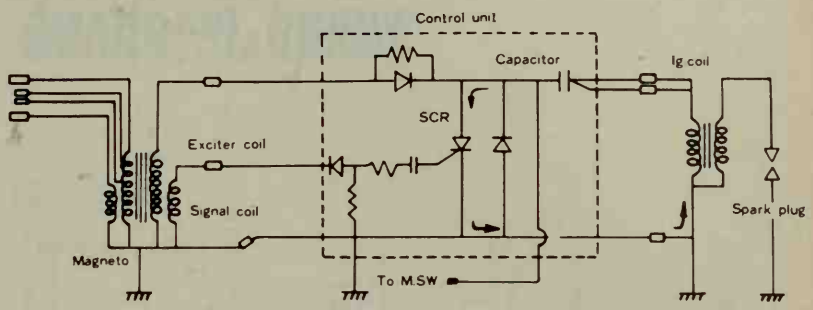
b. Measure the insulation resistance between the iron core and the coil. The reading should be over 5.0 megohms.

CONDENSER



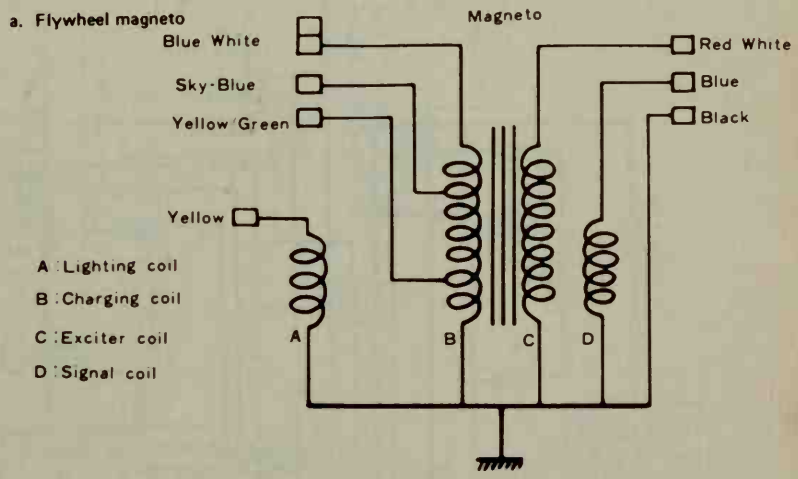
1. Capacity:
a. The condenser capacity should be between 0.18–0.25 microfarads.
2. Spark quality:
a. Connect the positive and negative wires of the condenser to a 6 volt DC power source for a few seconds to charge it;
b. Disconnect the power source and touch the two wires together. If a spark is produced, the condenser is good.
3. Insulation resistance:
a. Disconnect the ground wire of the condenser;
b. Measure the insulation resistance between the outer case and the positive terminal. The reading should be above 5.0 megohms.

LIGHTING AND CHARGING COILS



1. Coil resistance:
a. Measure the resistance of each coil with an ohmeter and compare the readings with the specifications in the accompanying chart.
NOTE: *The lighting coil for the GA1—A and GA2—A models also serves as a charging coil when the headlight is turned on.*
2. Insulation resistance:
a. Disconnect the ground wire;
b. Check insulation resistance between the iron core and the coil. The coil is good if the reading is above 0.5 megohms.

Lighting and Charging Coil Specifications



Model	Lighting Coil		Charging Coil	
	Yellow	Pink	Blue	Yellow/Green
GA1-A GA2-A	0.41 Ω ± 10%	—	0.36 Ω ± 10%	—
G3SS-A G3TR-A G4TR	0.55 Ω ± 10%	0.55 Ω ± 10%	1.20 Ω ± 10%	0.29 Ω ± 10%
F6	0.48 Ω ± 10%	0.48 Ω ± 10%	0.60 Ω ± 10%	0.54 Ω ± 10%
F8	0.30 Ω ± 10%	0.30 Ω ± 10%	0.58 Ω ± 10%	0.57 Ω ± 10%
F11	0.2–0.3	0.5–0.6	—	—
KS125	0.44	2.55	5.35	—

Magneto coils and coil leads (CDI)

CAPACITOR DISCHARGE IGNITION SYSTEM

Testing

FLYWHEEL MAGNETO

The coils installed in the magneto should be checked with an ohmmeter. When testing the coils, be sure to disconnect the wires from the control unit, the rectifier, and the main switch. Resistance values are given in the accompanying chart.

IGNITION COIL

Check the ignition coil with an ohmmeter. Connect the meter to the terminals of each of the windings (primary and secondary), in turn. Resistance values are given in the accompanying chart.

CONTROL UNIT

A special tester is necessary for checking the CDI control unit to avoid damage to the components. It is recommended that this operation be left to a Kawasaki dealer.

Magneto Coil Resistance (F7 and F5)

Coils	Connection of Tester		Standard resistance
Exciter Coil	Red/White	Black	220 Ω ± 10%
Signal Coil	Blue	Black	75 Ω ± 10%
Charging Coil	Blue/White	Black	0.23 Ω ± 10%
Lighting Coil	Yellow	Black	0.23 Ω ± 10%

Voltage Regulator Service (F5 and F11)

PRECAUTIONS

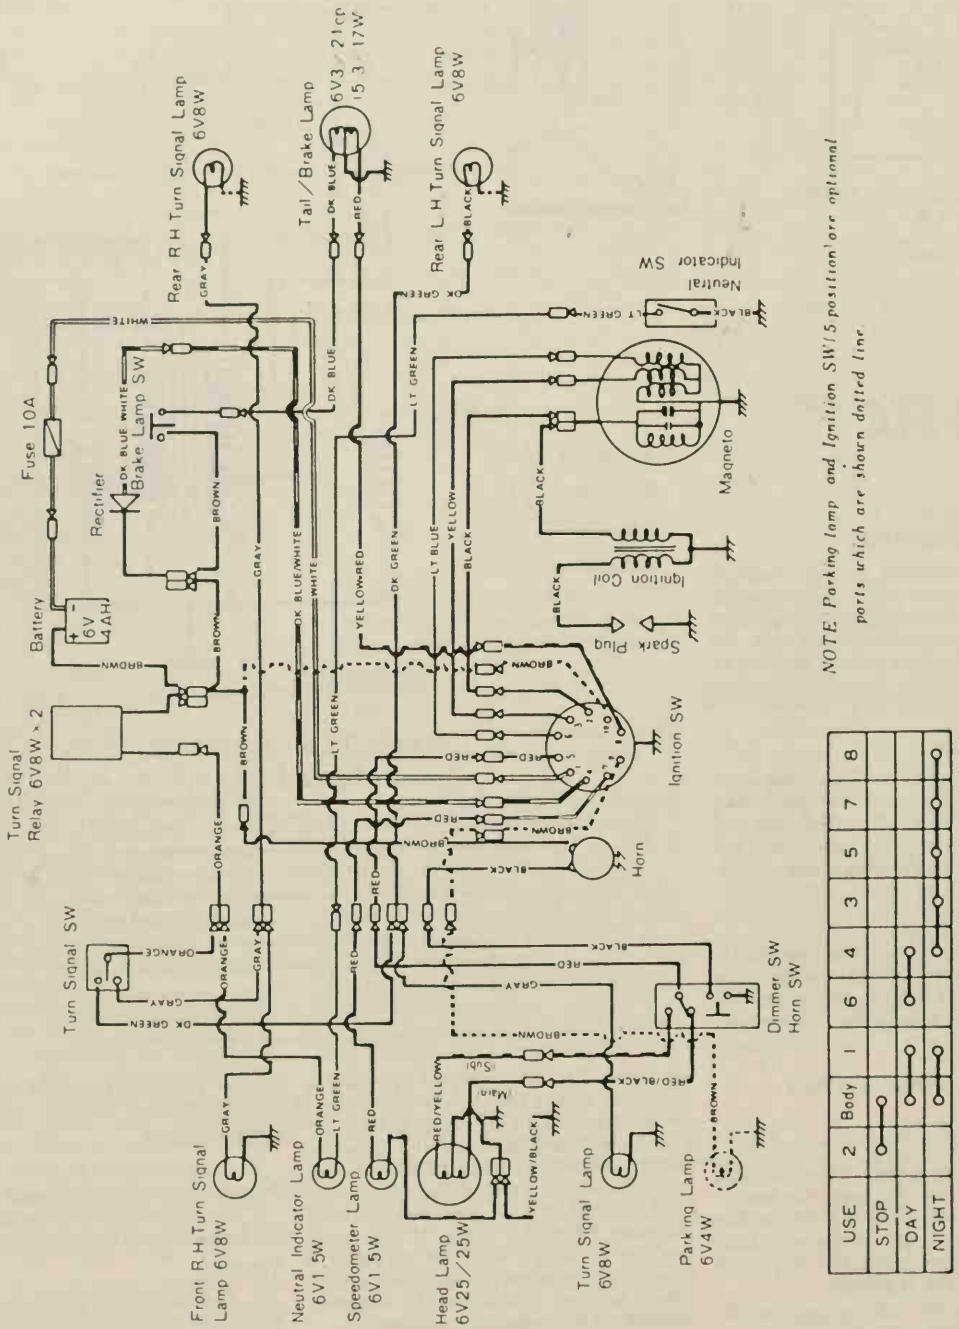
1. Do not remove the rubber cap (F5), which projects from the regulator body.
2. Do not loosen the nut in the rubber cap (F5), or the screw in the regulator body (F11), which controls the rate of heat transfer of the regulator.
3. Be sure to turn off the ignition before disconnecting any wiring.
4. When installing the regulator, make sure that the wiring is connected correctly. Improper wiring can damage the regulator and battery.

TESTING

1. Check the resistance between the brown wire and the regulator case. If there is resistance, the regulator must be replaced.
2. Before beginning this test the battery must be fully charged. Connect a voltmeter across the battery terminals—the positive lead of the meter to the positive battery terminal and the negative meter lead to the negative battery terminal. With all lights off and the engine running at 5,000 rpm, the meter should read between 7.2 and 8 volts. If the meter reads more than 8 volts the regulator is defective. A reading of less than 7.2 volts would indicate that either the magneto, rectifer, or the regulator is defective.

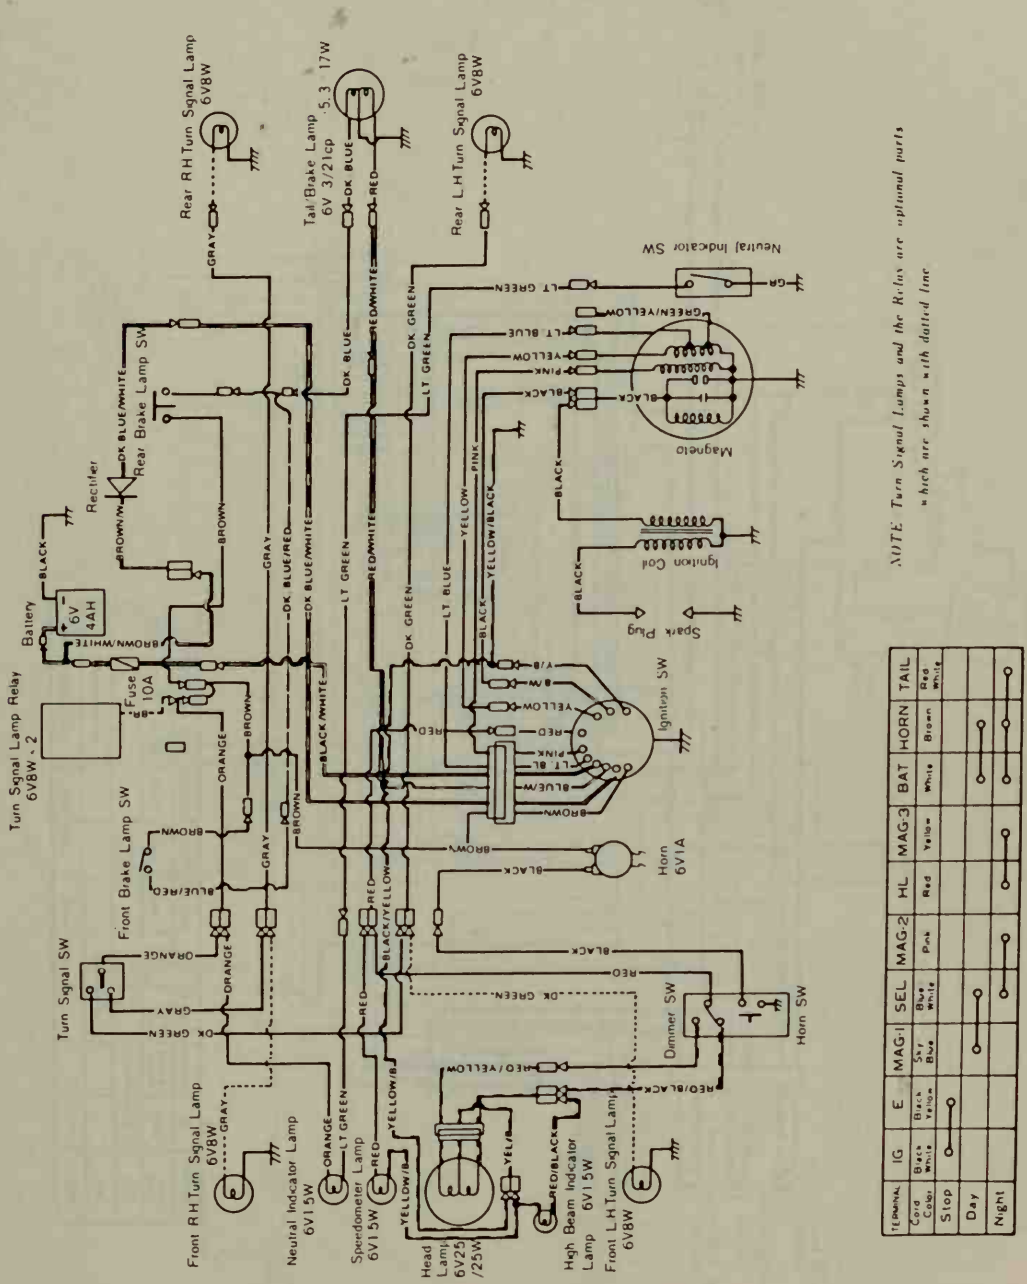
RECTIFIER

The selenium rectifier functions to convert the alternating current produced by the magneto into direct current. The rectifier used on these models is a half-wave rectifier, allowing only half the wave of alternating current to pass, interrupting the other half.



Precautions

1. Do not run the motorcycle with the battery removed or disconnected.
2. Do not run the motorcycle without the fuse being installed properly.



Testing

1. Connect the negative lead from the battery (6 volt) to the blue/white wire on the rectifier.
2. Connect a test light (for which the taillight bulb can be used), between the positive battery lead and the brown wire on the rectifier.
3. If the bulb lights, the rectifier is defective and must be replaced.
4. Reverse the leads (negative battery lead to brown wire and positive lead to blue/white wire).
5. If the bulb does not light in this case, the rectifier should be replaced.

WIRING DIAGRAMS

F11

CHASSIS

WHEELS, BRAKES

Front Wheel Removal and Installation

1. Support the front wheel several inches off the ground by placing a crate or the like beneath the motorcycle if necessary.

2. Disconnect the brake cable from the handlebar lever and then from the lever on the brake plate. Detach the cable from the adjuster if the adjuster is equipped with a slot for this purpose. If not, unscrew the adjuster from the brake plate. If the brake cable is fitted with an adjuster nut at the end of the cable as on M Series, remove the adjusting nut and pull the cable from the brake plate.

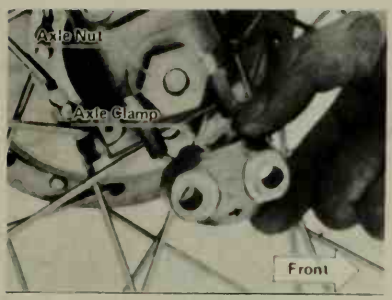
3. Unscrew the end of the speedometer cable from the brake plate.

4. On F5 and F8 models, disconnect the brake anchor from the brake plate.

5. The front wheel is secured in a number of ways depending on model. On G and M Series models, the axle is held only by the axle nut. On the F6, a pinch-bolt is fitted to the bottom of the fork sliders. On other models, an axle cap (secured by two small nuts) is used.

6. On models with axle caps, remove the two nuts from each cap and remove them. The front wheel can now be removed. On other models, remove the cotter pin from the end of the axle. Remove the axle nut and loosen the axle pinch-bolt if fitted. Insert a phillips head screwdriver or similar tool into the axle and pull it out of the sliders.

NOTE: *Twisting the axle while pulling it out or tapping the threaded end with a plastic mallet may be necessary to remove it. Lifting the wheel slightly to take the weight off the axle may also facilitate removal.*



7. On some lightweight models, an axle spacer on the left-side of the hub protrudes about an inch out of the oil seal. This spacer should be oiled lightly and then taken out of the seal using a twisting motion. If a dust cover is fitted to the hub, remove it now to avoid loss during handling of the wheel.

8. Refer to the wheel component service sections below if necessary. Installation is the reverse of the removal procedure. On all models (except F6 and F8), ensure that the brake anchor cast into the brake plate is engaged with the slot in the fork slider. On F6 and F8 models, be sure that the brake anchor is firmly fastened to the brake plate and the locking washer is bent up against the head of the brake anchor bolt. Tighten the axle nut or axle caps to the torque given in the "Chassis Torque Specifications" chart at the end of this section. Using a new axle nut cotter pin, if fitted, is recommended. On models with axle caps, install the axle cap so that the arrow is pointing toward the front of the motorcycle.

When installing the wheel make sure that the ridge on the brake plates is located between the ridges on the fork slider

CAUTION: *The axle caps are machined unevenly (one side is slightly higher than the other), the high side must face the front. The front bolt should also be tightened first so that a small gap exists between the bottom of the fork slider and the axle cap at the rear. If in doubt which side is the high side, place a straightedge across the top of the cap; the high side should be apparent.*

Install the axle cap so that the arrow is pointing to the front

Rear Wheel Removal and Installation

G SERIES

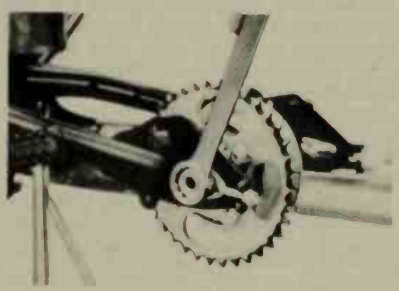
All models are fitted with a single-leading shoe rear brake which may be either rod or cable activated. The rear wheel can be removed without disturbing the sprocket and chain. On some models it is necessary to remove the muffler to allow the axle to be taken out.

1. Remove the brake anchor cotter pin. Remove the anchor nut and detach the anchor from the brake plate.
2. Unscrew and remove the brake adjuster nut. Depress the brake pedal and disconnect the brake cable or rod from the brake plate lever. On cable-operated brakes, disconnect the cable from the brake lever and the cable adjuster from the holder on the brake plate. Remove the spring and place it along with the adjuster nut and clevis pin fitting in a safe place.
3. Loosen the chain adjuster locknut on each adjuster. Then back off the adjuster bolts to allow some free-play of the rear wheel.
4. Remove the muffler if necessary to allow removal of the axle. Remove the axle nut cotter pin, the axle nut, and tap the axle using a plastic mallet while pulling it out with a twisting motion.
5. After the axle is removed, remove the axle spacer on the right-side of the wheel, and the right-side chain adjuster. Pull off the brake plate and remove it from the machine. Pull the wheel as far as possible to the right, and remove it from the machine. On some models it may be necessary to lean the motorcycle slightly to the left to remove the wheel.
6. Installation is the reverse of the removal procedure. When fitting the wheel, ensure that the driving tabs on the sprocket assembly are engaged with the slots in the hub's rubber dampers. Adjust chain tension and the rear brake in that order. Tighten the axle nut to the torque given in the "Chassis Torque Specifications" chart at the end of this section.

NOTE: *Install the masterlink spring clip so that the open end of the clip faces the opposite direction of chain rotation.*

OTHER MODELS

1. Remove the brake adjusting nut and disconnect the brake cable or rod from the brake lever.
2. Disengage the brake anchor from the brake plate.
3. Disconnect the drive chain at the masterlink. Disengage the chain from the rear sprocket.
4. Remove the axle nut and washer. Pull the axle out and remove the wheel. Install the chain adjusters and any spacers onto the axle in the order in which they were removed for safekeeping.
5. Installation is a reversal of the removal procedure. Be sure that the open end of the masterlink spring clip faces the opposite direction of chain travel. Tighten the axle nut to the torque given in the "Chassis Torque Specifications" chart at the end of this section.



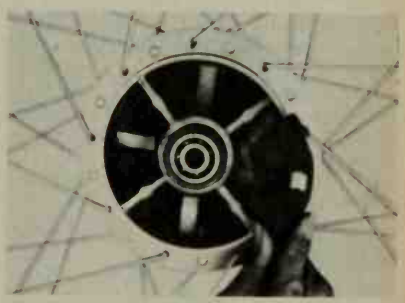
Sprocket Assembly

G SERIES

The rear sprocket assembly consists of the sprocket, sprocket hub, sprocket hub bearing, and the rubber dampers which will remain in the wheel when it is removed.

Removal and Disassembly

1. Remove the rear wheel and disconnect the drive chain. Unscrew the large sprocket hub nut and remove the assembly from the swing arm.



To remove the sprocket hub, disconnect the drive chain and remove the large sprocket nut

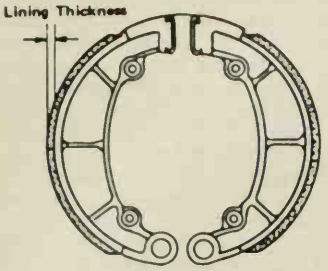
2. Bend down the tabs on the sprocket nut locking plates. Unscrew the nut and remove the sprocket from the hub.
3. To remove the hub bearing, first remove the sprocket shaft by tapping it out from the sprocket side of the hub. Use a plastic mallet or block of wood so that the sprocket shaft threads will not be damaged when struck.
4. Take off the sprocket shaft collar.
5. Use an elbow-shaped tool to pry out the oil seal. If the oil seal is damaged on removal, as is likely, a new one must be fitted.
6. Drive the bearing out toward the sprocket side of the hub with a suitable drift or bearing driver. Tap the bearing evenly around its circumference to avoid distorting the hub.

Inspection

1. For bearing inspection and lubrication, refer to "Wheel Bearings," below.
2. Check the condition of the sprocket. If the sprocket is warped, or if the sprocket teeth are worn or hooked, the sprocket should be replaced along with the chain and the countershaft sprocket.
3. Check the condition of the sprocket nuts, bolts, and locking plates. Replace any nuts or bolts with rounded flats, stripped threads, or those which are bent or cracked. Bolts must be tightened securely upon installation. It is also recommended that they be secured with a thread locking compound. The locking plates must not have fatigued or cracked edges, since these are used to lock the nuts in place. Replace the plates if damaged in any way.
4. Check the condition of the oil seal and replace it if the lips are damaged.
5. Inspect the sprocket shaft for broken or stripped threads.
6. Check the condition of the rubber dampers in the wheel hub. These take up any driveline shocks when the clutch is released and have an important effect on chain and sprocket life. Replace any damper which is hardened, crushed, or damaged.

Check the condition of the rubber dampers

In instances where the damper is a tight fit in the hub, some engine oil or dishwashing liquid can be used to facilitate removal and installation.



Assembly

1. Assembly is the reverse order of disassembly procedure.
2. Lubricate the bearing as described in "Wheel Bearings," below. The bearing should be driven into place with a bearing driver or a suitable substitute.
3. Grease the lips of the oil seal before installation. The seal should be pressed into the hub with care.
4. Tap the sprocket shaft into the hub from the wheel side.
5. When connecting the chain masterlink, install the spring clip closed end facing the direction of chain rotation. Tighten the sprocket hub nut securely.

Drum Brake Service

All models use single-leading shoe brakes front and rear. Kawasakis use brakes in which the lining is bonded to the brake shoe, therefore, are purchased and replaced as a single unit.

1. Brakes can be inspected in place on the brake plate.
2. Inspect the shoes for wear. There should be at least 0.12 in. (3 mm) of lining material left (measured at the lining's thinnest point), or the shoes must be replaced.

Check brake lining thickness

3. Use a large vernier caliper to measure the inside diameter of the brake drum. If the diameter is found to be less than the service limit given in the "Chassis Specifications" chart at the end of this section, the hub should be replaced.

4. Inspect the linings for scoring or grooves. These may be caused by particles of dirt which have entered the drum. If badly scored, the shoes should be replaced. If scoring of the shoes is evident, it would be wise to inspect the brake drum for the same type of damage.

Be sure that there is no oil or grease present on the brake linings. Oil-impregnated linings must be replaced. If the linings do show this condition, determine the source of the lubricant: defective wheel bearing oil seals, excessive chain lube, etc.

5. If the linings are usable, rough up the surface with a piece of coarse sandpaper. Then clean the linings thoroughly with alcohol or laquer thinner. Clean the brake drum with the same solvent.

6. To disassemble the brake plate, simply grasp each shoe and fold them toward the center of the brake plate. They may be installed in the same manner.

7. Remove the brake lever pinch-bolt and pull the lever off the splined brake camshaft.

8. Push the brake cam out of the brake plate from the outside using hand-pressure or by tapping with a plastic mallet. Remove the dust seals (if fitted), from the brake plate.

9. Check that the brake lever pinch-bolts are not bent. This can easily happen if they are overtightened. Replace any bolts which are in this condition. Inspect the brake lever splines and replace the lever if these are worn or torn.

10. Inspect the splines on the brake cam. These should be in good condition. Check that the brake cam is not bent and that it can rotate freely in the brake plate passage. If it will not, use a fine grade of sandpaper on the camshaft and the surface of the brake plate passage.

11. Clean the cam thoroughly in a solvent to remove any old grease, rust or corrosion. Use sandpaper or emery cloth to polish the cam. Clean off any residue; before reassembly, smear the cam with chassis grease.

12. Inspect the brake plate for cracks or fractures, and replace it if necessary.

13. Check the condition of the brake springs, noting any twisted or fatigued hooks. Replace any broken, rusted, or old springs with new ones. Be sure that the lever springs are in good condition. Check the length of the brake springs against the specification given in the "Chassis Specifications" chart at the end of this section.

14. Clean all parts thoroughly with a suitable solvent, making a special effort to remove the dust and built-up dirt from the brake plate.

15. When reassembling the hub, note the following points:

a. Ensure that the brake cam is lubricated with chassis grease and that any shims which were on the cam are in place;

b. The use of new dust seals is recommended;

c. Lubricate the brake shoe pivot points with a little grease;

d. Install the shoes as on removal. Hook them together with the springs, and fold them down over the brake cam and pivot.

Brake Drums

1. Upon disassembly of the hub, inspect the brake drum surface for condition. The drums must be clean and free from score marks or rust.

2. Rust can be removed from the drum surface with sandpaper. Polish the surface until it is shiny, then clean it thoroughly.

3. Alcohol or lacquer thinner can be used to remove dirt or deposits from the drum.

4. The drum should be checked for concentricity. An out-of-round condition is usually noticeable as an on-off-on feeling when the brake is applied while riding. With the wheel assembly mounted on the machine, spin the wheel while applying the brake very lightly. The rubbing noise of the brakes against the drum should be heard for the entire revolution of the wheel.

5. An out-of-round condition and most scoring can be removed by having the drum turned on a lathe.

Wheel Bearings

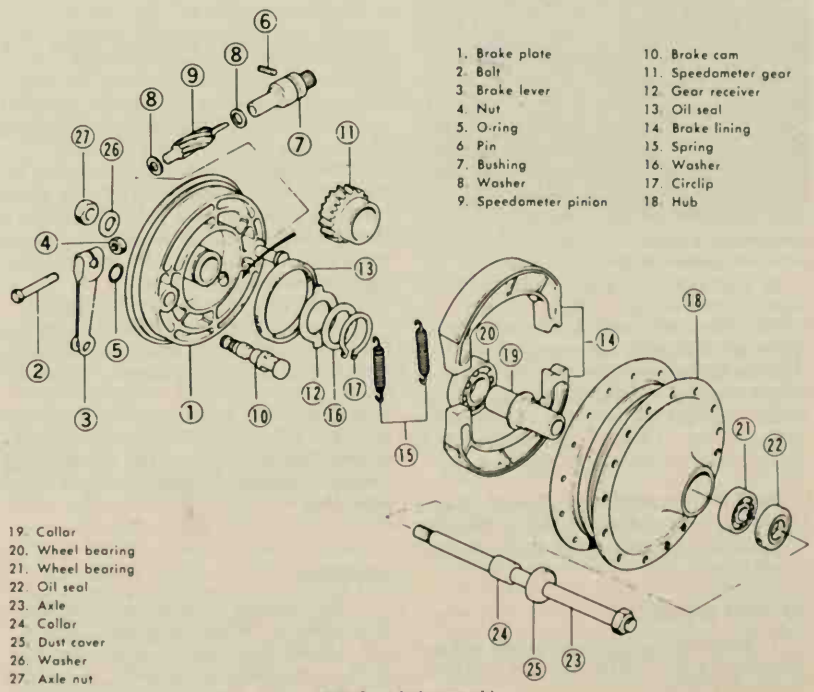
REMOVAL

Removal of the wheel bearings necessitates removing the hub oil seals. These must be replaced with new ones upon reassembly. Clean the outside of the hub before removing the wheel bearings.

1. Remove the wheel and take out the brake plate.

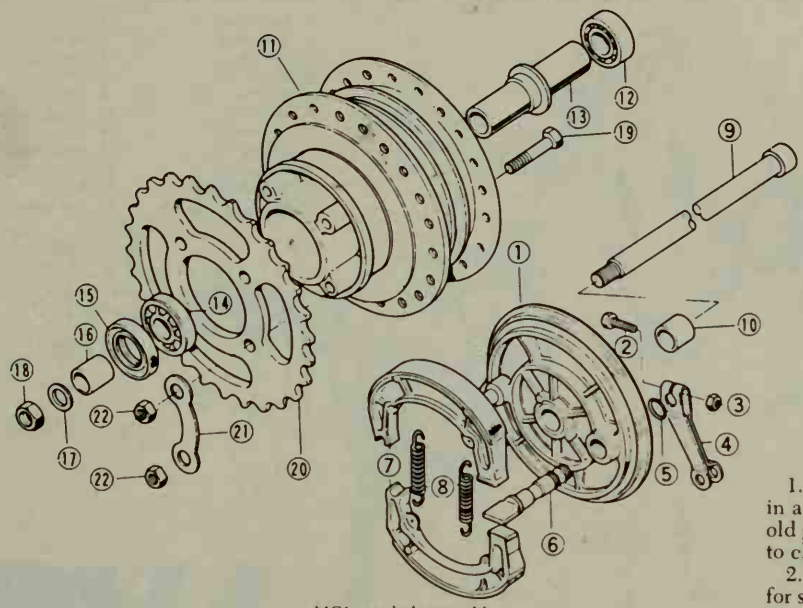
2. Remove any dust covers, dust seals, or axle spacers fitted to either side of the hub.

3. Pry out the oil seals on either side of the hub using a small screwdriver, or, preferably, an elbow-shaped tool.



4. Remove the bearing retainer snap-ring (if fitted).

5. Remove the first bearing by tapping the bearing spacer tube; the spacer tube can be removed with the first bearing. To remove the remaining bearing, reach through the hub with a drift and tap the bearing evenly around its circumference. When removing the bearing, keep the bearing surface at a 90° angle to its seat in the hub.



NOTE: *On some models, especially high mileage machines, the hub should be heated gently with a propane torch in the vicinity of the bearing bosses to facilitate removal.*

INSPECTION

NOTE: *The following bearing inspection checks refer to the sprocket hub bearing as well as the wheel bearings.*

27. Brake lever
28. Collar
29. Axle

KS125 rear hub assembly

1. Clean the bearings and spacer tube in a suitable solvent, removing all of the old grease. At this point, it would be wise to clean out the hub as well.

2. Check the bearing bosses in the hub for scuffs, cracks, or distortion. If they are in any way damaged, the hub must be replaced.

3. Check the condition of the spacer tube and replace if damaged.

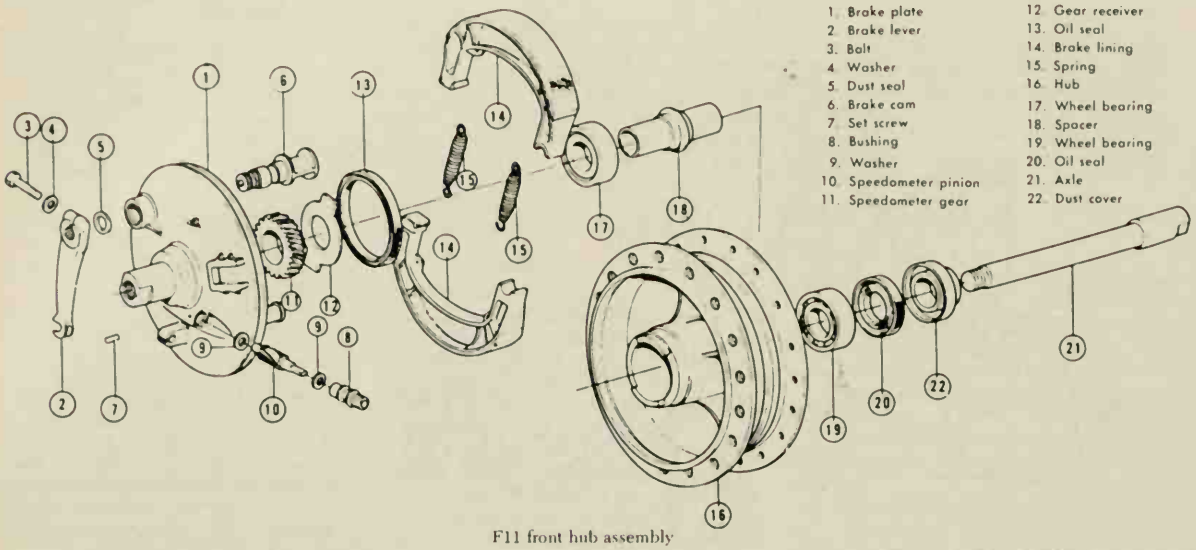
4. Apply a few drops of light oil to the bearing, and spin it. The bearing must rotate smoothly and freely. Any roughness or binding in rotation will necessitate a new bearing.

5. Place the bearing on a flat surface. Place your fingers on the outer bearing race to hold it steady. Try to move the inner race back and forth. In a good bearing, it will not be possible to move the inner race. If it is, the bearing must be replaced.

6. Note that bearings must be replaced in pairs.

ASSEMBLY

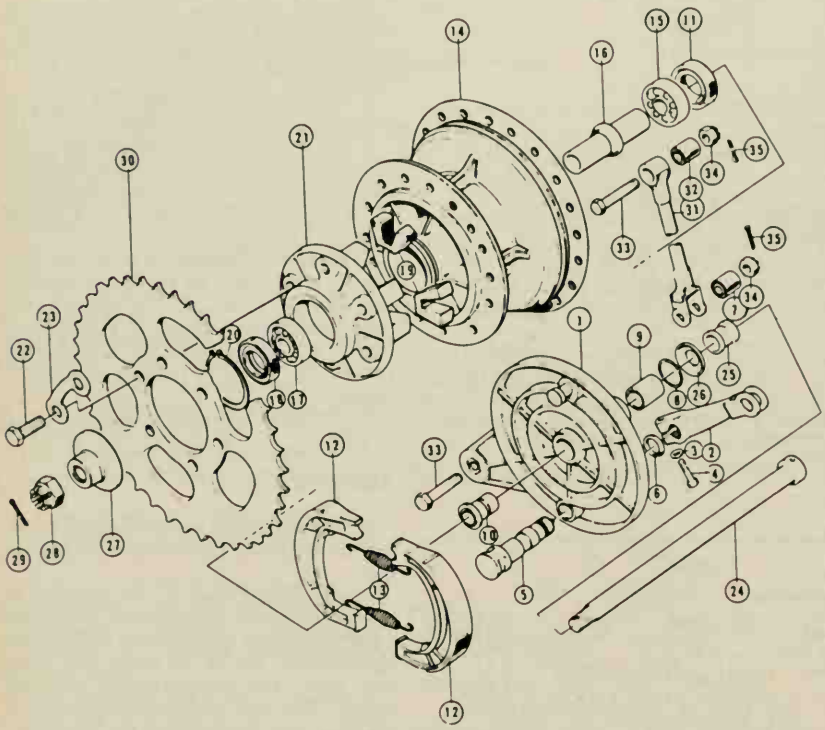
1. Obtain a good grade of wheel bearing grease to lubricate the wheel bearings.



2. Pack the grease in the bearing. A common method of doing this is to place a goodly amount of the grease in the palm of one hand. Taking the clean, dry, bearing, press one section of it into the grease. Turn the bearing until the grease has been deposited around the entire circumference. The packing process is complete when the grease begins to come out of the upper side of the bearing. Place an amount of grease in the hub as well.

3. Heat either side of the wheel hub with a propane torch as on removal of the bearings. Place one of the bearings in the hub, and make sure that it is seated.

Any bearing to which a retainer is fitted should be installed first. On most machines the axle can be used as a drift to install the bearings. Insert the axle into the bearing until the large diameter end rests on the bearing. Center the bearing in the bearing boss, then strike the axle sharply until the bearing is seated.



4. Fit the spacer, and install the other wheel bearing.

5. Press in new oil seals on both sides of the hub.

35. Cotter pin

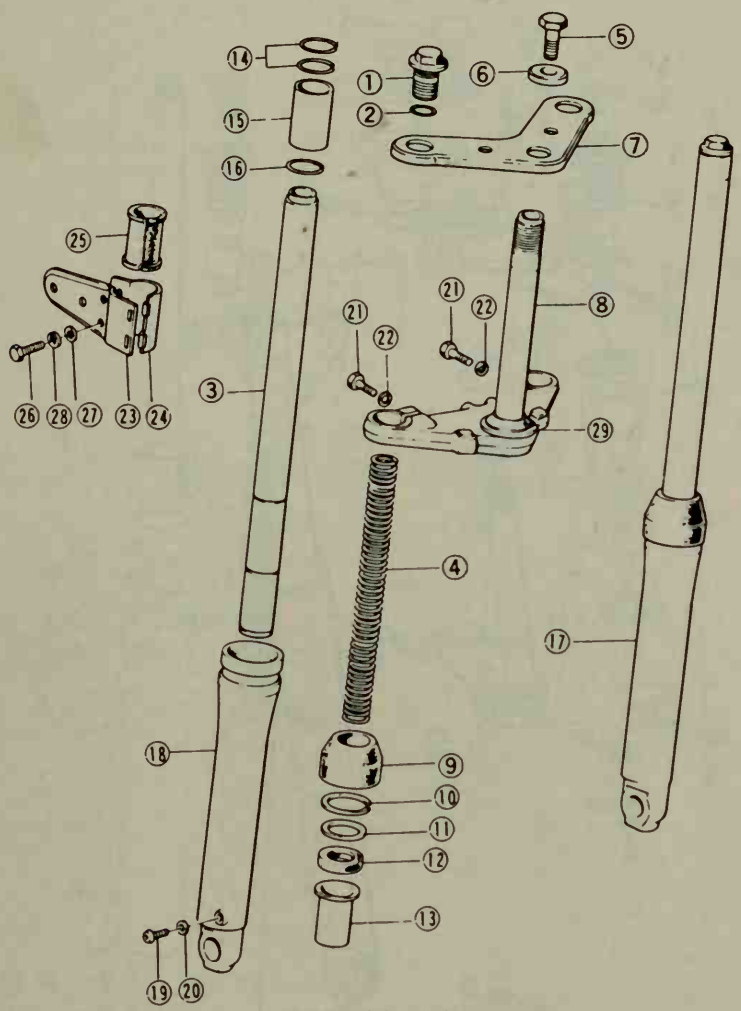
Remove the positioning circlip (if fitted)

Loosening the lower triple clamp pinch-bolts

FRONT FORKS

Removal

ALL MODELS



1. Remove the front wheel and fender.
2. Remove the headlight. Remove the positioning circlip from the fork tube (if fitted).
3. Loosen the fork filler caps.
4. Loosen the upper (if fitted), and the lower triple clamp pinch-bolts.
5. Withdraw the fork legs one at a time from the steering stem. If the fork legs resist removal, spread the lower triple clamp with a wedge and tap the fork leg out with a soft-faced mallet.

Disassembly

The following procedures are given for one fork leg, but apply to both.

M SERIES

1. Remove the fork filler cap from the top of the fork tube. Remove the spring from the top of the fork tube, invert the fork leg over a suitable container, and pour out the oil.
2. Slide the dust cover up and off the fork tube.
3. Remove the circlip and washer from the top of the slider.
4. Grasp the slider in one hand and the fork tube in the other, and pull them

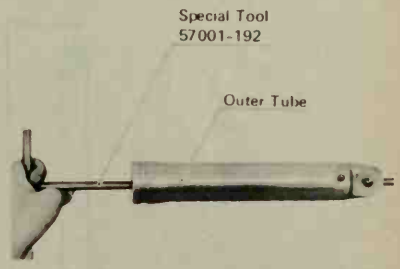
10. Circlip	20. Gasket	

Removing the circlip from the top of the fork slider

Pull the fork tube from the slider with a sharp jerk

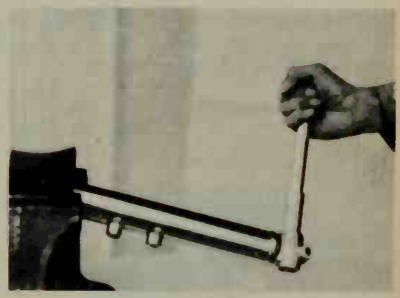
apart with a sharp jerk. Remove the oil seal and valve from the top of the fork tube.

5. Using an impact driver, remove the screw from the bottom of the slider. This screw is threaded into the damper rod. If the damper rod turns, it will have to be held with a special tool (Tool No. 57001-192), while the screw is removed.



G SERIES AND F6

1. Remove the dust seal, spring, dust boots, and spring guide. Drain the oil from the fork legs.



2. Place the fork leg in a vise, which is protected with strips of rubber, and clamp the jaws on the outer tube nut.

NOTE: *Do not use excessive pressure or the tube will be distorted.*

3. Fit the axle shaft in the bottom fork leg and turn it counterclockwise. Separate the inner tube and bottom fork leg.

Removing the screw from the bottom of the fork tube while holding the damper rod with the factory tool

Clamp the slider nut in a vise and screw the slider out using the front axle

OTHER MODELS

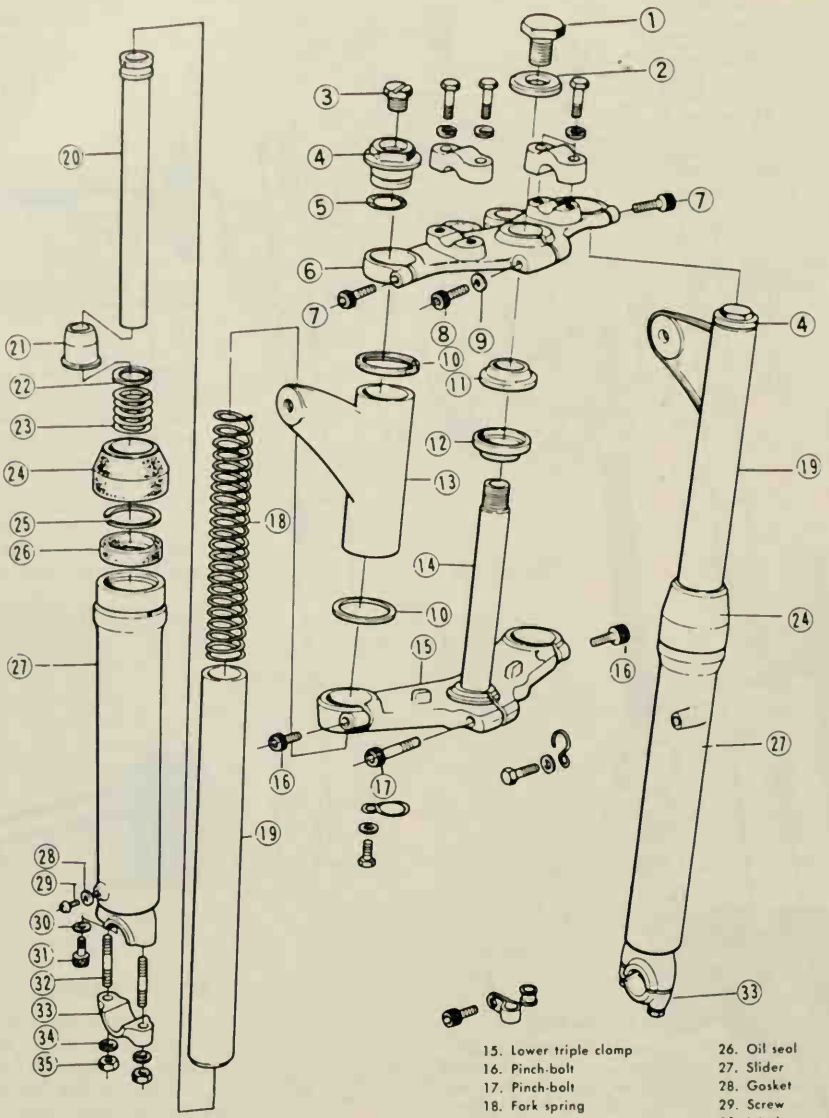
1. Remove the fork filler cap on the top of the fork tube. Remove any spring guides or spacer (if fitted), and the spring.

2. Invert the fork leg over a suitable container and empty the fork of oil.

3. Slide the dust cover off the top of the fork tube. Turn the fork leg upside down and rest the top on a block of wood. Using an impact driver, remove the allen bolt from the bottom of the fork slider. This bolt is threaded into the damper rod; if the rod turns, it will have to be held with the factory special tool.

4. Pull the fork tube out of the slider. Remove the circlip, washer, and oil seal from the top of the slider.

5. Remove the damper rod and rebound spring from the fork tube.



Inspection

ALL MODELS

Inspection procedures are applicable to all types of forks, with allowances for the type of components fitted.

1. Clean all metal parts in a suitable solvent.

2. The fork tubes must be perfectly straight. If a set of V-blocks and a dial gauge are available run-out should be checked. If a tube is bent more than 0.06 in. (1.5 mm) (true indicated reading), the tube should be replaced. If absolutely

necessary, a tube which is bent but not kinked can be pressed to straighten it, but this is not recommended.

3. If chrome plated, the plating must be in good condition over the length of the fork tube. All rust and corrosion should be removed by some low-abrasive method.

Assembly and Installation

ALL MODELS

1. Assembly is the reverse of the disassembly procedure. Note the following points.

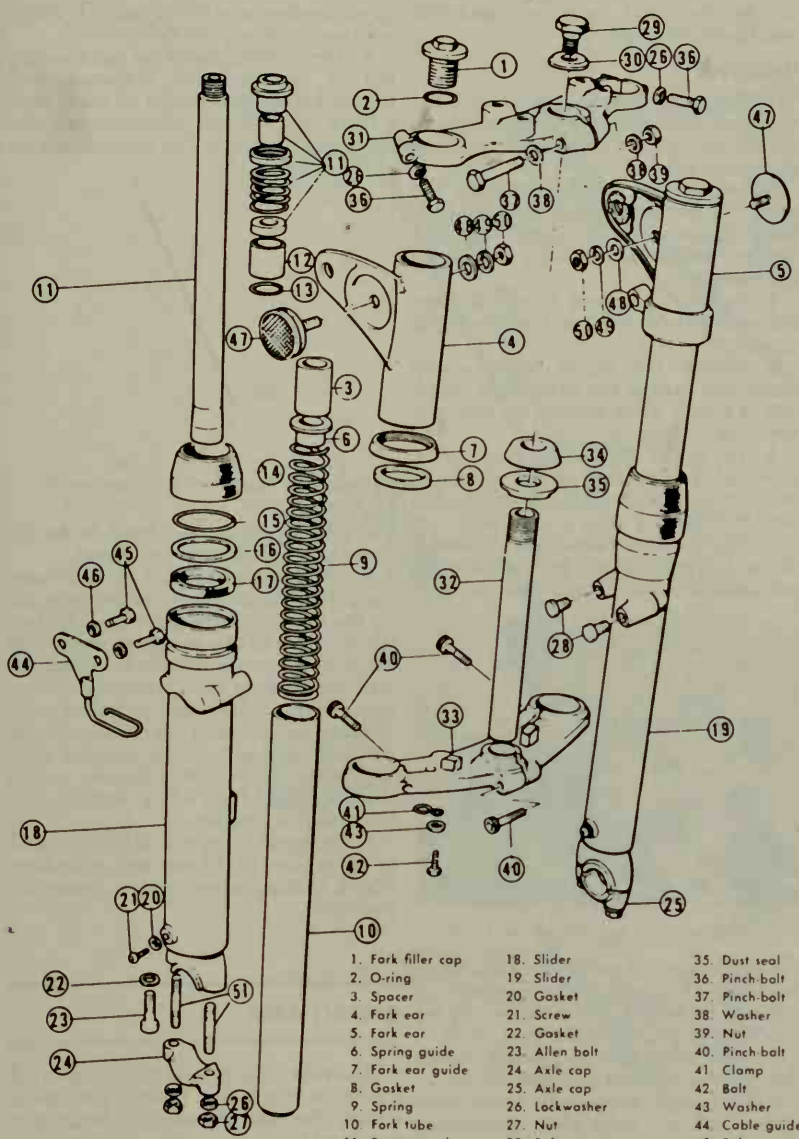
2. All O-rings, oil seals, and felt washers must be replaced.

3. Slider oil seals should be pressed directly into the slider or circular nut (depending on fork type), with a suitable drift which will cover the whole seal. This will minimize chances of distorting the seal when installing it and will allow it to be fully seated. On some models, the old seals can be used to drive in the new.

4. Grease the lips of the oil seals before installing on the fork tubes. After installing the slider on the fork tube, check that it can move smoothly up and down.

5. When installing the fork tubes in the triple clamps, ensure that the top of the tubes are flush with the top surface of the upper triple clamp (except F5, F6, F7, and F8). On F5, F6, F7, and F8 models refer to "Steering Stem Position" in the following section.

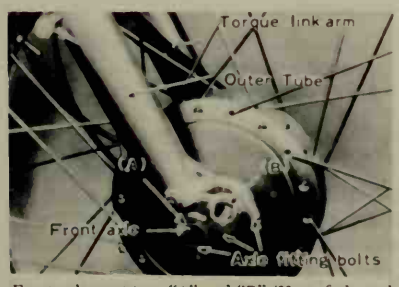
6. Refill each fork leg with the proper viscosity and quantity of oil.



Fork Adjustments

On F5, F7, and F8 models the front axle position, steering stem position, and the fork spring length are adjustable. On F6 models, the steering stem position is adjustable.

FRONT AXLE POSITION



A is the standard position.

Position B increases caster and reduces trail, resulting in faster steering and less stable operation at high speeds. This position is suitable for relatively low-speed

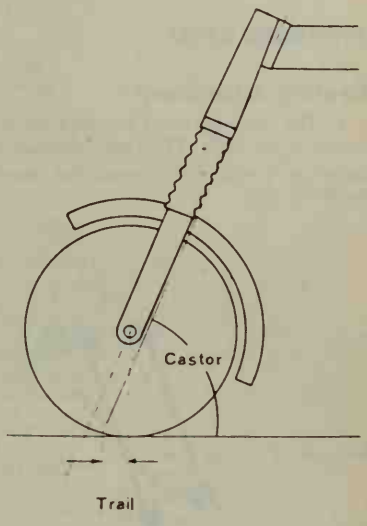
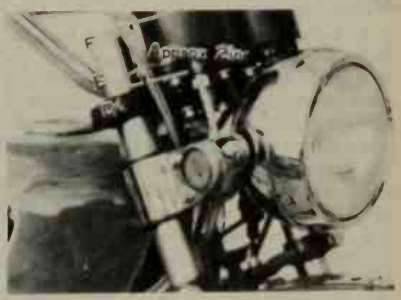
Front axle positions "A" and "B" (Hatta fork models)



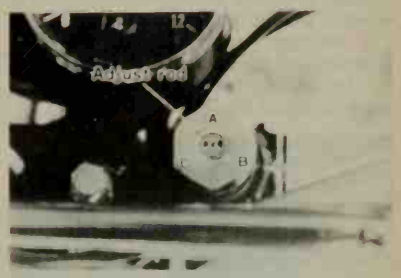
Front axle positions "A" and "C" (Hatta fork models)

operation where light, quick steering is an asset.



Position C is the most desirable setting for high-speed riding, where slow steering and stability are necessary.

In any case, do not forget to install the torque line and remember to make sure that the link bolts are secured.

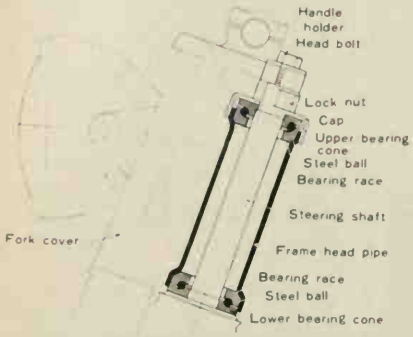


STEERING STEM POSITION

D is the standard position. E and F decrease caster and increase trail, resulting in greater stability at high speeds, and heavier steering. To adjust, loosen the four, triple clamp pinch-bolts, move both forks to the desired setting, and retighten the bolts.

Steering stem position (F5, F6, F7, F8)

Spring tension adjustment



FORK SPRING LENGTH

A is the standard setting for the fork springs. B and C positions progressively decrease the length of the spring, increasing the initial spring load and thus increasing spring strength. To adjust, simply remove the rubber cap and turn the adjuster rod to the desired position. Make sure that both springs are adjusted to the same position.

STEERING STEM

Bearing Adjustment

1. The steering stem bearings are uncaged ¼ in. balls. They are adjusted by means of a ring nut beneath the upper triple clamp.

Steering head components in cross-section

2. To check bearing adjustment, support the front wheel off the ground. Grasp the fork sliders.

3. Attempt to move the forks by pulling and pushing on the fork sliders. If play or movement can be felt at the lower triple clamp, the bearings are too loosely adjusted or worn.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged, or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The forks should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the balls are missing.

6. Bearings can be adjusted with a hammer and blunt punch or pin wrench on the adjuster nut after removing the upper triple clamp.

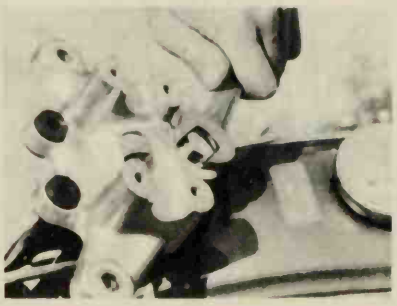
Adjusting the steering stem bearings

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that previously outlined. (Step 4.)

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Removal

1. Disconnect the cables, remove the electrical switches from the handlebars; unbolt and remove the handlebars from the motorcycle.



2. Unbolt the instruments from the upper triple clamp and lay them carefully aside. Unbolt the headlight from the brackets and allow it to hang by the wiring harness.

3. Remove the front wheel, fender, and remove both fork legs from the triple clamps.

4. Loosen the upper triple clamp pinch-bolt behind the large triple clamp nut (if fitted). Then remove the nut, and the large washer.

5. The upper triple clamp can now be removed. Tap upward on the underside of the triple clamp with a plastic mallet until it is free.

6. Remove the headlight brackets. Since the steering head ball bearings are uncaged, it is likely that some will drop

Removing the triple clamp bolt

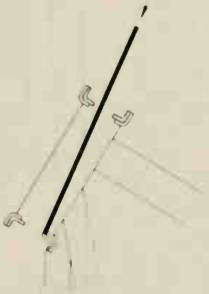
out of the races when the steering stem is lowered. Therefore, if the bearings are going to be reused, cover the ground beneath the assembly with a drop cloth.

7. With a hammer and punch, loosen the bearing adjuster nut until it can be turned by hand. Support the lower triple clamp with one hand while unscrewing the adjuster nut until it can be removed from the steering stem.

8. Remove the dust cover and the upper steering stem race.

9. Carefully lower the steering stem out of the frame lug. The top bearing balls should remain in the steering lug race. The bottom bearing balls should remain in the lower steering stem race.

Inspection and Installation



1. Before removing them, note the number of balls fitted to each race. The number may be different for the top and bottom races.

2. Remove the balls and wash them in a suitable solvent. Clean off the bearing races as well.

3. Inspect the bearing balls for rust, pitting, indentations, flat spots, or cracks. Rather than replacing individual damaged balls, both ball sets should be replaced, and the races as well.

4. The bearing race surfaces should be free of rust or corrosion, and smooth. Run your finger around the races. Any indented marks, ripples, or wear would indicate replacement of the races. If this is necessary, replace the balls as well.

5. The bearing races in the steering lug are removed with a hammer and punch. Installation should be made with a block of wood and a hammer to avoid damaging the races. The bearing race on

Remove the frame races with a long punch

the steering stem may have to be removed with a hammer and chisel.

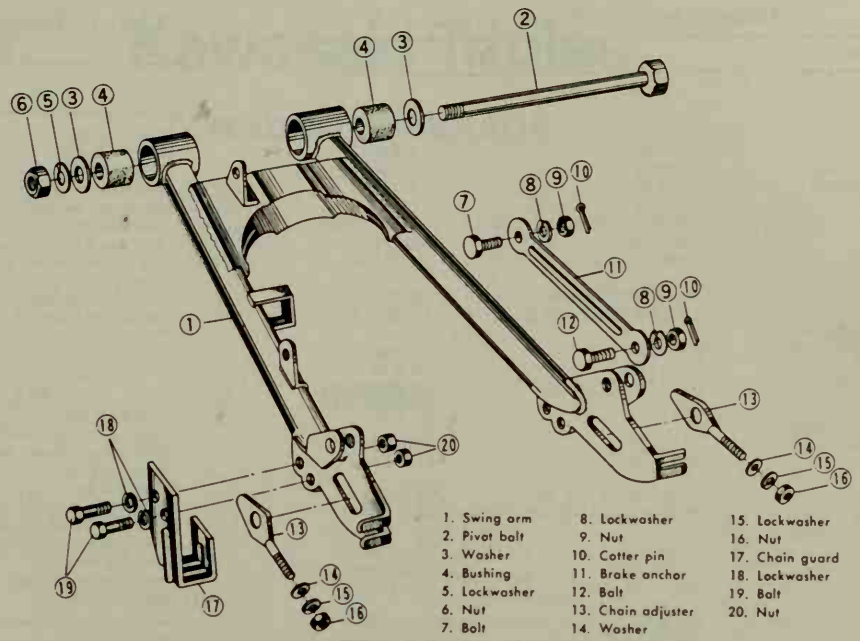
6. To install, put a thick layer of bearing grease on the top frame lug race and on the lower steering stem race. Embed the bearings in the grease, ensuring that the correct number of balls are fitted. Install the steering stem replacing the top race, dust cover, and adjuster nut. Tighten the nut until slight resistance is felt, then adjust it so the steering stem will fall to either side of its own weight when released from a few degrees from the centered position.

7. Reassemble the rest of the front end in the reverse of the removal procedure. Check bearing adjustment as described above

SWING ARM

The swing arm is mounted by means of bushings which tend to wear after many miles. The rate of wear will increase if the machine is used over rough terrain. For street machines, Kawasaki recommends replacement of the swing arm bushings every 6,000 miles. However, if a check of the bushings reveals that wear is minimal, this interval can be extended.

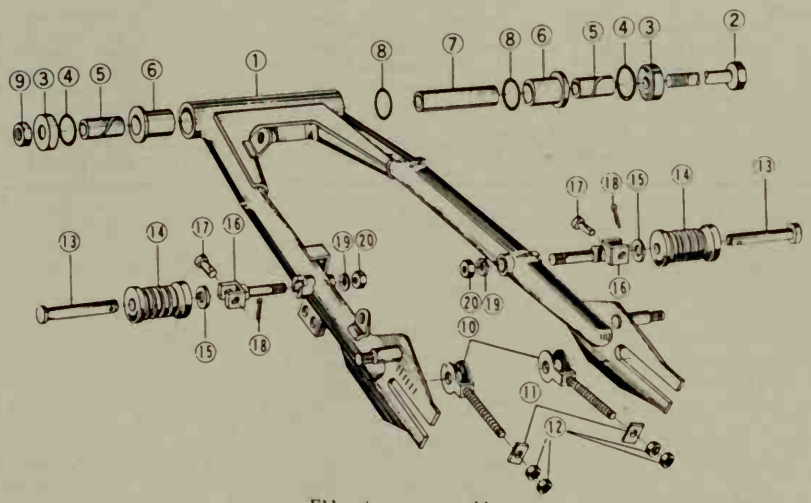
Inspection



1. To check the condition of the swing arm bushings, remove the rear wheel and sprocket and unbolt the lower shock absorber mounts.

2. Check for play by grasping the end of the swing arm firmly and attempting to move it from side-to-side. Play should be nil. If there is any, the swing arm should be removed and the bushings replaced.

3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced or fixed.



4. Check that the rear wheel mounting plates are parallel.

The swing arm is most likely to be damaged if the machine is operated for

any length of time with a broken or otherwise defective shock absorber.

Removal and Installation

1. Remove the rear wheel, sprocket hub, and chain guard. Unbolt the shock absorbers from the swing arm.

2. Remove the swing arm pivot shaft nut. Push or tap out the shaft; turn the swing arm sideways, and remove it from the machine.

3. Remove the dust covers from the ends of the swing arm tube if fitted. Note the location and number of any shims beneath the dust covers.

4. Remove the bushings, tapping them out with a long punch and hammer if necessary. Remove the spacer. Once bushings are removed, they should be replaced. Check the shaft for wear and replace it if there is any evident.

5. Lubricate new bushings with a good chassis grease. Press in one bushing, refit the spacer (if fitted), and install the other bushing.

6. Install the swing arm on the machine. After tightening the swing arm pivot shaft nut, move the swing arm up and down to ensure that movement is smooth and effortless.

REAR SHOCK ABSORBERS

1. Shock absorbers are sealed units which cannot be disassembled. If defective, they must be replaced.

2. If a shock leaks oil or is damaged in an accident (such as bent shaft, dented body, etc.), replace it.

3. To check a shock which is removed from the machine, place the bottom end on the ground and use the weight of your body to compress it as much as possible. Release the shock and note the rebound behavior. If the shock returns quickly at first, then slowly returns to the normal length, it is serviceable. If it returns to its normal length all at once, it should be replaced. Note that shock absorbers should always be replaced in pairs.

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION

Engine

The crankshaft bearings, cylinders, and pistons are lubricated by the Kawasaki Superlube (250–400cc) or Injectolube (500 and 750cc) oil injection system.

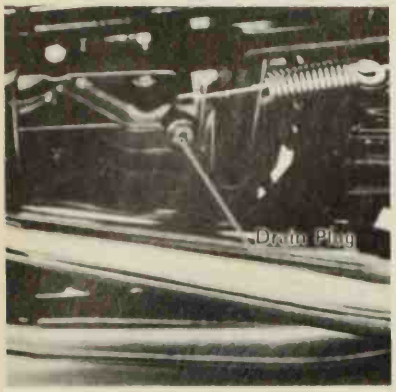
The system does not require maintenance except for a periodic check on the oil pump cable adjustment provided that the oil tank is kept full of oil. Any good quality injected two-stroke oil recommended for air-cooled engines may be used in the oil tank.

NOTE: *If the tank ever runs out of oil, or if the feed line is disconnected for any reason, it will be necessary to bleed the system before operating the motorcycle. Refer to the "Lubrication System" for procedures.*

Transmission

The transmission and clutch are lubricated by an oil bath. The correct amount and grade of oil recommended for your model is listed in the "Maintenance Data" chart.

CAUTION: *SAE 10W30 or SAE 10W40 oil or ATF is recommended. However, this does not mean that the two can be mixed. Either one or the other should be used exclusively. If it is desired to change from one to the other the transmission must be flushed clean first.*



CHECKING OIL

1. The machine should be on the center stand, preferably on a level surface when checking the transmission oil level.
2. The oil level should be checked with the engine warm.
3. A dipstick is provided in the rear of the right crankcase cover. To check the oil level unscrew it and wipe it off. Reinsert, screwing the dipstick cap in. The oil level should be between the maximum and minimum marks on the dipstick. If the level is too low, add oil until the level is correct. Do not overfill. Let the oil distribute itself for a minute or so, then recheck the level.

CHANGING OIL

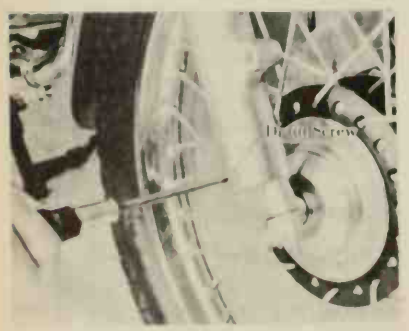
The transmission oil should be changed at least every 2,000 miles after break-in.

1. Oil should be changed when the engine is at or close to operating temperature.
2. The machine should be on the center stand and parked on a level surface.
3. Remove the dipstick.
4. Remove the drain plug and allow the oil to drain off for several moments.
5. Check the condition of the drain

Transmission drain plug location

plug gasket. Replace with a new one if damaged or cracked. Refit the drain plug and tighten firmly. Torque it to 36–52 ft lbs.

6. Fill the transmission with the correct type and quantity of oil. Capacities are given in the "Maintenance Data" chart. After filling, allow a moment or two for the oil to distribute itself, then check the level with the dipstick.



NOTE: *The use of oil additives is not recommended, since these may cause clutch slippage.*

Front Forks

1. SAE 10W oil is recommended for the front forks. If slightly stiffer damping characteristics are desired use SAE 20W. If softer damping is needed use SAE 5W.

2. Fork oil should be changed every 4,000 miles.

3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain into a suitable container; pump the slider up and down several times. After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit and tighten the drain plug.

Fork drain screw (H2 shown)

4. Repeat the procedure with the other fork leg.

5. Remove the fork filler caps from the top of each fork leg. The handlebar holders may have to be removed and the bars pulled back to allow access to the filler caps. Loosening the triple clamp pinch-bolts may make removal easier.

Removing the fork filler caps

6. Add the correct quantity and viscosity of oil to each fork leg. Capacities for each model are giving in the "Maintenance Data" chart.

Chassis Lubrication

1. Wheel and steering head bearings are lubricated with bearing grease. This should be accomplished every 4,000 miles. Refer to the "Chassis" section for procedures.

SERVICE CHECKS AND ADJUSTMENTS

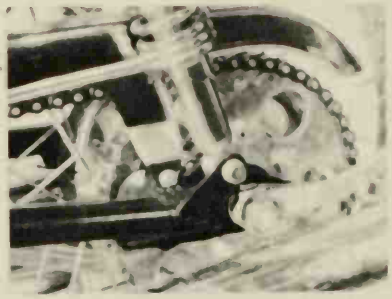
Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

2. *Before* checking or adjusting the chain slack, the following conditions should be met:

a. The machine should be off the center stand, and with a rider sitting on the seat;

b. The chain should be clean and well lubricated;



c. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points.

If a tight spot exists, the chain should be adjusted to the prescribed free-play at the tight spot.

3. To adjust the chain, first back off the rear brake adjuster nut if a rod-operated brake is fitted.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the sprocket hub securing nut (if fitted). Loosen the locknut on each adjuster bolt.

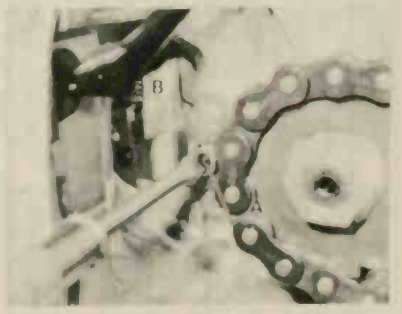
5. Turn each of the adjuster bolts in by equal amount until chain tension is approximately correct.

Loosening the axle nut

6. Check wheel alignment by means of the adjusting marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

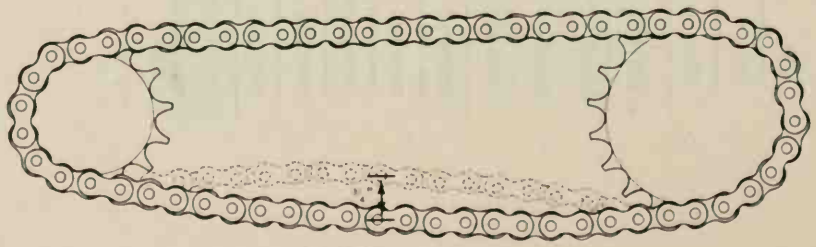
7. Tighten the sprocket nut and the axle nut and check the chain tension. Correct it if necessary. After adjustment is correct, torque the axle nut to 42–50 ft lbs. Fit a new cotter pin. Tighten the adjuster locknuts. Readjust the rear brake.

Clutch



Two adjustments are made to the clutch: cable adjustment and the pushrod adjustment. Usually, the pushrod need not be adjusted unless the clutch malfunctions. Cable adjustment must always be maintained at the proper specification.

To adjust the clutch:

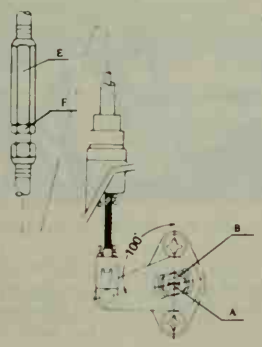


1. Loosen the clutch cable adjuster nut at the handlebar and screw in the adjuster to give a gap of 5–6 mm (0.20–0.24 in.) between the end of the adjuster and the locknut.

2. Loosen the locknut on the adjusting screw at the clutch release mechanism, and back the adjusting screw out 3 or 4 turns.

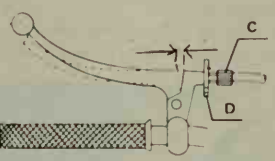
3. Turn the cable adjuster at the middle of the cable or on the engine cover in or

Adjusting the clutch: A, adjusting screw; B, locknut



Measuring chain free-play

out until the centerline of the release lever is at a 100° angle from vertical.

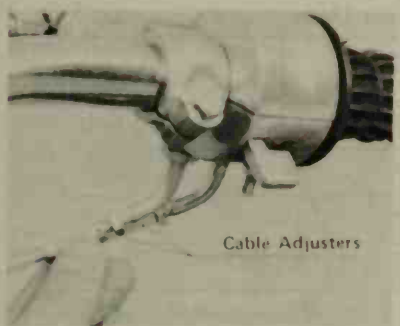


4. Screw the adjusting screw in until a resistance is felt, then tighten the locknut.

5. Using the cable adjuster on the handlebar, adjust the free-play of the cable until the hand lever can be moved 1/16–1/8 (2–3 mm) before the clutch starts to disengage.

Use the cable adjuster (E) to position clutch release lever as shown

6. The adjuster at the hand lever is used for minor adjustments and to maintain the cable free-play at the proper amount while riding.

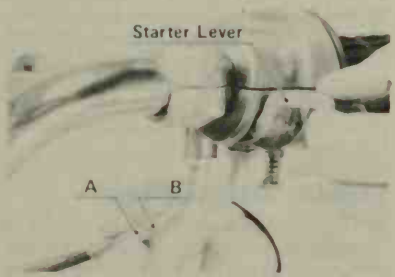


Clutch lever free-play is measured between the hand lever and the lever holder

Throttle Cables

1. Using the adjuster at the twist-grip adjust the cable so that the twist-grip can be rotated 5°–10° before the throttle slides start to open.

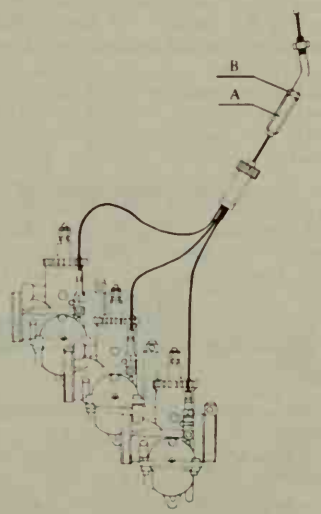
2. For other adjustments to the cables, refer to "Tune-Up."



Throttle cable twist grip and starter lever adjusters

Starter Cable Adjustment

1. Hold the starter lever in the closed position, and pull up and down on the cable sheath at each carburetor while turning the adjuster in or out until you can move the sheath 1–2 mm (0.04–0.08 in.) then tighten the locknut.



Adjusting the starter lever cable: adjuster, C; locknut, D

Starter lever handlebar adjuster

2. Using the adjuster at the twist-grip, set the starter cable free-play for 3–4 mm (0.12–0.16 in.)

Starter lever cables and handlebar adjuster (A and B)

Oil Pump Adjustment

1. The oil pump should be adjusted after the throttle cables. Refer to "Tune-Up."

2. The oil pump lever must start to move at the same time the throttle slides start to open.

3. Use the cable adjuster so that the marks on the oil pump control lever and the lever stopper are aligned at zero throttle opening.

Adjust the oil pump cable so that the marks align (HI shown)

Brakes

FRONT DISC

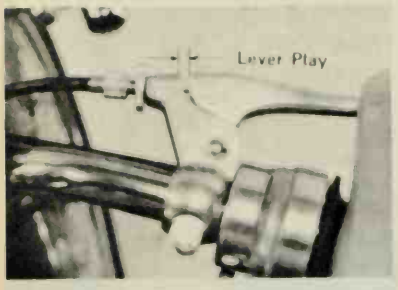
1. The brake lever is fitted with an adjusting screw on some models. The lever should have 5 mm (3/16 in.) of free-play, measured at the tip of the lever. To adjust, loosen the locknut and turn the adjusting screw in or out. Then tighten the locknut.

Adjusting disc brake lever free-play

2. Maintain the brake fluid level in the master cylinder at the level line inscribed on the inside of the master cylinder. Although the fluid level may drop slightly as the pads wear, this drop should not be significant.

Maintain brake fluid level at the marked line

3. Pads should be checked periodically for wear. Replace them when worn to or near the red limit line. Refer to "Chassis" for pad replacement procedures.



4. The brake hoses should be checked for seepage or abrasion damage often,

and should be replaced if they show wear or leakage of any kind. Make sure that the lines touch the frame or forks at the mounting points only.

5. Every 8,000 miles or 1 year, the brake system should be flushed and refilled with fresh fluid. Refer to "Chassis" for procedures.

FRONT DRUM

1. Use the cable adjuster on the cable end to allow about ¼ in. (6 mm) of brake handlebar lever free-play before the shoes contact the drum. This free-play is to be measured between the lever and the lever holder.

Adjust the brake cable so that the correct amount of play is available before the linings contact the drum

2. This free-play can be maintained as the shoes wear by using the adjuster at the handlebar lever.

3. The linkage of twin-leading shoe front brakes ordinarily does not need adjustment. If the backing plate has been disassembled, or adjustment is felt to be necessary because of weak brakes, proceed as follows:

a. Raise the front wheel off the ground so that the wheel can spin freely;

Adjusting the brake cam connecting rod

b. Loosen the locknut on the connecting rod and turn the connecting rod down one turn so that the rear brake lever is moved to the rear, increasing the distance between the levers. This allows the front shoe to be adjusted without interference from the rear one;

c. Turn the cable adjuster in until the front shoe just begins to contact the drum;

d. Turn the connecting rod up, decreasing the distance between the levers, until the rear shoe just begins to contact the drum; the connecting rod will no longer turn easily. At this point both shoes should begin to contact the drum at the same time. Tighten the locknut;

e. Adjust the brake cable free-play as previously described.

REAR BRAKE

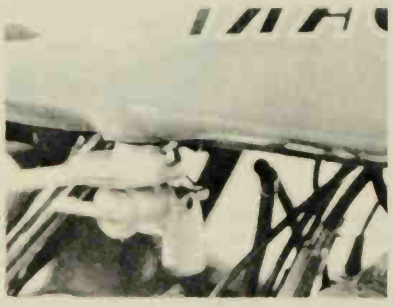
Use the adjusting nut on the end of the cable or rod so that the brake pedal has 1 in. of free-play before the linings contact the drum.

NOTE: *If the angle between the brake cable or rod and the lever on the brake plate exceeds 90° when the brake is applied with all adjustment taken up, the lining thickness should be checked.*

BRAKE LIGHT SWITCH

The switch should be checked for operation after the brake is adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the light switch up on the bracket allows the brake light to turn on sooner. Moving it down allows it to come on later. Generally, the brake light should come on just as the linings contact the drum.

Steering Stem Bearings



The steering stem bearings should be checked periodically and adjusted if necessary. Refer to the "Chassis."

FUEL SYSTEM

1. Fuel system maintenance involves cleaning the petcock and filter, cleaning or replacing the air cleaner, and cleaning the carburetors.

2. The carburetors should be removed, disassembled, and cleaned every 4,000 miles. The procedures are outlined in "Fuel Systems."

3. The petcock should be serviced every 2,000 miles. On H-series and newer 250–400cc, shut the fuel off, then unscrew and remove the petcock sediment bowl. Take out the fuel filter screen. On older S-series, disconnect the fuel lines at the carburetor and turn the petcock to "R" to drain the fuel tank. Unscrew the nut to remove the petcock. Clean the parts in solvent and install. Check for leaks.

Removing the petcock (standard type)

4. The air cleaner should be serviced or replaced every 2–3,000 miles, depending on conditions. If the air cleaner is the paper type, it should be kept free of water, solvents, etc.

5. To remove the air cleaner element:

250–400cc: remove the left sidecover and loosen the thumb screw on the air cleaner housing. Pull out the air cleaner housing along with the element. Remove the two screws which secure the element to the housing.

500cc: loosen the clamp screws securing the air cleaner hose to each carburetor

Removing the air cleaner (S-series)

Maintenance Data

Model	Fuel Tank Capacity (gal)	Oil Tank Capacity (qt)	Transmission Oil Capacity (qt)	Fork Oil① Capacity (cc/oz)	Tire Pressure (psi) Front/Rear
250	3.7	1.6	1.16	210/7.1	24/31
350	3.7	1.6	1.16	210/7.1	24/31
S3	3.7	1.6	1.16	155/5.3	24/31
KH400	3.7	1.6	1.16	141–149/4.8–5.0	25/28
H1/A-D	4.0	2.5	②	③	26/31
H1-E/F, KH500	4.2	2.5	1.3	170/5.6	26/31
H2	4.5	2.1	1.5	160/5.5	26/31
H2-B/C	4.5	2.1	1.5	175/5.9	26/31

③ Front drum: 230/7.8
Front disc: 160/5.5

and the clamp screw at the air cleaner housing, and remove the hose assembly. Remove the left-side carburetor after loosening the clamp screw. Remove the air cleaner mounting screw and remove the housing and element together through the left-side of the frame.

750: remove the left sidecover. Remove the rubber silencer beneath the seat. Loosen the air hose clamp screw on the air cleaner housing. Remove the housing mounting screw. Remove the front mounting bracket for the left sidecover. Push the air hose out of the way and remove the air cleaner and housing complete from the left-side of the frame.

6. Inspect the condition of the air cleaner element and replace it if torn or otherwise damaged. The sponge gasket must also be in good condition. If damaged, the element must be replaced.

Wash the element in pure gasoline and blow it dry. The elements used on these motorcycles are the dry-type, and should therefore be kept free of oil, oily solvents, etc.

On the 750, clean the felt part of the air cleaner in solvent, and apply a small amount of oil to the felt portion only. Keep the oil away from the element. Glue the felt portion on securely if it is loose.

Periodic Maintenance①

Daily (before each ride)
- Check lighting equipment and horn operation
- Check operation and adjustment of the brakes
- Tire condition
- Chain tension
- Cable adjustments
- Oil injection tank level

Weekly
- Transmission oil level
- Tire pressure (cold)
- Spoke tension
- Battery electrolyte level
- Chain condition
- Critical nuts and bolts

Monthly
- Trickle charge stored battery

Every 200 miles
- Lubricate chain

Every 2000 miles
- Change transmission oil
- Remove, clean and lubricate chain
- Lubricate control and instrument cables
- Check oil pump adjustment
- Clean fuel petcock
- Check brake fluid level (disc brake)
- Clean and gap spark plugs
- Clean points and check timing
- Clean or replace air filter
- Adjust brakes
- Decarbonize engine and exhaust system

Every 4000 miles
- Change fork oil
- Pack wheel and steering head bearings
- Check brake linings
- Check sprocket condition
- Grease speedometer drive mechanism
- Clean carburetors
- Replace spark plugs

Every 8000 miles
- Flush hydraulic disc brake system

① Based on normal usage after break-in is complete

Recommended Lubricants

Oil Tank
- Any high quality two-stroke motorcycle oil for air-cooled engines

Transmission
- SAE 10W30, "SE"
- SAE 10W40, "SE"
- ATF
- SAE 30 (summer)
- SAE 20 (winter)

Forks
- SAE 10
- SAE 20
- SAE 5W

Drive Chain
- Any high quality chain lube specifically developed for motorcycle drive chains

Wheel and Steering Head Bearings
- Lithium or moly-based bearing grease

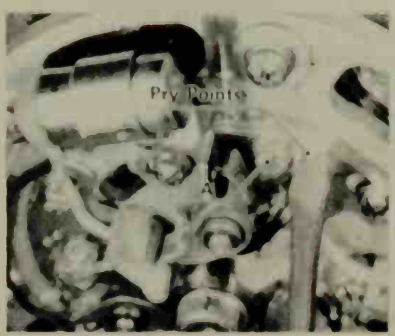
Cables
- Light motor oil
- Graphite-based lubricant
- Molybdenum disulphide-based lubricant

Grease Fittings
- Chassis grease

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information."*

CONTACT BREAKER POINTS



Location

Breaker points are mounted on a plate beneath the cover on the left-side of the engine. The cover is secured by two screws.

Gapping

ALL BREAKER POINT MODELS

Points should be filed (if necessary) and cleaned before gapping.

Loosen screw A and use a screwdriver at the pry point to adjust the gap

1. The breaker point set is secured to its plate by a single screw which is used to adjust the gap. This is not to be confused with the breaker point mounting screws which are used to adjust the ignition timing. A small pry slot for a thin screwdriver blade is also provided.

2. Turn the engine over slowly until one of the three sets of points is fully open. Check the gap for that set of points with the proper feeler gauge. Correct point gap for all models is 0.3–0.4 mm (0.12–0.16 in.).

3. If adjustment is needed, loosen the securing screw ("A" in the accompanying illustration), just enough to allow the gap to be varied, and increase or decrease the point gap with the aid of a small screwdriver applied to the pry slot.

4. Tighten the screw and recheck the gap. Note that the gap may change slightly when the screw is tightened.

5. Repeat the procedure with the two remaining point sets. Try to get the gaps of all three sets as close to one another as possible. That is, the feeler gauge blade should have the same amount of drag in all three point sets.

Replacement

ALL MODELS

1. Breaker points must always be replaced in sets. The contact surfaces of new points should be cleaned with a non-oily solvent to remove any preservative which may be present.

2. Loosen the breaker point terminal nut, disconnect the primary wire, remove the point securing screw, and remove the old point set.

3. Install the new set of points; connect the primary wire, and install the securing screw.

4. Repeat the procedure with the other two point sets. Set the gap on all three point sets and check the ignition timing.

Lubrication

1. A small dab of grease (high melting point is preferred) should be applied to each lubricating felt pad (there are three pads) so that the pad can distribute it onto the breaker cam. Be sure that each pad is adjusted so that it bears lightly on the breaker cam. A drop of light oil should be applied to the points pivot.

2. In any case it is imperative that care be taken to keep the lubricant away from the point contact surfaces.

IGNITION TIMING

Breaker Point Ignition

250, 350, 400

1. Remove the spark plugs and the breaker point cover. Clean and gap all three point sets.

Loosen screws B and move the points with a screwdriver to adjust ignition timing (S-series and KH250)

2. An inspection window is provided on the breaker point mounting plate through which can be seen the timing marks engraved on the alternator rotor. The marks are labeled "L," "R," "C," for the three cylinders. There is a corresponding mark on the breaker plate. In addition, each set of points is labeled for its cylinder.

3. Hook up the ohmmeter or light to any set of points. Turn the engine over slowly in the normal direction of rotation (counterclockwise), until the rotor timing mark for that set of points comes into view.

4. The light or meter should react indicating that the points have opened as soon as the rotor mark aligns with the mark on the breaker plate. If this happens, the ignition timing for that cylinder is correct. If the meter or light reacts before the marks align, the timing for that cylinder is too advanced; if the meter or light reacts after the rotor mark passes the breaker plate mark, the timing is too retarded.

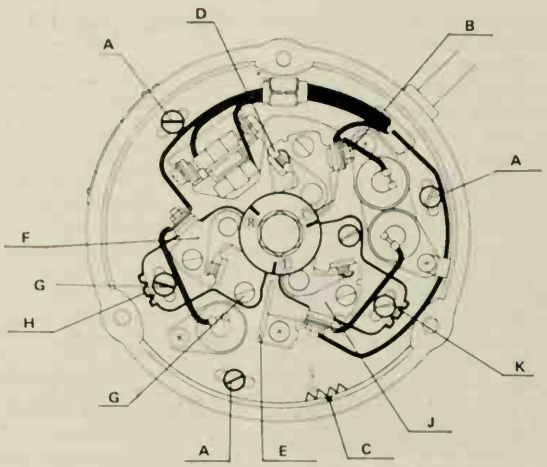
5. To adjust the timing, loosen the two point set mounting screws ("B" in the accompanying illustration), and use a small screwdriver at the pry points indicated to move the points to the left or right as necessary so that the points will begin to open as soon as the timing marks align. Secure the mounting screws and recheck the timing.

6. Repeat the procedure with the two remaining sets of points.

It can be seen that in order to correct advanced timing, the points should be moved in the direction of crankshaft rotation. To correct retarded timing, move the points opposite the direction of crank rotation. All three cylinders must be timed correctly before the procedure can be considered complete.

NOTE: *If any of the points cannot be moved far enough to correct the timing, excessive wear of the heel is probably the cause, and all three of the point sets should be replaced.*

H1



The ignition timing for the left cylinder *must* be set first. The points for the left cylinder are positioned at the top of the breaker mounting plate. It can be seen that these points are mounted directly on the breaker plate and rotating the entire plate is the only means of adjusting the timing for the left cylinder. This in turn will change the timing for the center and right cylinders.

Timing marks are provided on the rotor which can be used to set the timing under most circumstances. If the breaker plate has been removed from the engine or the timing pointer moved, timing must be reset with a dial indicator.

1. Remove the spark plugs and the breaker points cover. Clean and gap the three sets of points.

2. Attach the ohmmeter or test light to ground and to the terminal of the points for the left cylinder.

3. Slowly rotate the engine in the normal (counterclockwise) direction of rotation. At the instant that the "L" mark on the rotor aligns with the leading (left) edge of the timing pointer ("E" in the illustration), the meter or light should react indicating that the points have begun to open. If this is the case, the timing for the left cylinder is correctly adjusted. The other cylinders must still be checked, however.

Breaker point assembly (H1)

4. If the left cylinder timing was not correct, do not move the rotor; leave the marks aligned; loosen the three screws which secure the breaker plate to the engine. (These are lettered "A" in the illustration.) Using a small screwdriver at the pry point provided, rotate the breaker plate as necessary to correct the timing. Then tighten the screws.

CAUTION: *Do not move the rotor while the breaker plate screws are loose or timing may be lost.*

5. After tightening the breaker plate screws, move the pointer ("E") so that its leading edge is aligned with the "L" mark on the rotor. The position of the pointer will have changed when the breaker plate is moved.

6. Hook up the meter or test light to ground and to the terminal of the points for the right cylinder. Turn the crankshaft counterclockwise as before until the "R" mark on the rotor aligns with the leading edge of the timing pointer. The tester should indicate that the points have just begun to open when the marks align. If the points do not do so, loosen the two mounting screws for the right cylinder's points (lettered "G" in the illustration), and use a screwdriver and the pry point provided "H") to move the points in the direction necessary so that they will just begin to open when the timing marks are aligned. Tighten the mounting screws and recheck the timing.

7. Repeat the procedure (Step 6) for the remaining set of points (center cylinder).

If timing has been lost for any reason, or if a more accurate method of setting the timing is required, a dial indicator should be used.

1. After removing the spark plugs, cleaning and gapping the points, etc., fit the dial indicator into the left cylinder spark plug hole. Turn the engine over slowly until the gauge needle reaches a point and begins to reverse. This is piston top dead center. Turn the crankshaft a few degrees in either direction to confirm the finding, then place the piston at TDC and zero the gauge.

2. Turn the engine opposite to the normal direction of rotation (clockwise) until the dial gauge indicates about 4 mm (0.16 in.) before TDC. The breaker points for the left cylinder will be closed at this point.

3. Hook up the ohmmeter or test light to the points for the left cylinder. Check that they are closed. Slowly rotate the engine in the normal (counterclockwise) direction of rotation. When the dial gauge indicates that the piston is at the proper number of millimeters or inches before TDC, the points should begin to open as indicated by the reaction of the tester.

Proper timing specifications are as follows:

H1 (drum front brake)	0.136 in. (3.45 mm) (25°) BTDC
H1 (disc front brake)	0.088 in. (2.23 mm) (20°) BTDC

4. If timing is not correct, loosen the three screws which secure the breaker plate to the engine, and use a screwdriver at the pry point provided to rotate the plate so that the points for the left cylinder start to open when the piston is properly positioned at the correct distance before TDC.

5. When correct timing of the left cylinder has been accomplished, and maintaining the left cylinder's piston at the timing specification given in Step 3, check the alignment of the rotor timing mark and the timing pointer. If the rotor mark is not aligned with the leading (left) edge of the pointer, move the *pointer* so that alignment is achieved. Do not move the rotor.

6. Timing of the right and center cylinders must still be accomplished. This can be done either with the dial gauge, or simply by aligning the rotor and pointer as outlined in the previous section.

CDI Ignition

KH400

1. Remove the left engine cover.
2. The mark on the magneto stator

Stator and crankcase marks aligned (KH400)

plate should be aligned with the crankcase mark.

3. If the marks are not aligned, remove the magneto flywheel, loosen the three stator plate screws, and rotate the plate so that the marks are in alignement.

4. Tighten the screws securely and install the flywheel.

5. Timing is checked with a strobe light.

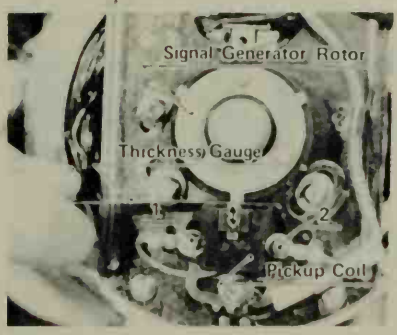
6. Connect the strobe light to the left cylinder.

7. Start and run the engine at 4,000 rpm. The timing mark on the flywheel should align with the crankcase mark at this engine speed.

8. If the marks do not align, rotate the stator plate as in Steps 3–4 above until alignment is achieved.

H1

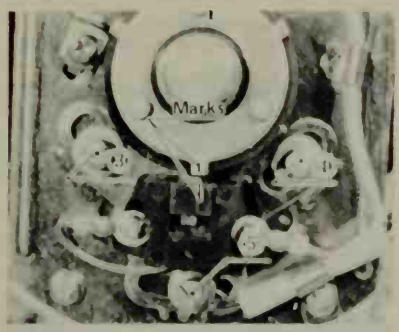
A dial gauge should be used to set the timing.



1. Remove the spark plugs, the rotor cover and the distributor cover.

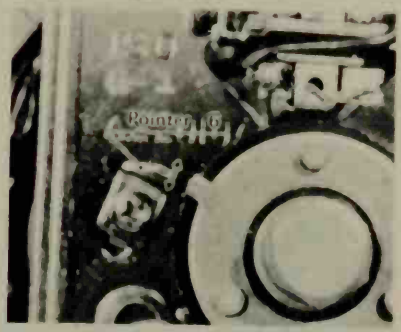
2. Place the right cylinder at top dead center, and check that the timing mark on the distributor plate is aligned with "T" mark on the engine case.

Line up the timing mark on the distributor plate with the "T" mark on the engine case (H1 battery-CDI)



3. Slowly rotate the crankshaft so that one of the magnetic projections of the signal generator rotor is aligned with the pickup coil. Check the gap between the projection and the coil with a feeler gauge. Proper gap is 0.4–0.6 mm (0.016–0.024 in.). If adjustment is necessary, loosen the two coil mounting screws (1 and 2 in the illustration) and move the coil so that the gap is correct.

Checking rotor-to-pickup coil gap

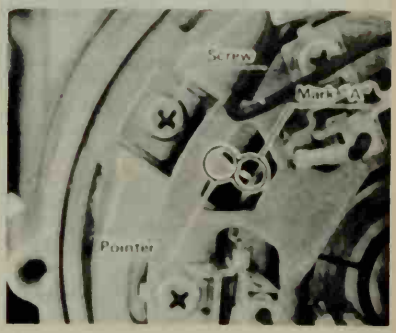


4. Fit the dial gauge into the left spark plug hole and position the piston at 0.136 in. (3.45 mm) before top dead center.

5. Check that the timing marks on the rotor and the top of the pickup coil are aligned as shown in the illustration. If they are not, loosen the three pickup coil adjusting screws (3, 4, and 5 in the illustration), and move the coil so that the marks align. Secure the screws.

With the piston properly positioned, line up the timing marks after loosening screws 3, 4, and 5

6. Check that the timing pointer (No. 6 in the illustration) aligns with the mark on the rotor as shown. If it does not, loosen the pointer screw, and move it so that alignment is achieved. Note that the piston must remain at the correct distance BTDC during this operation.



Timing pointer "6" can be used to check ignition timing after it is aligned with the rotor mark

NOTE: *Once this pointer is correctly aligned, it can be used to check the timing, or reset the timing whenever the pickup coil is removed.*

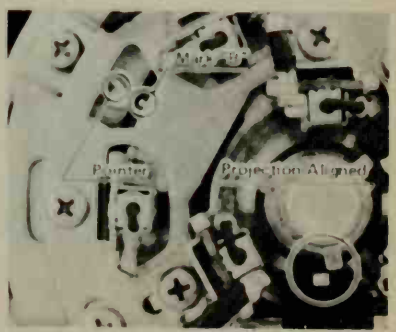
H1-E/F, KH500

The ignition system on the H1-E and following 500 models is somewhat different than the battery/CDI system found on early models.

1. Timing is checked with a strobe light. With the engine running at 4,000 rpm, and the strobe light connected to the left spark plug, the timing mark on the rotor ("A" in the illustration) should align with the stationary pointer.

The mark "A" should align with the pointer at 4000 rpm (H1-E, KH500)

2. If adjustment is necessary, proceed as follows:



3. Remove the left cylinder's spark plug and install a dial gauge.

4. Turn the engine over using a 13 mm wrench on the Signal Generator rotor bolt until the left cylinder is at TDC. Zero the gauge.

5. Turn the engine *clockwise* until the gauge indicates that the left piston is 2.4 mm (0.1157 in.) or 23° before TDC.

6. With the piston in this position, the mark on the rotor ("A" in the illustration) should align with the stationary timing pointer. If it does not, loosen the pointer securing screw, and move the *pointer* (not the rotor) so that they align.

7. Tighten the pointer screw. Turn the crankshaft slowly in the normal direction of rotation (counterclockwise) until the next timing mark appears ("B" in the illustration). Align this mark with the pointer. With these marks aligned, the trailing edge of one of the rotor projections must align with the edge of the pickup coil projection.

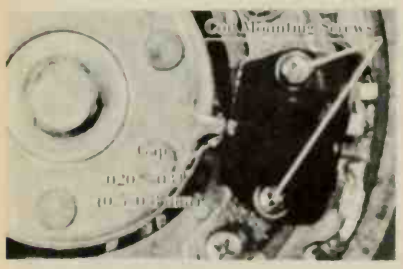
Mark "B" aligned with the pointer as trailing edge of rotor projection aligns with edge of the pickup coil projection (H1-E, KH500)

8. If it does not, loosen the three stator mounting plate screws, and rotate the plate so that alignment is obtained. Tighten the screws securely.

9. Turn the rotor clockwise a few degrees until the rotor projection and the pickup coil projection are directly in line.

Pickup coil/rotor projection gap H1-E/F, KH500

Measure the gap between them with a feeler gauge. It should be 0.5–0.8 mm (0.020–0.031 in.). If not within specification, loosen the two pickup coil screws and move the coil up or down until the gap is correct. Tighten the screws securely.



10. To check the timing, use a strobe light as outlined in Step 1. Mark "A" should align with the pointer at 4,000 rpm.

H2

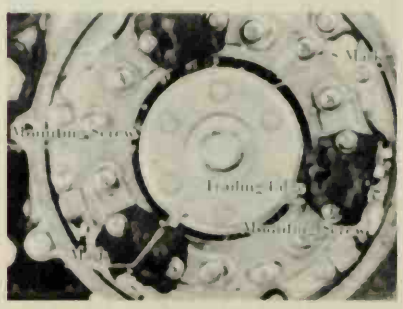
1. Timing can be checked with a standard automotive stroboscopic timing light if one is available. Connect the light to the left cylinder plug lead. Start the engine. At 4,000 rpm, the rotor "L" mark should line up with the timing pointer. If it does not, timing must be adjusted.

2. Timing for each cylinder is adjusted independently; therefore, use the strobe light to check the right and center cylinder timing as well.

3. Turn the engine over so that the magnetic projection of the rotor is aligned with any one of the pickup coils. Check the gap between the two. Correct gap should be 0.5–0.8 mm (0.020–0.031 in.). If adjustment is necessary, loosen the two coil mounting screws and move the coil so that the gap is correct. Then secure the screws. Repeat the procedure with the other two pickup coils.

Rotor/pickup coil gap (H2)

CAUTION: *The coils must be moved by hand only. Do not pry the coil toward or away from the rotor, as this risks breaking the coil housing.*



4. Insert a dial gauge into the left cylinder. Set the piston to 3.13 mm (0.123 in.) before top dead center.

5. Check that the timing pointer is aligned with the "L" mark on the rotor. If it is not, bend the pointer so that alignment is achieved.

Aligning the timing pointer (H2)

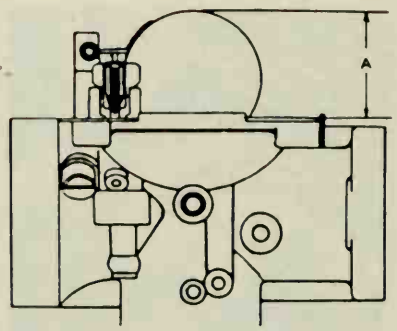
6. Turn the rotor slightly so that the "S" mark for the left cylinder aligns with the timing pointer. When this is done, note that the trailing edge of the rotor's magnetic projection should be aligned with the mark on the pickup coil for the left cylinder. If these marks are not aligned, loosen the two pickup coil mounting plate screws, and move the coil in the direction necessary to align the marks. When the rotor "S" mark is aligned with the timing pointer and the trailing edge of the magnetic projection is aligned with the mark on the pickup coil, the timing is correct for the left cylinder.

With the "S" mark aligned, the trailing edge of the rotor projection must align with the pickup coil mark. If adjustment is necessary, loosen the mounting screws and move the coil (H2)

7. Timing for the remaining two cylinders must be checked as well. Since the timing pointer was set correctly in Step 5, it is only necessary to align the "S" mark for the right and center cylinders with the timing pointer and check the alignment of the trailing edge of the rotor projection and the timing mark atop each pickup coil. If adjustment is necessary, loosen the pickup coil mounting plate screws and move the coil as necessary to effect timing.

8. After checking timing on all three cylinders, check dynamic timing with a strobe light.

CARBURETORS



Adjusting Float Level

EARLY MODELS

1. Remove the carburetors.

2. Turn the carburetor upside down, and remove the four float bowl screws carefully lifting off the float bowl.

3. Remove the float bowl gasket.

Float level "A" is the distance from the float bowl gasket surface (gasket removed) to the top of the float

4. Float level can be measured with a steel rule or a vernier caliper. Float level is defined as the distance from the float bowl gasket surface (gasket removed) to the top of the float, when the tang of the float arm is just touching the float needle.

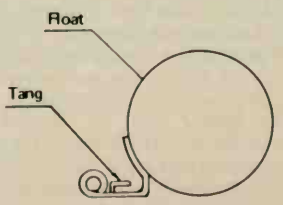
NOTE: *Lower the float down until the tang just contacts the float needle. Hold the float in this position, then measure the float level.*

5. Compare the value obtained with the correct specification for your machine. If the float level is too high or low, pull out the pin which holds the float in place, and bend the tang very slightly to correct the adjustment.

NOTE: *If float level is too high, bend the tang away from the carburetor body. If too low, bend it toward the carburetor body.*

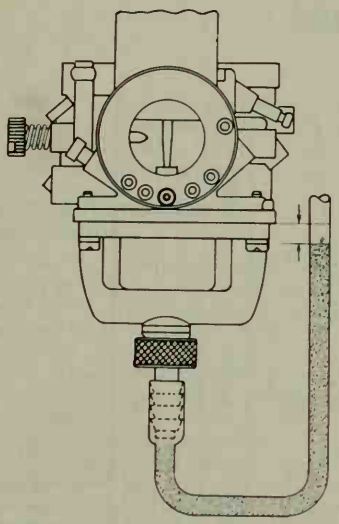
6. Refit the float and recheck the adjustment.

CAUTION: *Bend only the float tang to make an adjustment. Do not bend the float arms. The floats must be level. If the floats show different heights, the float assembly should be replaced. This indicates that the float assembly has been mishandled. It is very important that all three carburetors have the same float level.*



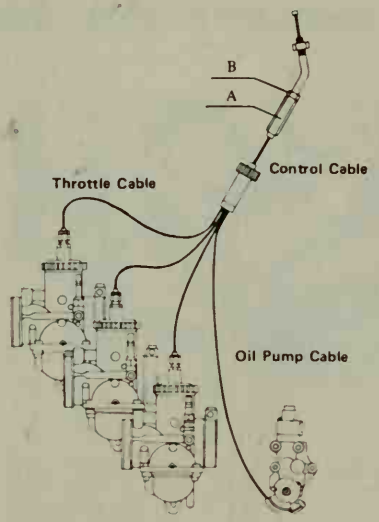
7. Float level will not be correct if the needle is worn or if there is foreign matter on the needle seat.

LATE MODELS



The following procedure may be used on later model machines provided that the special gauge is available. If it is not, check level as outlined for early models.

1. Remove the carburetor from the manifold with the feed line connected, but the fuel off.



2. Remove the float bowl and fit the special gauge (see illustration) in its place.

To adjust float/fuel level, bend the tang only

Fuel level is measured from the bottom of the carburetor body if the bowl fitting is available

Throttle cable linkage

3. Keep the carburetor vertical. Hold the plastic line against the body and turn on the fuel.

4. The gas in the line should come up to a point 2–4 mm (0.08–0.16 in.) below the float bowl mating surface on 500 and 750s. Proper level for 250 to 400 machines is 4–6 mm (0.16–0.24 in.).

Carburetor Synchronization

Carburetor synchronization includes adjustments to the throttle cables, the idle speed, and the idle mixture. Cable adjustments are necessary to ensure that all three throttle slides move together.

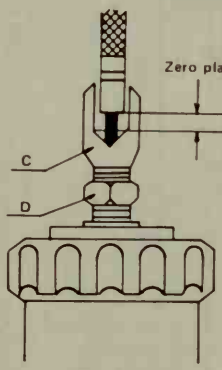
Before attempting adjustment, the following conditions should be met:

a. The tank should have a good supply of gasoline;

b. The carburetors must be vertically aligned, not tilted to one side or the other;

c. Carburetor clamp screws should be tight;

d. The engine should be at normal operating temperature.



A cable adjuster is fitted to the top of each carburetor and another at the twist-grip. One throttle cable runs from the twist-grip to a junction box. There, it is connected to the oil pump cable and three throttle cables which run to the carburetors. Therefore, each cable must be adjusted.

When reading the following, note that some carburetors have the throttle stop rod (idle adjustment) screw located on the carburetor cap, while on others it is a wheel on the side of the body.

1. Loosen the locknut on the twist-grip throttle cable adjuster, and turn the adjuster in to provide a good amount of free-play in the cable.

2. Turn the throttle stop screw of each carburetor *in* (if rod-type), or *out* (if wheel-type) until all three throttle slides are fully closed.

3. Using the cable adjuster atop each carburetor, adjust for zero play in each of the carburetor cables. This is done by loosening the adjuster locknut, lifting the cable out of the adjuster as far as possible without lifting the slide, and turning the adjuster out until it meets the cable sheath. Check that it is not possible to lift the cable out of the adjuster without lifting the slide as well. But take care that the cable adjuster is not turned out so far as to partially lift the slide. The slide must remain in the fully closed position. Be sure to tighten the adjuster locknut.

Use the adjuster "C" to effect zero play between the adjuster and the cable sheath

4. Turn the pilot air screw on each carburetor in until lightly seated, then back each one out the prescribed number of turns as indicated for your model in the "Tune-Up Specifications" chart.

Adjusting the pilot air screw (KH400 shown)

5. Start the engine, running it for a minute or so. Then turn the throttle stop screw on each carburetor in or out in small, equal increments until the lowest smooth idle speed is obtained. It is critical that the throttle stop screws be turned the same amount for each of the three carburetors.

Throttle stop screw (S2 shown)

Throttle stop screw (S1 shown)

6. Place your hands over the ends of each muffler and check for equal pressure. If the pressure here is not equal for all three cylinders, either one cylinder is leading the others (idle speed too high), or is dragging (idle speed too low). Make fine adjustments to that cylinder by adjusting the pilot air screw or the throttle stop screw. It should not be necessary to turn either adjustment screw more than a small amount to equalize the backpressure. If it is, there has either been a mistake in settings, or there is a mechanical defect in the fuel system or engine, or ignition system.

7. After synchronization is complete, turn each of the throttle stop screws in or out in small, equal increments, until the recommended idle speed is reached.

8. Turn the throttle twist-grip adjuster so that the twist-grip has 5–10° of free rotational movement before the throttle slides begin to lift.

9. Check the oil pump cable adjustment. Refer to "Maintenance."

A further check of slide synchronization can be accomplished after removing the air cleaner hoses from the carburetors. Turn the twist-grip slowly while observing the movement of the throttle slides. All three should begin to move at the same time. Turn the twist-grip until the cutouts in the slides just clear the upper portion of the carburetor bore. Slide a finger in along the upper surface of the bore to ensure that each cutout is just even with the top surface of the bore. All three slides must be in the

Checking throttle slide synchronization

Slide heights must be even as shown in the lower drawing

same position. If any one is too high or too low, use the cable adjusters atop each carburetor to effect adjustment. Allow the slides to close, and recheck cable adjustment.

NOTE: *After setting cable adjustments, turn the front forks slowly lock-to-lock with the engine idling. Any variation in idle speed as this is done would indicate that the throttle cable(s) are too tightly adjusted or are binding somewhere along the routing.*

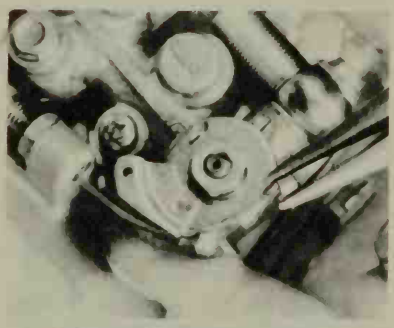
ENGINE AND TRANSMISSION

NOTE: *For engine component inspection techniques and procedures, refer to "Engine Rebuilding" under the General Information section.*

Engine Removal and Installation

Clean the engine thoroughly before removal to take away as much grease and road grime as possible. Be especially attentive to the cylinder base and the crankcase mating areas.

1. Warm the engine and drain off the transmission oil. Replace the drain plug hand-tight.
2. Remove the spark plugs.
3. Turn the fuel petcock to the "S" position (standard type petcock), disconnect the fuel lines from the carburetors and unbolt and remove the fuel tank.
4. Remove the complete exhaust system from the motorcycle.
5. Remove the three phillips head mounting screws from the oil pump cover and lift the cover up (500, 750) or remove it (250–400).
6. Unscrew the tachometer cable fitting and disconnect the cable from the engine.



Disconnecting the tach cable (S-series)

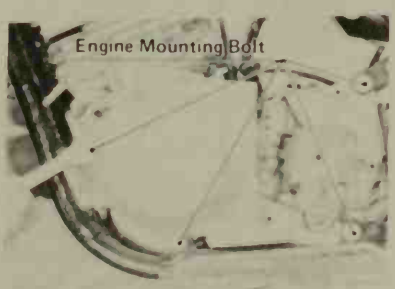
7. Remove the distributor cap (early H1 battery-CDI only).

Removing the distributor cap (H1 battery-CDI)

8. Remove the air cleaner connecting tubes.
9. Remove the carburetors after loosening the clamps which secure them to the intake manifold. Tie them out of the way with the cables attached.
10. Remove the shift lever pinch-bolt and remove the shift lever and the shift lever pivot bolt.

Disconnecting the oil pump cable

11. Disconnect the oil pump control cable from the oil pump control lever and cable holder.
12. Disconnect the oil tank delivery line at the pump. Plug the end of the line to prevent the oil tank from draining.



Plugging the oil delivery line

13. Remove the four phillips head screws from the countershaft sprocket cover and remove the cover.
14. Remove the masterlink (if fitted) from the drive chain. If no masterlink is fitted then loosen the rear axle nut and sprocket nut, loosen the chain adjusters and move the wheel forward and slip the chain off the countershaft sprocket.

NOTE: *If the sprocket is to be removed later, loosen the sprocket nut before disengaging the chain.*

15. Slacken the clutch cable; disconnect the cable from the clutch release mechanism after straightening the lever tongue, then disconnect the cable from the engine cover.
16. Disconnect the alternator leads from the main harness at the connectors under the seat.

Engine mounting bolts

17. Remove the engine mounting bolts and remove the engine from the frame.
18. Installation is basically the reverse of the removal procedure, but the following points should be noted:
19. Engine mounting bolts should be properly torqued. Refer to the "General Torque Specifications" chart.
20. Coat the threads of the engine case screws with anti-seize compound or a general purpose lubricant to prevent them from seizing in the engine cases. Install them with an impact driver.
21. Replace any worn or damaged exhaust pipe gaskets.
22. Make sure that all fuel and oil lines are properly seated and secured with circlips.
23. After refilling the transmission and bleeding the oil pump, check all points of adjustment: cables, chain, rear brake, ignition timing, carburetor synchronization, oil pump cable adjustment, etc.
24. Install the drive chain masterlink spring clip (if fitted) with the closed end facing the direction of rotation.
25. After starting the engine, check around the carburetor and air cleaner for air leaks.

TOP END

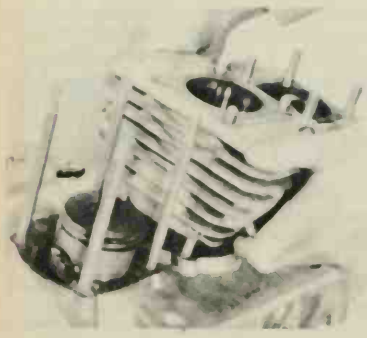
The components in the top end are the cylinder heads, cylinders, pistons, piston rings, wrist pins, and the connecting rod small end bearings. All of these can be removed for inspection and service with the engine in the frame. No special tools are needed to remove these components.

Cylinder Head, Cylinder and Piston

REMOVAL

Clean the engine thoroughly before beginning.

1. Remove the fuel tank and exhaust header pipes.
2. Loosen the carburetor connecting bands, and remove the carburetors from the intake manifolds.
3. Disconnect the spark plug leads and remove the spark plugs. Disconnect the oil lines at the cylinder on models so equipped.
4. Loosen the four cylinder head nuts from each cylinder ¼ turn at a time in an "X" pattern. When all of the nuts are

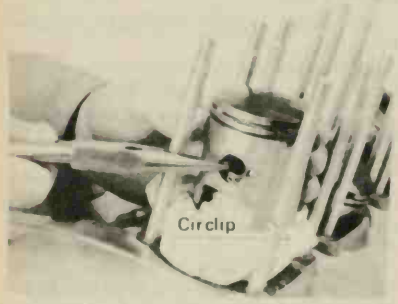


Removing the cylinder head

loose, remove them and their washers from the studs. Carefully lift off the cylinder head, and remove the head gasket beneath it as well.

NOTE: *If the cylinder head will not come off the cylinder, tap it at the bottom with a soft-faced mallet until it is free. Take care not to break the cooling fins.*

To remove the cylinder, place one of the outside pistons at top dead center.



5. Lift that cylinder up and off the studs. When the cylinder spigot clears the crankcases, insert a clean, lint-free rag between the cylinder and crankcases. This will catch any piece of broken ring which may drop out when the piston comes out of the cylinder bore. Continue lifting up the cylinder until the piston clears the bore, then place it in a safe place with the lower end up to await service.

Removing a cylinder

NOTE: *Pistons must be reinstalled into their proper cylinder; therefore, mark the position of each piston before removal.*

6. Remove the wrist pin circlips with needlenose pliers. The rag should remain in place while doing this to prevent one of the circlips from falling into the crankcase.

Removing a wrist pin circlip

IMPORTANT: *New circlips must be used on reassembly.*

Grasp the piston with one hand, and push out the wrist pin with a suitable drift. If the pin will not come out, the piston crown may be heated, evenly and gently, with a propane torch. If the pin still resists, it is advisable to use a special tool to remove it. This consists of a steel band or bands which fits around the piston while an attached screw device is used to push out the pin.

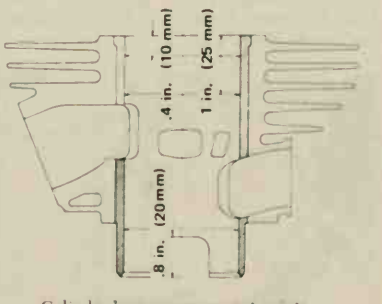
Removing the wrist pin

7. When the wrist pin is about ¾ in. out of the piston, grasp the exposed end with needlenose pliers, and pull it out until it is clear of the connecting rod. Remove the piston and small end needle bearing from the connecting rod.

CAUTION: *Never strike the wrist pin or attempt to use force to drive it out. The connecting rod may be bent in the attempt.*

Cylinder and Piston

INSPECTION

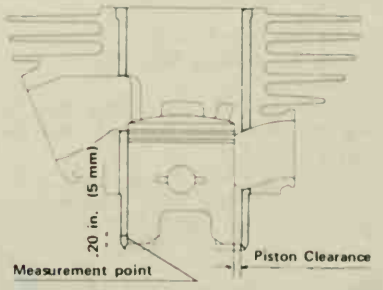


1. Inspect the surface of the cylinder walls for scoring or other damage. It is recommended that the cylinder be lightly honed.

2. After honing, inspect the cylinder walls again. If scores or scratches deeper than 0.001–0.002 in. (0.025–0.050 mm) remain in the walls, the cylinder should be rebored and the next oversize piston fitted.

3. Make a visual inspection of the piston. It should be free of scoring or signs of extreme wear. If any damage has occurred, it may be possible to save the piston by polishing the damaged area with an oilstone, or with #400 grit sandpaper or crocus cloth. However, if score marks are deeper than 0.002–0.003 in. (0.050–0.075 mm), or if the scored area is wider than 0.5 in., it is recommended that the piston be replaced.

If the piston is sanded, do so to yield a cross-hatch pattern.



4. Check that the piston ring locating pins are not excessively worn. If they are, the piston should be replaced. Check the fit of the wrist pin in the piston; if the wrist pin is a very loose fit, the piston and wrist pin should be replaced.

Cylinder bore measurement points

5. Measure the cylinder bore diameter in three locations, as shown, in directions both parallel and perpendicular to the crankshaft (six measurements). If any of the measurements are greater than the service limit given at the end of this section, or if any two measurements vary by more than 0.05 mm (0.002 in.), the cylinder should either be bored to an oversize or replaced. This checks cylinder wear, taper, and out-of-round. Oversized pistons are available in two sizes: 0.5 mm and 1.0 mm.

6. Measure the piston diameter at a point 5 mm (0.2 in.) from the bottom of the skirt and perpendicular to the wrist pin. Then measure the cylinder diameter at a point 5 mm (0.2 in.) up from the bottom of the cylinder also perpendicular to the wrist pin. The difference between the two measurements is the piston-to-cylinder clearance. If the clearance is greater than the service limit given at the end of the section, a new piston should be fitted. If this does not bring the clearance into specification, the cylinder will have to be bored and an oversize piston fitted.

Piston-to-cylinder clearance

7. After boring the cylinder, or whenever the rings are replaced, the cylinder should be honed so that a cross-hatched finish is produced. Also, it is important that the edges of the ports be bevelled slightly. This can be done with some emery cloth.

8. Be sure that the piston rings are free in the grooves, and that the grooves have not been closed up by having metal pushed into them as might occur if the piston has seized. The ring grooves should be cleaned of any carbon build-up after the rings have been removed.

9. With the rings installed in their grooves, measure the piston ring groove side clearance with a feeler gauge. If the clearance is greater than the service limit given at the end of this section, replace the rings as a set. If fitting new rings does not bring the side clearance into the proper tolerance, replace the piston as well.

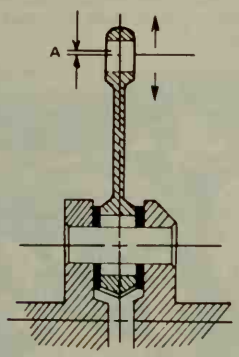
If the side clearance is not sufficient, it is probable that the piston has suffered seizure damage (metal being pushed into the ring grooves). In this case, the piston must be replaced.

10. Remove the rings from the piston by carefully spreading the end-gap with your thumbs and moving the part of the ring opposite the end-gap off the piston. Place each ring on a flat surface such as a piece of plate glass to check for warpage. If either ring is warped or twisted, replace the rings as a set.

11. Assuming that the cylinder bore is

not excessively worn, measure the end-gap for both piston rings. Insert each ring into the bore about 5 mm (0.2 in.) from the bottom of the cylinder. Push the ring into the bore using the piston; this will ensure that the ring is perpendicular to the cylinder wall.

Check that the ring is contacting the cylinder wall at all points. Place the cylinder with the ring in it on a white paper under strong light. If you can see the paper between the ring and the cylinder wall, replace the rings, or check the cylinder bore diameter.



Measure the end-gap with a feeler gauge. If the end-gap of any ring is greater than the service limit given at the end of this section, replace all rings.

New rings should also be checked in this manner before installation. If the end-gap of a new ring is too small, use a fine file to remove as much material from the ring ends as necessary.

NOTE: *Be sure to check the gap often during this operation as it is easy to remove too much metal.*

12. Make a visual inspection of the small end bearing. If the rollers are worn, cracked, bind in the cage, are blued from overheating, or if the bearing cage is damaged, replace the bearing.

13. Check the bore in the connecting rod small end for scoring. If replacement of the rod is necessary, refer to the following "Crankshaft Assembly" section. Check the small end bearing for play. This is done by installing the bearing and wrist pin in the connecting rod and feeling for up-and-down play between the wrist pin and connecting rod. If play is noticeable, replace the bearing.

Check the con rod for vertical play which would indicate a worn big end bearing

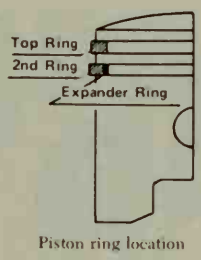
14. If the wrist pin shows any blueing, which is indicative of overheating or lack of lubricant, it and the needle bearing should be replaced.

15. Check the connecting rod for radial (up-and-down) play on the crankpin. There must be absolutely none. If any play is evident, this indicates a badly worn big end bearing. Procedures for measuring the con rod radial and axial clearance and crankshaft service steps are given under "Crankshaft Assembly," which follows.

16. The connecting rod should be checked to ensure that it is not bent. This can be done without the need for special tools by installing the piston, minus the piston rings, onto the connecting rod, and then installing the cylinder.

The piston should be seen to be in the center of the bore. If the piston is moved to either side, it should return to the center by itself.

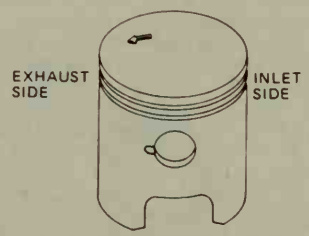
If the piston is contacting one side of the cylinder and not the other, the connecting rod is probably bent.



Cylinder Head, Cylinder and Piston

INSTALLATION

1. Refit the piston rings to the piston; note that the top ring has a chrome outside edge and is also chamfered while the bottom ring is un-chamfered. If the bottom ring has a expander behind it, install this into the ring groove first. Install the rings, beginning with the bottom ring, by spreading them slightly and sliding them down over the piston and into their respective grooves. The rings must be installed with the number and letter facing up and the end-gap over the locating pins in the grooves.



Ring expander

Piston ring location

2. Fit one of the *new* wrist pin circlips into the far side of the piston; the gap in the circlip should face either up or down. Install the wrist pin into the near side of the piston so that about ⅛ in. of the wrist pin is visible protruding from the inside of the piston. The wrist pin should be a push-fit, but gentle heat may be applied to facilitate installation as on removal.

The arrow on the piston crown should point toward the exhaust port

3. Install the small end bearing into the connecting rod. Lubricate it with two-stroke oil.

4. Place the piston over the connecting rod with the arrow stamped on the top of the piston pointing to the exhaust side of the engine.

5. Carefully line up the wrist pin with the connecting rod small end bearing, and push the wrist pin through until it is centered between the circlip grooves.

6. Install a new circlip into the groove in the near side of the piston. Be sure that both circlips are firmly seated in their grooves with the gap in the circlip facing either up or down.

Make sure that the gap in the circlip is positioned downward and that the clip is firmly seated in its groove

7. Lightly lubricate the piston rings and the piston skirt with two-stroke oil.

8. Install a new cylinder base gasket, making sure that it is installed correctly.

9. Place the piston at top dead center. Align the piston rings so that the ring ends are directly over the locating pins.

10. Take up the cylinder, make sure that the cylinder walls are lightly coated with oil and fit the cylinder on the crankcase studs.

11. Lower the cylinder over the piston while compressing the piston rings with your fingers until the piston has fully entered the bore.

12. Make sure that the cylinder is properly seated in the crankcase. Install the cylinder head gasket; placing a thin coat of oil on both sides to ensure a good seal.

13. Refit the cylinder head, cylinder head washers and nuts and tighten the nuts in an "X" pattern in increments of about 5 ft lbs to the proper torque of 16 ft lbs for 250–500 models, 30 ft lbs for 750s.

14. The remainder of the assembly procedure is the reverse of disassembly.

CRANKCASE COVER COMPONENTS

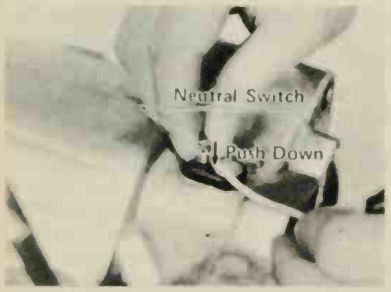
The alternator, or magneto countershaft sprocket, and clutch release mechanism are found beneath the left crankcase covers; while beneath the right crankcase cover are the oil pump, tachometer drive, primary drive gears, and the clutch.

To remove the alternator or magneto assembly, a special puller is necessary, while a holder of some sort will be necessary to remove the clutch, primary gear, and the countershaft sprocket.

In all cases, these parts can be serviced with the engine in the frame.

Alternator

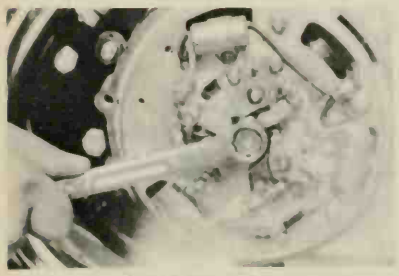
S-SERIES, KH250



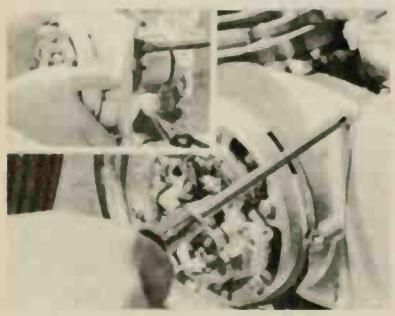
Removal

1. Remove the two phillips head mounting screws from the points cover and remove the cover.

Removing the points cover (S-series, KH250)



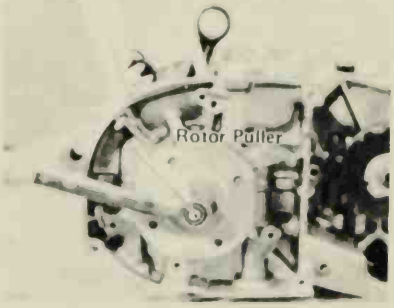
2. Remove the neutral switch wire from the neutral switch.



Disconnecting the neutral switch

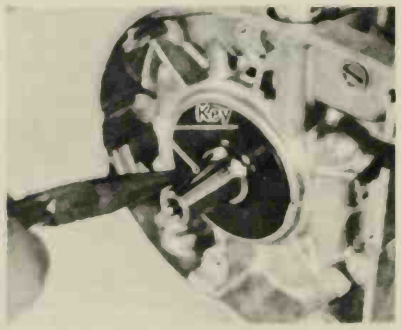
3. Disconnect the point and alternator wiring from the wire harness at the connectors.

4. Remove the breaker cam bolt.



Removing the breaker cam bolt

Removing the stator assembly



NOTE: *When removing the breaker cam bolt or using the rotor puller it will be necessary to keep the crankshaft from turning. Engage the transmission and apply the rear brake.*

5. Remove the four phillips head screws from the left crankcase cover and remove the cover, breaker plate, and stator as an assembly.

Removing the rotor

6. Remove the rotor with a rotor puller. Screw the puller into the center of the rotor to remove it from the tapered end of the crankshaft. Remove the woodruff key from the crankshaft.

Removing the woodruff key

Inspection

For inspection of the alternator components refer to the "Electrical System" section.

Installation

Assembly is the reverse of disassembly, however, note the following points.

1. Install the woodruff key in the slot in the end of the crankshaft.

2. Lubricate the tapered portion of the crankshaft with a thin coat of grease to make removal easier the next time.

3. Make sure that no metal objects have become attached to the rotor.

4. Draw the rotor down on the crankshaft with the mounting bolt. Do not attempt to drive the rotor onto the crankshaft by force as striking the rotor can affect its magnets.

5. Be sure that the rotor does not rub on the stator.

6. Check the ignition timing.

KH400

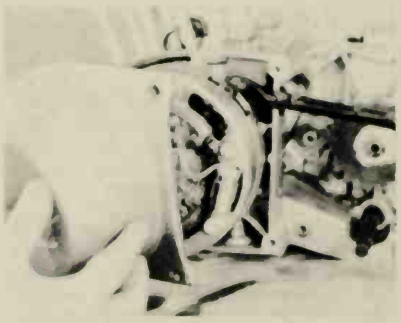
Removal

1. Remove the gearshift lever. Remove the front and rear sections of the left crankcase cover. Remove the front section's gasket.

2. Engage the transmission, apply the rear brake, and remove the magneto rotor bolt.

3. Using the special puller, remove the rotor.

4. Disconnect the magneto/alternator wiring. Remove the three stator plate screws and take off the stator plate.



Installation

1. Installation is the reversal of removal. When installing the stator plate, be sure that the timing marks on the plate and the crankcase are aligned.

H1-H1-D, H2

Removal

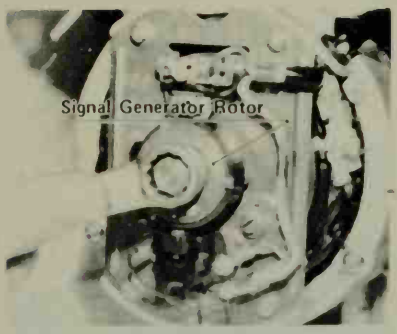
1. Remove the shift lever and the sprocket cover.

Removing the left engine cover (H1-A/D H2)

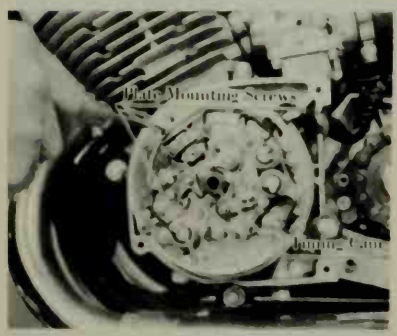
2. Remove the three mounting screws (on H1 models) or two mounting screws (H2) and remove the left engine cover.

3. Remove the neutral switch wire from the neutral switch.

4. Disconnect the ignition and alternator wiring from the wire harness at the connectors.



Disconnecting the wiring (H2)



5. CDI models: Remove the signal generator rotor bolt and pull off the signal generator rotor.

NOTE: *When removing the signal generator bolt or using a rotor puller, it will be necessary to hold the crankshaft from turning. Engage the transmission and apply the rear brake.*

6. H1 without CDI: Mark the breaker plate so that it can be installed in the same position as it is removed from. Remove the breaker cam bolt, the three

Removing the rotor

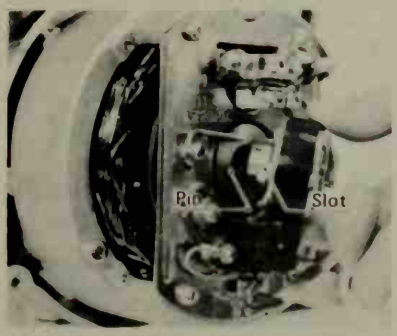
Removing the breaker plate (H1, breaker point ignition)

mounting screws, and remove the breaker plate.

7. H2 models: Remove the three stator mounting screws and remove the stator.

8. Remove the alternator rotor with a rotor puller. Screw the puller into the center of the rotor to remove it from the tapered end of the crankshaft. Remove the woodruff key from the crankshaft.

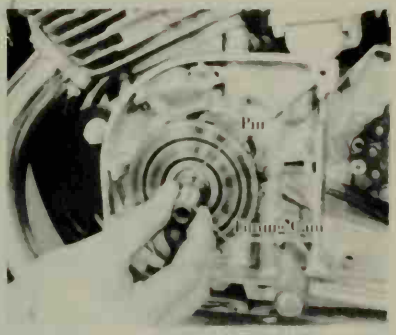
Inspection



For inspection of the alternator components, refer to the "Electrical System."

Installation

Assembly is the reverse of disassembly. However, note the following points:



1. After installing the alternator woodruff key, push the alternator rotor onto the shaft. Do not strike the rotor while installing it as this may affect its magnetic properties.

A bit of lubricant applied to the crankshaft taper will make future removal of the rotor easier.

Align the slot in the rotor with the pin on the alternator rotor (H1, battery-CDI)

2. Align the slot in the signal generator rotor with the pin on the alternator rotor. On the H1 with breaker point ignition, align the slot in the breaker cam with the pin on the rotor.

Line up the slot in the cam with the pin on the alternator rotor (H1, breaker point ignition)

H1-E/F, KH500

Removal

1. Proceed as for H1-H1D, H2 outlined above, Steps 1–4.

2. Remove the stator plate screws, and take off the plate complete with pick-up coils and carbon brushes. Remove the plate slowly as the brushes are spring-loaded.

3. Remove the screws which secure the stator windings.

4. Remove the signal generator rotor bolt, the signal generator rotor, and use the special puller to remove the alternator rotor.

Inspection

For inspection of the components, refer to "Electrical Systems."

Installation

Install components in the reverse of disassembly. Reset the ignition timing as outlined in "Tune-Up."

Countershaft Sprocket

REMOVAL

1. Remove the shift lever and the sprocket cover.

2. Remove the sprocket nut from the end of the countershaft after bending back the locktab.

NOTE: *When removing the sprocket nut it will be necessary to hold the countershaft from turning. If the engine is in the frame this can be done by placing the transmission in High gear and applying the rear brake while removing the nut. If the engine has been removed from the frame, wrap a piece of old drive chain around the sprocket and lock the other end in a vise.*

Bending down the locking tab on the countershaft sprocket nut

3. Loosen the rear axle nut and the sprocket nut and move the rear wheel forward in the swing arm until the chain can be lifted off the countershaft sprocket.

4. Slide the sprocket off of the countershaft.

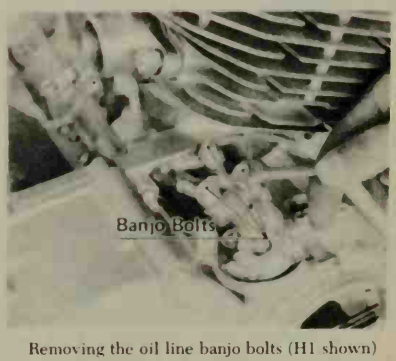
INSTALLATION

Installation is the reverse of the removal procedure. Ensure that the sprocket nut is firmly tightened and that the tab on the washer is bent up across one of the nut flats.

Right Crankcase Cover Components

RIGHT CRANKCASE COVER

Removal



NOTE: *On all models, the oil pump, tach and pump drive gears will remain in the cover when it is removed. They can be left undisturbed unless service is necessary.*

It will be necessary to bleed the pump before operating the machine, since the lines must be disconnected to remove the crankcase cover.

1. 250–400 only: Disconnect the tachometer cable from the oil pump cover. Remove the three mounting screws and remove the oil pump cover.

2. 500, 750 only: Remove the three mounting screws from the oil pump cover and slide the cover up the tachometer cable. Disconnect the tachometer cable and remove the oil pump cover.

3. Remove the three oil line banjo bolts and disconnect the oil lines from the pump and slip them out of the right crankcase cover. Be sure to keep track of the banjo bolt gaskets. Disconnect the oil pump cable from the control lever and remove it from the crankcase cover.

Removing the oil line banjo bolts (H1 shown)

4. H1 battery-CDI only: Unclip the distributor cap and remove it.

5. Remove the oil tank line from the oil pump by unscrewing the banjo fitting. Remove the banjo fitting from the oil line and plug the end of the line with a small screw.

6. Remove the kick-starter lever

pinch-bolt and pull the lever off the kick-starter shaft.

7. Drain the transmission oil. Place a drip pan beneath the crankcase cover.

Removing the right crankcase cover (H1, battery-CDI)

8. Remove the mounting screws and remove the crankcase cover; tap it carefully with a plastic mallet to break the seal if stuck.

9. Remove the cover gasket.

Installation

Installation is in the reverse order of disassembly, however note the following points:

1. A new cover gasket should always be used upon assembly.

2. H1 battery-CDI only: The ignition timing will have to be set when the cover is installed:

a. Use a dial gauge to set the right cylinder at TDC;

Line up the mark on the timing plate with the "T" mark on the engine case (H1, battery-CDI)

b. Turn the rotor until the mark on the rotor is pointing to the "T" mark on the crankcase cover;

c. Holding the rotor in this position mount the cover on the engine as described below. Be sure that the right cylinder is still at TDC.

3. Hold the cover in place and make sure that the oil pump gear and the distributor gear (H1 battery-CDI) are meshed with their drive gears. Install the mounting screws and tighten them in an "X" pattern a little at a time until they are all tight. Secure with an impact tool.

4. Refill the transmission with the correct amount of oil.

5. Bleed the oil pump and adjust the control cable.

OIL PUMP

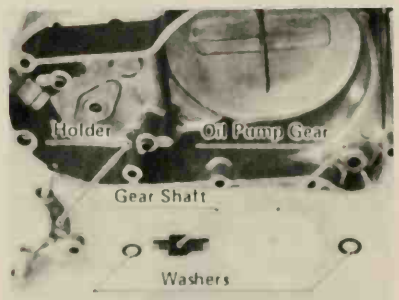
The pump is removed along with the right-side cover. For service to the oil pump refer to "Lubrication System."

TACHOMETER AND OIL PUMP DRIVES

1. Remove the right crankcase cover as previously described.

2. Pull the tachometer gear assembly out of the cover from the outside with pliers. On 500 and 750s, the nylon tach gear and thrust washer can be removed from the inside of the cover at this time.

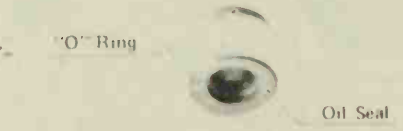
Removing the tach gear shaft (500, 750)



3. S-series: Remove the two phillips screws from the tachometer gear holder in the inside of the case. Remove the holder, gear shaft and nylon oil pump gear, noting the location of any thrust washers.

Removing the tach gear assembly (250–400)

4. Inspect the condition of all of the gears, replace any with badly worn, chipped, broken, or missing teeth.



5. Inspect the condition of the oil seal in the tachometer bushing. If the lips of the oil seal appear to be damaged, replace the seal with a new one.

Left crankcase cover tach and pump gears (250–400)

6. Check the O-ring for condition, if it is torn or cracked it should be replaced.

7. To install the tachometer gear assembly, replace the gear shaft, oil pump gear, and gear holder (250–400). Be sure that the slot in the gear shaft is fitted to the tab on the oil pump drive. On 500–750, hold the driveshaft gear and thrust washer in place.

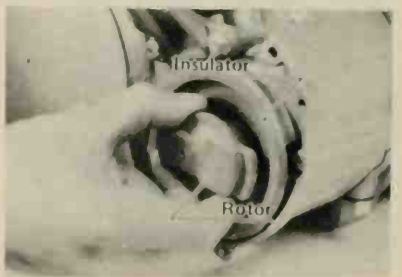
Check the tach oil seal and O-ring

Installing the tach gear assembly (250–400)

8. Slip the tachometer driveshaft through the bushing, and press the assembly into the case. Take care not to damage the O-ring or the oil seal. Check that the gears line up when pressing in the shaft. Note that a pin on the shaft must engage the slot in the tach gear (500–750).

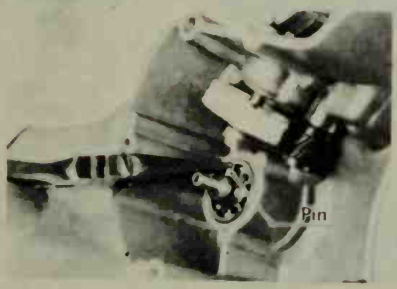
9. Install the right crankcase cover.

DISTRIBUTOR (H1 BATTERY-CDI)



1. Remove the right crankcase cover as previously described.

2. While holding the rotor remove the pinion gear nut from the end of the distributor shaft. Remove the pinion gear from the shaft.



Removing the distributor pinion gear nut (H1, battery-CDI)

3. Pull the rotor off the shaft, and remove the insulator from the crankcase cover.

Removing the rotor (H1, battery-CDI)

4. To remove the distributor shaft from the crankcase cover, remove the pin from the inside end of the shaft, then, using a soft-faced mallet, tap the shaft out from the inside.

Remove the pin to remove the distributor driveshaft (H1, battery-CDI)

5. Check the condition of the oil seal in the cover, if it is torn or cracked it should be replaced.

6. Replace the rotor if it is cracked or chipped.

7. Inspect the pinion gear and replace it if any of the teeth are chipped or missing.

8. Inspect the shaft for bends and replace if bent. Check the bearing condition. Rotation must be smooth and effortless.

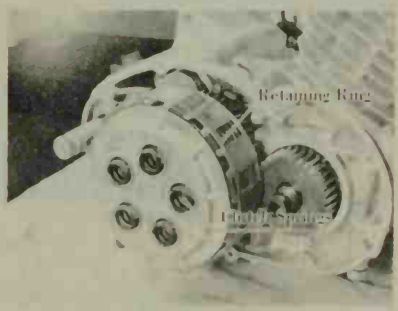
9. Inspect the condition of the threads on the end of the shaft. Replace the shaft if they are chipped or stripped.

10. Installation is the reverse of removal.

CLUTCH

Removal

1. Drain the transmission oil.



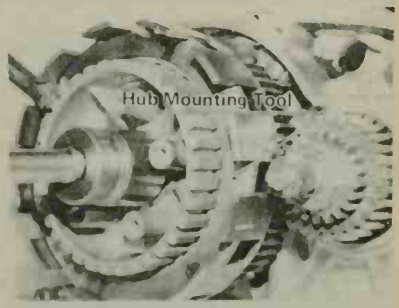
2. Remove the right crankcase cover as previously described.

NOTE: *If the primary drive (crankshaft) gear must be removed, it is advisable to loosen the primary drive gear nut with the clutch installed. Stuff a rag between the clutch and primary gears to lock them in place, then loosen the nut. Using impact (rather than steady pressure) on this nut will make removal easier.*

3. Loosen the five clutch spring plate bolts gradually and evenly, then remove them.

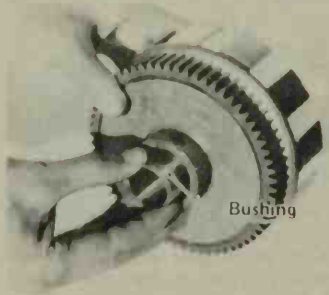
4. Remove the pressure plate with the clutch springs, and spring guides. On H2 models, remove the retaining ring from the clutch housing.

5. Remove the spring plate pusher from the center of the hub.



Clutch springs and retaining ring

6. Remove the clutch steel and friction plates. Note the steel bands fitted between each pair of friction and steel plates. Handle them carefully. Note the order of the plates and bands as they are removed. All components must be installed in the same order.



Removing the spring plate pusher

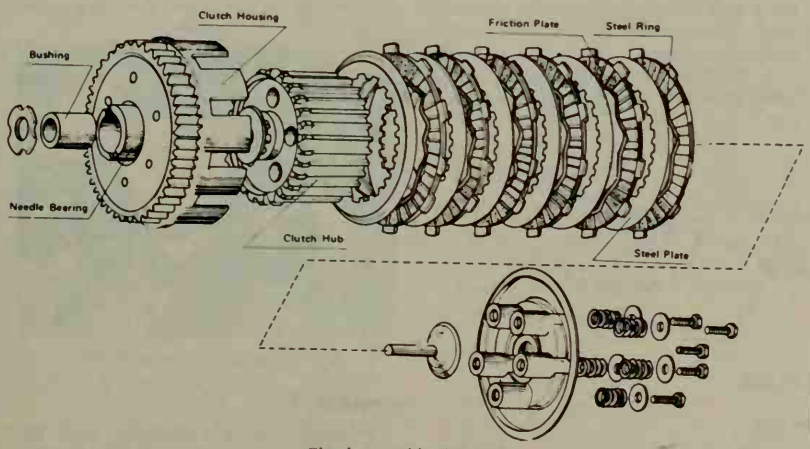
7. Remove the clutch hub nut. To remove the hub nut, either hold the hub stationary with the special tool, as shown, or engage the transmission and lock the countershaft sprocket in place.

Removing the clutch hub nut while the special tool keeps clutch from turning

8. Pull the clutch hub off the transmission mainshaft, and then remove the thrust washer behind the hub.

Checking the clutch housing bushing for play

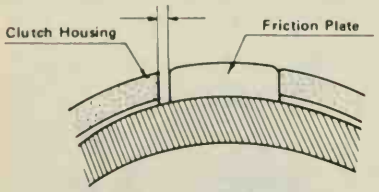
9. Remove the clutch housing. The housing needle bearing will remain in the housing in most cases. Remove the bushing and thrust washer from the mainshaft.



10. To remove the clutch release mechanism and the pushrods: remove the countershaft sprocket cover, disconnect the clutch cable from the clutch release assembly, and unscrew the two mounting bolts. Remove the release mechanism and the pushrods.

Removing the clutch release assembly

Removing the pushrod



Clutch assembly (250–400)

Inspection

1. Refer to the "Specifications" charts at the end of this section for individual models.

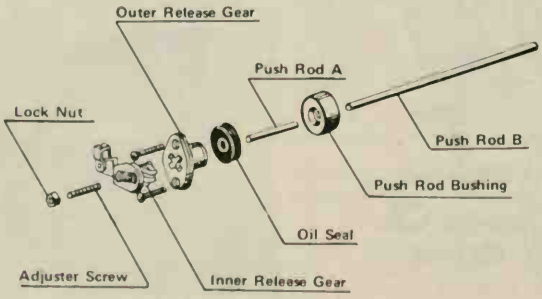
2. Check clutch spring free length, friction plate thickness, and steel plate warpage. If plate warpage exceeds 0.2 mm (0.008 in.), replace the plates as a set.

3. Check the clearance between the tabs on the friction plates and the slots in the clutch housing. If the clearance exceeds the service limit given in the "Specifications" chart, replace the housing. If replacing the housing does not bring the clearance into specification, the friction plates will also have to be replaced.

Check the clearance between the clutch housing and the friction plate tabs

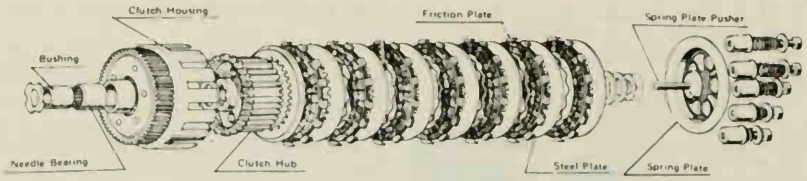
4. Check the condition of housing gear. The gear teeth should be free of wear. If any of the gear teeth are broken or extremely worn, replace the clutch housing and check the condition of the gear with which the worn gear meshes (the primary drive gear). Minor imperfections of the teeth may be remedied with an oilstone. Any gear which is worn enough to necessitate replacement should have its mating gear replaced as well, since it, too, is undoubtedly worn.

5. Place the bushing on the mainshaft and check for play. If play is noticeable, replace the bushing. Be sure that the bushing is free of score marks.

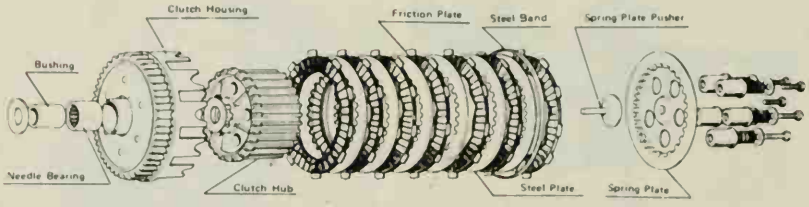


Check the bushing for excessive play in the clutch housing. If any is evident, check the condition of the housing needle bearing as well and replace both bushing and bearing if necessary.

6. Inspect the condition of the needle bearing; if the rollers are scored or discolored or the roller cage is damaged, the bearing should be replaced.



7. Check the general condition of the clutch release assembly pieces. The inner and outer release gears should mesh smoothly together. If they do not, check for damage and replace them.



The inner and outer release gears should mesh smoothly

Clutch release assembly (all models)

Clutch assembly (H1)

Clutch assembly (H2)

Installation

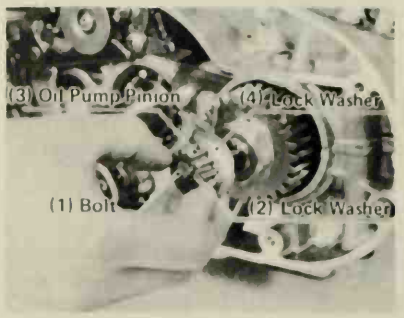
1. Clean all metal parts in a solvent. Lubricate them with transmission oil before assembly.

2. Install the clutch components in the reverse of the removal procedure, referring to the accompanying illustrations if necessary. Be sure that all thrust washers are correctly installed.

3. Be sure that the steel bands are in place between the friction and steel plates.

4. Tighten the clutch hub nut securely.

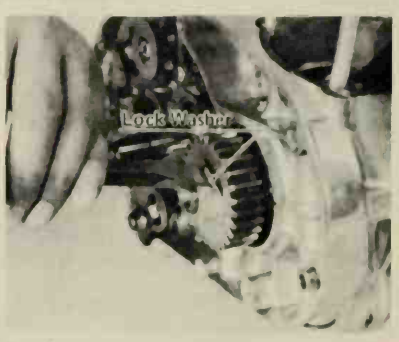
5. Spring plate bolts should be tightened gradually and evenly.



PRIMARY GEAR

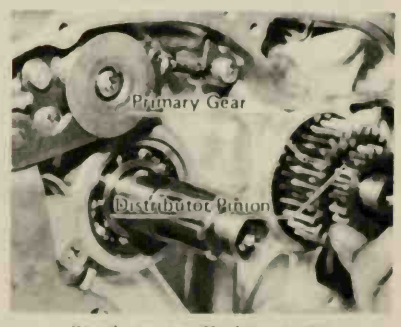
Removal

1. As noted, the primary drive gear nut should be loosened with the clutch installed.



2. Stuff a rolled up rag between the primary and the clutch housing gears to lock them in place, then remove the oil pump drive gear bolt from the end of the crankshaft. Remove the oil pump drive gear and lockwasher.

3. Bend down the locktab on the primary gear nut washer and unscrew the nut.



Removing the pump drive gear assembly

4. Remove the distributor drive gear (H1 battery-CDI), lockwasher, and the primary drive gear. Remove the key from the crankshaft.

Bending back the primary gear nut washer locktab

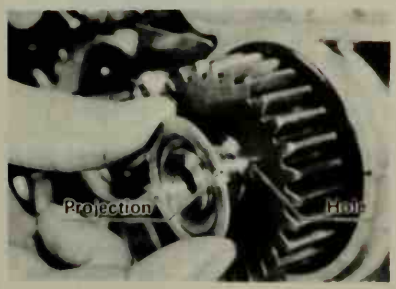
Distributor gear (H1, battery-CDI)

Inspection

1. Check the gear teeth for wear. Replace if necessary. If the primary gear is

excessively worn, the clutch gear should be replaced as well. Minor defects of the teeth can be remedied with an oilstone.

2. Check the woodruff key for stepwear and replace it if it shows signs of wear or if it is a loose fit in the crankshaft keyway or the gear.



3. Inspect the oil pump drive gear for worn teeth and replace it if necessary. Inspect the pump driven gear in the case cover as well.

Installation

1. Installation is the reverse of the removal procedure.

2. The crankshaft should be smeared with some oil before installing the gears.

3. Do not forget to install the woodruff key.

The primary gear nut washer projection must be fitted into the hole in the primary gear

4. When installing the primary gear nut lockwasher be sure that the projection on the washer is fitted into the hole in the primary gear. Tighten the primary gear nut securely, and bend up the side of the washer against the flat on the nut.

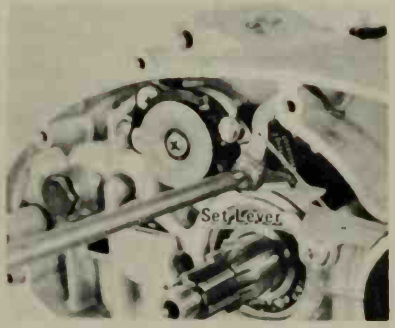
SHIFTER MECHANISM

Removal

On all models the shift arm and shaft can be removed and inspected with the engine in the frame.

1. Remove the right crankcase cover and clutch assembly.

2. Remove the gearshift pedal and the countershaft sprocket cover.



3. Disengage the shifter arm from the

Disengaging the fingers from the shift drum and pulling out the shifter shaft

shift drum and pull the shift lever out from the right-side.

4. Remove the mounting screws, and remove the set lever and its spring and the positioning plate.

Removing the set lever

Inspection

1. Check the splines on the gearshift shaft for wear or splintering, and replace the shaft if they are too badly damaged to properly secure the gearshift pedal.

2. Check the shaft for a bent condition and replace it if bent.

3. Check the shift arm for straightness. Check the shift fingers for straightness, and especially for wear at the tips.

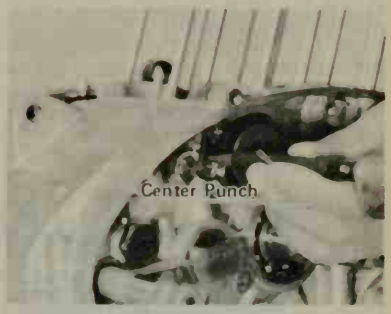
4. Inspect the shifter return spring and replace it if broken, or if the ends of the spring show signs of twisting or fatigue.

Removing the shift drum positioning plate

Check the shifter return spring for damage

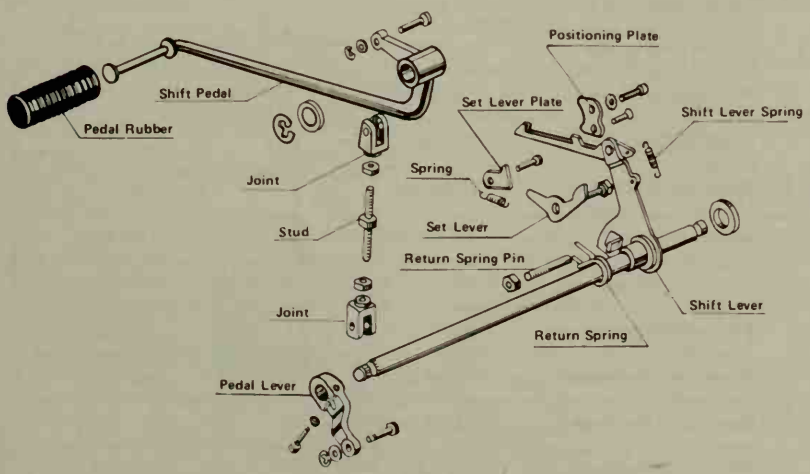
5. Check the other springs in the shift linkage and replace any that are deformed, damaged, or weakened.

6. Inspect the set lever and replace it if worn.



Installation

1. Installation is the reverse of the removal procedures.



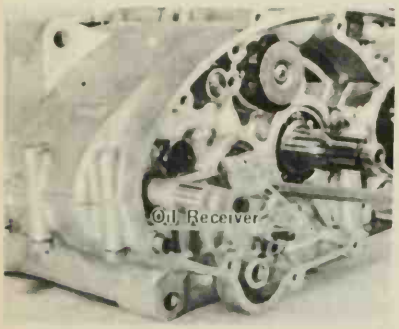
2. When installing the return spring, be sure that both ends of the spring bear tightly against the pin. The spring ends should be parallel to one another. This will provide the tension needed to keep the (foot) shift lever in position after each shift.

3. Be sure that the spring is secure in the crankcase.

4. When installing the positioning plate, stake the head of the mounting screws with a punch.

Staking the shift drum positioning plate screw

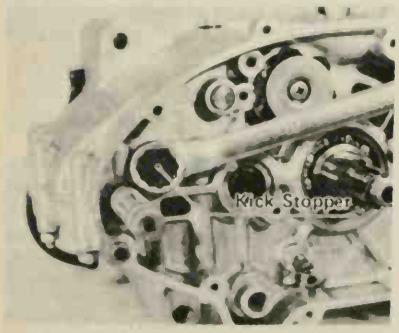
Gearshift assembly



LOWER END AND TRANSMISSION

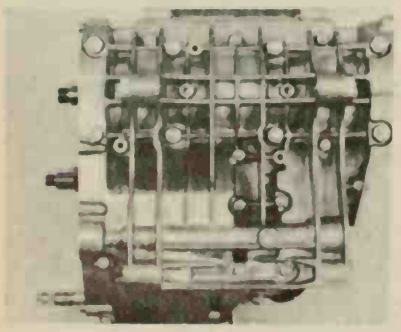
The following section deals with service to the crankshaft, transmission, kick-

starter mechanism, shifter (drum) assembly, crankcase bearings, and seals. Removing the engine and splitting the crankcases is necessary to service these components.



Splitting the Crankcases

1. Remove the engine from the frame. Remove the top end assembly. Remove the side cover components: alternator, countershaft sprocket, clutch, primary drive gear, shifter mechanism, clutch release mechanism.
2. Remove the oil receiver on the right-side of the engine.



Removing the oil receiver plate

3. Remove the kick stopper bolt.

Loosen the kick stopper bolt

4. Turn the engine upside down and remove the mounting nuts. Turn each nut ¼ turn at a time until they are all loose and then remove them.
5. Tap all around the crankcase mating surface with a soft-face or a plastic mallet. When the lower case comes free, remove it. The crankshaft and gear clusters will remain in the upper crankcase half.

Lower crankcase nuts

Kick-starter components

Crankshaft

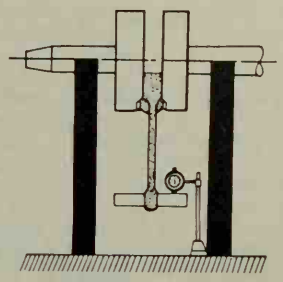
The crankshaft is a pressed together unit. Therefore, in the event of damaged crank, crank bearings, or connecting rods the crankshaft should be replaced as a unit.

1. Lubricate the big end bearings with two-stroke oil. Rotate the rod slowly around the crankpin. The movement should be smooth and noiseless.

2. With the crankshaft mounted in a jig, and a dial indicator mounted to bear against the small end of the connecting rod, check the vertical movement of the rod. It should not exceed the service limit given for big end bearing radial play in the "Specifications" chart at the end of this section. If the movement exceeds this figure, the con rod big end bearing is worn, and the crankshaft should be replaced.

Check for big end bearing radial play

3. Check the connecting rod side clearance with a feeler gauge placed between the rod big end and one of the flywheels. Side clearance should be 0.4–0.5 mm (0.0157–0.0197 in.), if the side clearance is more than 0.7 mm (0.0276 in.), the crankshaft should be replaced.



Checking connecting rod big end bearing-to-flywheel clearance

4. Mount the crankshaft in a set of V-blocks, and mount a dial guage to the main bearings. Rotate the crankshaft slowly and note the indicator readings. The maximum allowable run-out is 0.10 mm (0.0039 in.). If run-out exceeds this figure, replace the crankshaft.

5. With the crankshaft mounted in a jig, as shown, insert a shaft of the same diameter as the wrist pin into the small end bearing. Measure the distance between the base of the jig and the shaft on both sides of the rod, any difference in the two measurements indicates the con rod is bent. Also check that the shaft is parallel to the crankshaft; if not the con rod is twisted.

6. Clean and lubricate the main bearings. Check that each bearing rotates smoothly. If, in any bearing, play can be felt or rotation is other than smooth, the bearing is beyond its service life.

7. The crankshaft oil seals must be in good condition to maintain fuel transfer compression in the individual crankcase compartments. If the seal lips are damaged or worn, or if there is evidence of leaking (discoloration), the seals should be replaced. Scratches on the surface of the outer seals, caused by pinching when the crankcases are assembled, are not harmful.

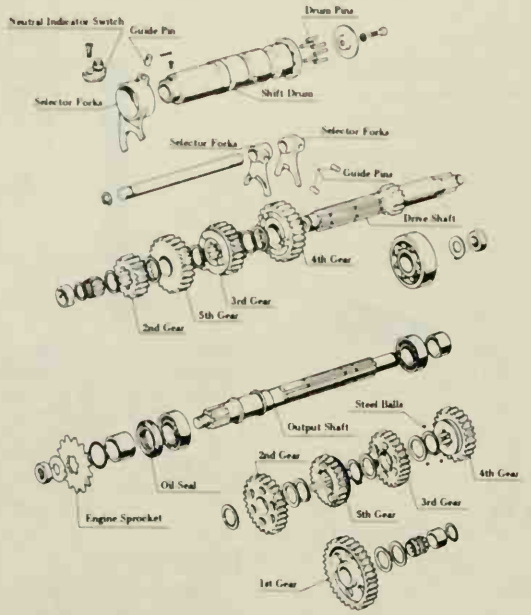
Checking for a bent connecting rod

Transmission

1. The gears should not be removed from their shafts unless absolutely necessary. If the gears are being removed, be sure that each gear, thrust washer, shim, and snap-ring is laid out in the order of removal so that it can be installed in the proper location.

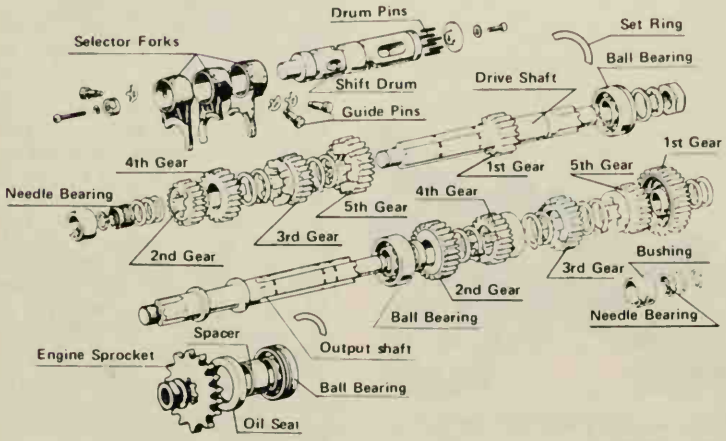
CAUTION: *Note the three steel balls inside the countershaft Fourth gear (S-series). If the transmission shafts are disassembled, refer to the exploded views of the transmissions as a guide to assembly. Note, however, that the number and location of the thrust washers fitted to individual transmissions may vary from the illustrations. These are used to adjust gear clearances (see below), and may differ from machine to machine.*

2. Check each of the gears for chipped, broken, or worn teeth. If any gear shows evidence of such damage, it should be replaced. In addition, the gear with which it meshes should be replaced as well, since it has undoubtedly been overstressed. Minor imperfections can be removed with an oilstone.



3. Check the inner splines on those gears so equipped, and replace the gear if the splines are worn or broken. Inspect the corresponding splines on the shafts. The shafts should be replaced if damaged.

4. Inspect the engaging dogs on gears which have them. The dogs must not be worn, chipped, or broken. Replace the gear if they are.



5. Inspect the transmission shafts for damage to the sprocket nut threads, and wear or damage to the clutch, gear, or sprocket splines. Make sure that the shafts are not bent.

6. Where applicable, check the transmission gears for smooth rotation on their shafts. If rotation is rough or noisy, replace the gear. Check that the inner surfaces of gears with plain bores are smooth.

7. Check the shaft bearings for condition. Replace any bearing if movement is balky or noisy, or if there is damage or

S-series transmission

H-series transmission

discoloration to the bearings or races.

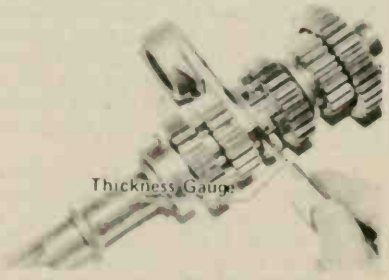
8. With the gear clusters assembled in the cases, check the gear side clearances with a feeler gauge as follows:

a. Clearance between the mainshaft Second gear and the bearing;

b. Clearance between the countershaft First gear and the bearing;

c. Clearance between the countershaft Second gear and Fourth gear (500, 750) or Fifth gear (250–400) snapring.

In each case, clearance should be 0.020 in. (0.5 mm) or less. To bring the clearance to within the proper specification, add a transmission shaft thrust washer where shown in the exploded views of the transmissions.



CAUTION: *If the addition of the washer makes the shaft difficult to turn, delete it.*

Shift Drum

1. The shift drum itself should be inspected for wear in the selector fork guide pin grooves, damaged guide pin lockwashers, and scoring or wear of the bearing surfaces.

2. The selector fork shaft (250–400) should be inspected for wear in those areas on which the selector forks ride. Roll the shaft along a flat surface to check it for a bent condition. Replace the shaft if bent.

3. Check the selector forks themselves. Note any wear to the fork bore. Check the fingers for bends, or for chipping or wear. Replace any fork on which such defects are noted.

Checking selector fork-to-gear clearance

4. Check the guide pins for wear, and replace them if damaged.

5. Check the shift drum pins. Replace any broken, worn or missing pins.

6. With a feeler gauge measure the clearance between the selector fork fingers and the groove in the gears. The standard clearance is 0.05–0.25 mm (0.002–0.01 in.); if the clearance exceeds 0.6 mm (0.024 in.), the gear and/or the selector fork should be replaced.

Kick-Starter

1. Rotate the gear on its shaft splines; operation should be smooth. Check for damage to the gear teeth (inner and outer) and to the shaft.

2. Check the condition of the splines on the end of the kick-starter shaft and replace the shaft if the splines cannot maintain a good grip on the kick lever.

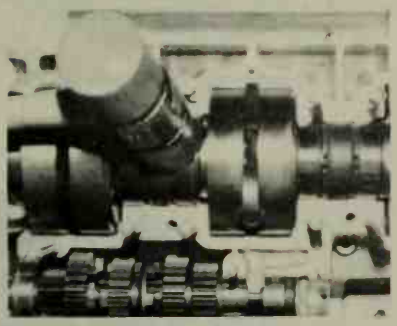
Checking the movement of the kick-starter gear on its shaft

3. Inspect the return spring and replace it if the ends are broken or deformed.

4. The gear holder should be a snug fit on the gear.

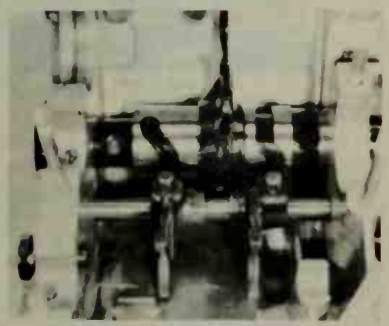
Assembly of Crankcases

1. Check that the oil passages and the transmission breather hole are clear. Blow them out with compressed air if possible.



Be sure that the bearing set rings are properly installed

2. Clean the crankcase mating surfaces thoroughly.



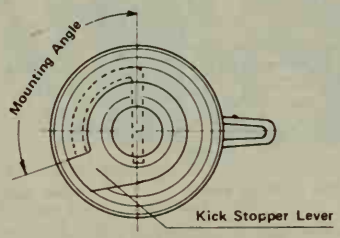
3. Make sure that the crankshaft main bearings set rings are properly installed in the upper crankcase and install the crankshaft. Seat the main bearings by tapping them lightly with a plastic mallet.

4. Fit the transmission shafts into the upper crankcase. Position the selector forks so that the center fork faces the front

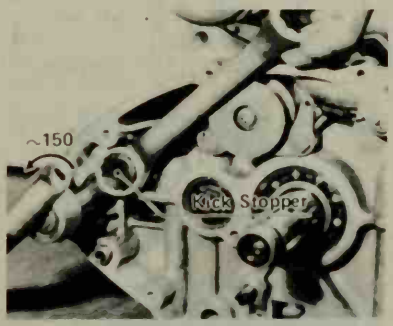
of the engine and the outer fork faces the rear. Fit the countershaft first and then the mainshaft. Be sure that the selector forks are correctly fitted to the grooves in the proper gears. The center fork is fitted to the mainshaft 3rd gear and the left and right forks are fitted to the countershaft 5th and 4th gears, respectively.

Seating crankshaft bearings

Position the selector forks as shown before installing the gears (250–400 shown)



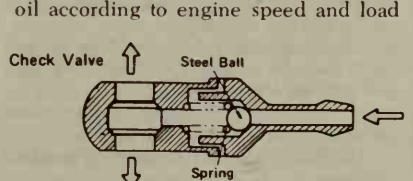
5. Assemble the kick-starter. Be sure that the circlips and snap-ring are properly seated in the shaft. Install the kick-starter assembly in the case, noting that the end of the gear holder should be fitted into the boss in the crankcases. After the cases are assembled the return spring must be preloaded and the kick stopper installed.



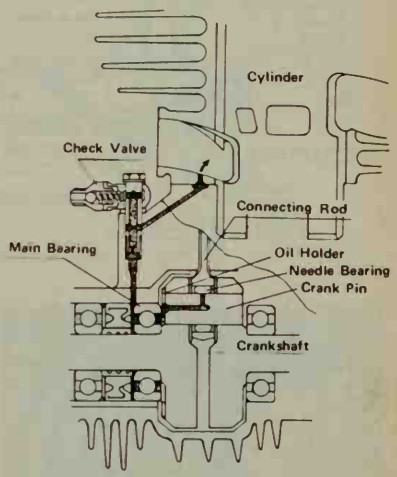
The kick-starter gear holder should be seated in the crankcase boss

6. Apply a thin coat of gasket sealer to the crankcase surfaces. Install the lower crankcase. Tighten the crankcase nuts in an X pattern in 3 ft lb increments starting from the center of the case. Torque the 8 mm nuts to 18 ft lbs and the 6 mm nuts to 11 ft lbs.

7. Install the kick-starter lever on the shaft and rotate it counterclockwise about 150° and holding the lever in this position install and tighten the kick stopper bolt. Release the lever and check that the spring has sufficient preload to return the lever to the stop.

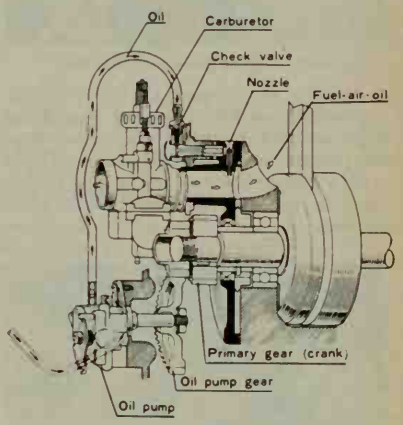


Rotate the kick-starter shaft about 150°, then install the stopper bolt to preload the spring



8. The remainder of the assembly procedure is in the reverse order of disassembly. Refer to the appropriate sections preceeding for assembly details on the remaining engine components. Pre-lube the crankcase oil passages with two-stroke oil.

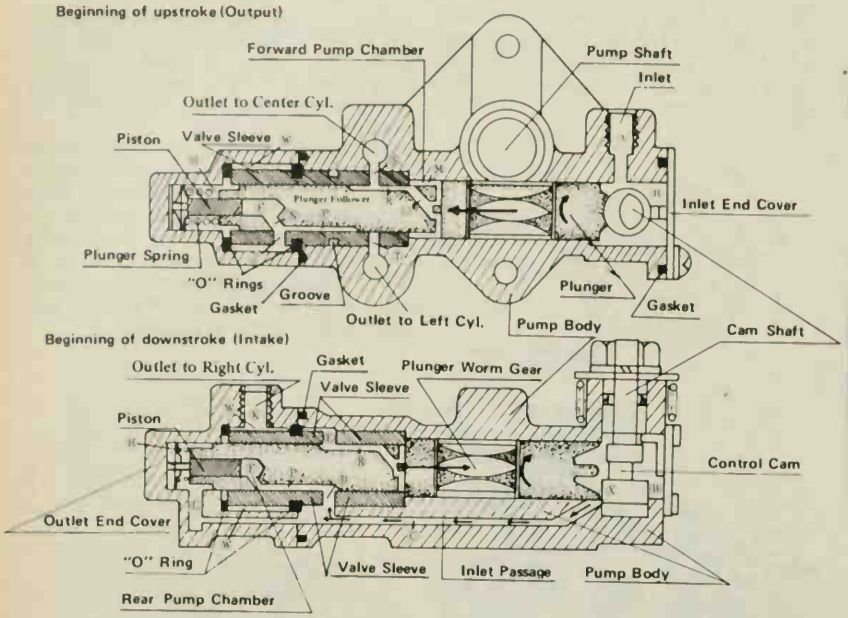
LUBRICATION SYSTEM



Both Superlube and Injectolube systems include an oil reservoir, oil feed line, oil pump, and oil delivery lines. The pumps are of the plunger type and are driven by the end of the crankshaft through reduction gears. The amount of oil fed to the induction passage delivery line and crankcase drillway (Injectolube) is determined by two variables: the speed of plunger operation and the length of plunger stroke. These variables are set by the engine rpm and the degree of throttle opening, respectively. The pump effectively meters the amount of oil according to engine speed and load and, as a result, no more and no less than the required amount is consumed. The pump also houses a check valve that keeps the oil output pressure constant and seals the delivery line when the engine is not operating.

The essential difference between the Superlube and Injectolube systems is the extra lubrication to the crankshaft main bearings and large end connecting rod bearings provided by the Injectolube type. An additional output port in the oil pump leads to a drillway in the crankcase, which in turn leads to smaller passages to these critical points.

Injectolube: the crankshaft bearings are lubricated directly by the pump



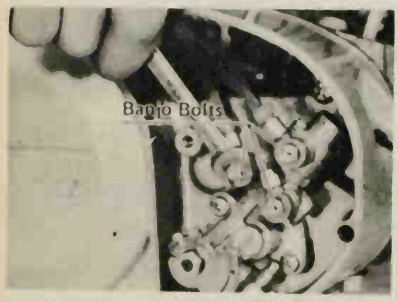
Superlube

OIL PUMP

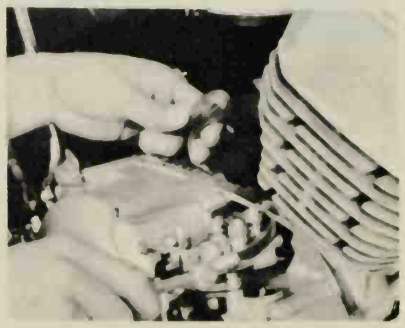
Removal and Installation

1. 250–400 only: Disconnect the tachometer cable from the oil pump cover. Remove the three mounting screws and remove the cover.

2. 500 and 750 only: Remove the three mounting screws from the oil pump cover and slide the cover up on the tachometer cable. Disconnect the tachometer cable and remove the oil pump cover.



Oil pump operation (500, 750)



Oil pump mounting screws (250–400 and 750)

Oil pump mounting screws (500)

Disconnecting the banjo bolts (250–400)

Disconnecting the oil tank line (H1 shown)

3. Remove the three oil line banjo bolts and disconnect the oil lines from the pump. Cover the ends of the oil lines with a plastic bag secured with a rubber band to prevent dirt from entering the system.

Disconnecting the banjo bolts (500)

Plugging the delivery line

4. Disconnect the oil pump cable from the pump control lever.

5. Remove the oil tank line from the oil pump by unscrewing the banjo fitting. Remove the banjo fitting from the oil line and plug the end of the line with a small screw.

6. Remove the two phillips head mounting screws and pull the pump off the right crankcase cover.

7. To install, mount the pump to the right crankcase cover with the two mounting screws. Be sure that the tab on the oil pump drive is fitted into the slot in the oil pump driveshaft.

8. Install the oil lines. Make certain that they are securely fastened, and that all gaskets are in place.

9. Connect the pump control cable and adjust it as described below.

10. Bleed the oil lines as described below.

Pump Repair

The factory advises against attempting to disassemble and repair the oil pump. The internal parts are machined to very exacting tolerances and it is highly unlikely that the pump can be reassembled to factory specifications. In addition to this, oil pump failure is *very* seldom due to internal malfunction.

The condition of pump o-rings is critical. Replace the o-rings if in doubtful condition.

Pump Output

H2-B/C

1. Drain the gas tank and refill it with a gas/two-stroke oil mixture in a ratio of 20:1.

2. Remove the oil pump cover. Detach the banjo bolt and oil line from the right-side carburetor and fit a 6 mm screw to the carburetor.

3. Loosen the banjo bolt at the oil pump and take out the check valve. Tighten the banjo bolt.

4. Check that the oil tank has plenty of oil. Run the free end of the disconnected oil line into a measuring cup or something similar.

5. Start the engine. While running it at 2,000 rpm, hold the oil pump open for three minutes.

6. Measure the amount of oil collected. Proper output is 0.17–0.20 oz. (4.9–5.9 cc).

7. If output is not within this amount, check oil pump o-ring condition. Replace them if damaged. If the problem is not rectified, replace the pump.

8. Flush out the gas tank; bleed the oil pump.

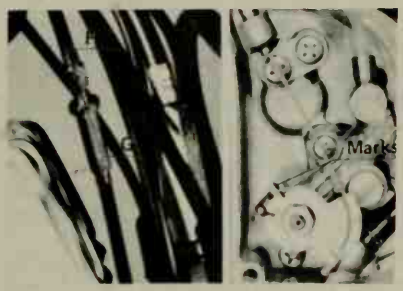
OTHER MODELS

1. Drain the gas tank and refill it with a gas/two-stroke oil ratio of 20:1.

2. Remove the oil pump cover. Disconnect the oil line for the right cylinder at the crankcase or carburetor.
3. Check that the oil tank has plenty of oil.
4. With the disconnected line emptying into a measuring cup or the like, start the engine and run it at 2,000 rpm for three minutes while holding the oil pump lever fully open.
5. Oil pump output should be as follows:
500: 0.17–0.20 oz. (5.1–5.8 cc)
H2: 0.23–0.26 ox. (6.8–7.5 cc)
250: 0.11–0.13 oz. (3.2–3.9 cc)
350, 400: 0.13–0.15 oz. (3.8–4.4 cc)
"S1," "S2-2" (pump marks): 0.11–0.13 oz. (3.8–4.4 cc)
6. If output is unsatisfactory, check oil pump o-rings and replace if in bad or doubtful condition. If this does not rectify the problem, replace the pump.
7. Flush the gas tank and bleed the pump.
after the throttle cables.

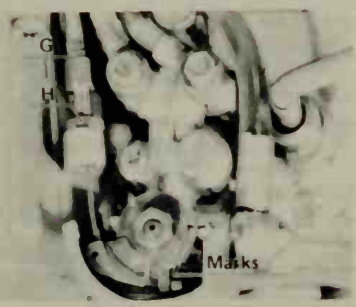
PUMP BLEEDING

The oil pump must be bled of air between the pump and check valve, and between the reservoir and pump whenever the pump is removed, the delivery lines are disconnected, or the reservoir has run dry.
1. Remove the oil pump access cover.
2. Start and run the engine at 2,000 rpm while holding the pump control lever in the fully open position.



Hold the lever fully open while bleeding the pump (H1 shown)

3. Observe the output delivery line. Any air bubbles in the system should disappear quickly. If they do not, check the tightness of the input and output line banjo bolts.
4. If there are air bubbles in the reservoir oil delivery line, disconnect it at the pump and allow oil to flow through it until the bubbles are gone, then reconnect it and repeat Steps 2 and 3. The reservoir delivery line must not be disconnected while the engine is running.

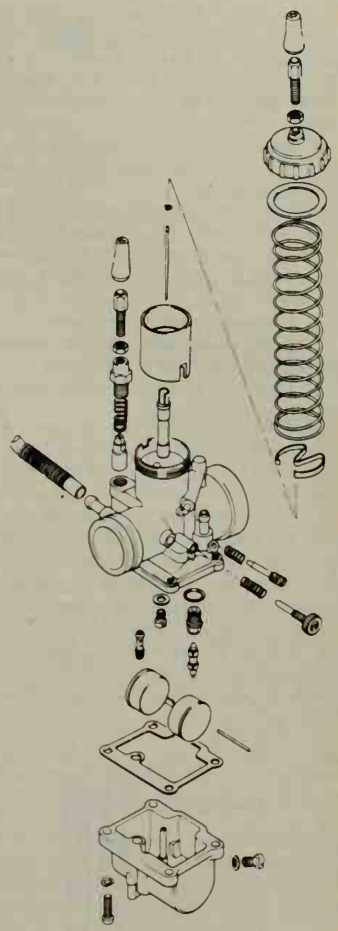


OIL PUMP CABLE ADJUSTMENT

1. The oil pump should be adjusted after the throttle cables. Refer to "Tune-Up."

Oil pump cable adjustment (250–400 and 750)

2. The oil pump lever must start to move at the same time the throttle slides start to open.
3. Use the cable adjuster so that the marks on the oil pump control lever and the lever stopper are aligned at zero throttle opening.



Oil pump cable adjustment (500)

FUEL SYSTEM

NOTE: *For carburetor theory, component inspection, and troubleshooting, refer to "Carburetors" in the "General Information" section.*

Removal and Installation

Before disassembling the carburetors, have overhaul kits on hand. All gaskets and O-rings should be replaced.
1. Carburetors are removed one at a time. Before removing each carburetor from the manifold, loosen the carburetor cap ring nut and the starter cable fitting on the carburetor body.
2. Turn the petcock "off" if it is the standard type, and disconnect the fuel line at the carburetor.
3. Loosen the air cleaner hose clamp screw on either outside carburetor, and remove the air cleaner hose.
4. Loosen the carburetor clamp screw at the manifold and pull off the carburetor. Disconnect any breather or overflow lines.
5. Lift up the rubber cap cover, unscrew the cap ring nut, and pull out the throttle slide assembly. Unscrew the starter plunger unit. Drain the fuel from the float bowl.
6. Repeat the procedure for the two remaining carburetors.
7. Installation is the reverse of the above. Be certain that the carburetors are vertical on their manifolds. Secure the manifold and air cleaner hose screws. On machines with "diaphragm" petcocks, turn the petcock to the "prime" position to fill the float bowls with fuel.

Mikuni carburetor SC-series

Disassembly

If disassembly of the throttle slide assembly is desired, refer to the procedures below. If a throttle-stop rod is used to adjust the idle speed, as on some models, see Step 1 and following. On models with a body-mounted screw for idle adjustment, begin with Step 2.

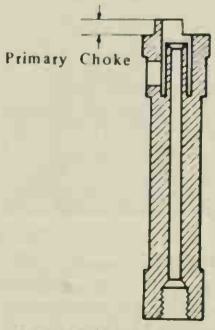
1. The idle speed adjusting screw on the carburetor cap has a small cotter pin at the top. Removing this pin will allow the throttle stop rod to be removed from the bottom of the slide.
2. Compress the throttle slide against the cap until the end of the cable protrudes from the bottom of the slide. Slip the cable end free of the slide, then remove the spring and slide.
3. Remove the spring seat from the inside of the slide, then turn it upside down to remove the needle and clip.
NOTE: *Do not remove the clip from the needle unless making a tuning change.*
4. Turn the carburetor upside down, and remove the four float bowl screws. Remove the float bowl.
NOTE: *If the carburetor is old and has*

never been disassembled, the float bowl may be stuck to the gasket. Use a soft-faced (plastic) mallet to tap around the bowl until it is free. Restraint should be exercised while doing this.

5. Push out the float pivot pin by hand or with a small punch, and remove the float assembly.

CAUTION: *Carefully note or mark the top side of the float assembly, since damage could occur if the attempt were made to install the float incorrectly.*

6. Remove the float needle.



7. With a suitable socket, unscrew and remove the float needle seat.

8. Unscrew and remove the main jet.

CAUTION: *All fuel jets are very malleable and must be removed and installed with care to avoid damage.*

9. Unscrew and remove the pilot jet.

10. The needle jet is located above the main jet and is a press-fit in the carburetor body. Removal is not usually necessary unless the jet is to be replaced. To remove the needle jet, remove the washer press-fitted into the carburetor just beneath the needle jet. Use a small wooden dowel to tap the bottom of the needle jet and force it into the carburetor bore.

Install the primary choke of the needle jet facing the air cleaner side of the carburetor, the cutout faces the engine side

CAUTION: *When installing the needle jet note that it must be installed with the cutout at the top of the jet facing the ENGINE side of the carburetor.*

Assembly

1. All gaskets should be replaced when overhauling a carburetor.

2. On models with a rod-operated throttle slide, assemble by first fitting the carburetor cap onto the throttle cable. Install the stop rod through the bottom of the slide and secure it with the cotter pin to the top of the idle adjusting screw on the carburetor cap.

3. Install the needle, making sure that the needle clip is properly positioned, and that the clip position is the same for all three carburetors.

4. Install the spring seat, return spring, and engage the throttle cable on the slide in the reverse of the disassembly procedure.

5. Install the pilot jet, being careful when screwing the jet in that it is properly seated.

6. Install the needle jet, as on removal, with a wooden dowel drift, tapping it into its seat from the carburetor bore. Install the washer.

Be sure that the jet is installed with the cutout at the top facing the engine side of the carburetor.

7. Install the main jet.

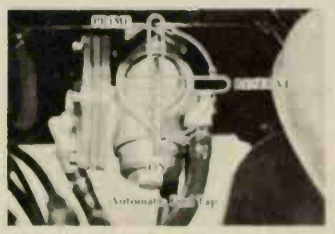
8. Install the fiber gasket onto the float needle seat and screw the needle seat into the carburetor.

9. Insert the float needle into the seat, and position the float assembly over the needle, ensuring that the correct side faces up. Slip the float pivot pin into the holder.

10. Check the float level as outlined in "Tune-Up."

11. Fit a new float bowl gasket. Refit the float bowl, insert the four phillips head screws and tighten them gradually, and in an "X" pattern.

12. Refit the pilot air screw. Screw it in gently until seated, then back it out the prescribed number of turns given in the "Carburetor Specifications" chart at the end of this section. This is an approximate setting and may have to be readjusted after the engine is started.



13. Install the throttle stop screw (if fitted) to the carburetor body.

14. Install the carburetor on the manifold, slip in the throttle slide and needle and secure the cap ring nut. Fit the plunger assembly to the carburetor body. Secure the manifold clamp screw.

15. Refer to the "Maintenance" and "Tune-Up" sections if necessary to adjust the pilot air and throttle adjustment stop screws, cables, and slide synchronization.

FUEL PETCOCK

Two types of petcocks are in use: the standard three-position type, and a diaphragm type. The diaphragm petcock is left in the "on" position at all times except when switching to "reserve." Use the "prime" position to fill the carburetor float bowls if they have been emptied. No fuel should flow out of the petcock in the "on" and "reserve" positions unless the engine is running.

Diaphragm-type petcock (pre-1975)

1. The petcocks contain a wire mesh filter which should be removed and cleaned every few months, or at 2,000 mile intervals.

2. If a sediment bowl is fitted, turn the petcock lever so that fuel will not flow, and unscrew and remove the sediment bowl, O-ring, and filter screen. On petcocks without sediment bowls, the filter screens are fitted to the petcock intake pipes inside the tank. Remove and drain the gas tank, unscrew the petcock nut, and remove the petcock from the tank.

Petcock body (1), and filter screen (2)

3. Clean all metal parts in solvent. Be sure that the filter screens are clean.

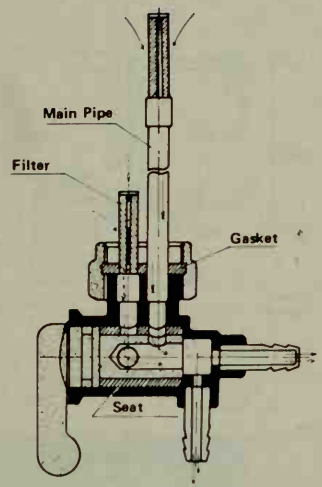
4. Make sure that the petcock fully shuts off the gas (standard type), or does not leak gas in the "on" position (diaphragm type). If leakage is noted, the petcock should be replaced.

5. Check the condition of the sediment bowl O-ring, or petcock gasket, and replace it if damaged.

6. Replace the filter and sediment bowl. Do not overtighten the bowl. After installation, check for leaks.

7. If water has accumulated in the gas tank, some or most of it can be removed if the standard-type petcock is fitted by disconnecting the fuel lines at the petcock, placing a suitable container beneath it to catch the gasoline, and turning the petcock lever to the "Reserve" position. Letting the fuel flow for several seconds in this manner should remove any water present around the petcock pipe in the gas tank.

8. After extended periods of time, removal and thorough cleaning of the petcock is recommended. Remove the gas tank and drain off all the fuel. Unscrew and remove the petcock body from the gas tank. Unscrew and remove the sediment bowl and filter.



9. On diaphragm-type petcocks, remove the diaphragm plate securing screws, and remove the plate and diaphragm.

Removing the petcock (diaphragm-type)

10. Clean the fuel pipe filters and the petcock body thoroughly in gasoline. Be sure that all passages are clear.

11. Assembly is the reverse of disassembly. On diaphragm-type petcocks,

Standard-type petcock showing fuel filter screens

align the air vents in the petcock body, diaphragm, and plate as illustrated.

12. Check the condition of the sediment bowl O-ring and replace it if damaged. Check the mounting nut gasket and replace it if cracked or crushed.

On diaphragm-type petcocks, be sure that the air vents are aligned when assembling

Carburetor Specifications①

Model	Carburetor	Main Jet	Needle Jet	Needle	Pilot Jet	Slide Cut-away	Air Screw (turns out)
S1, KH250	VM22SC	75	O—0	4EJ8—3 or 4EJ7—3	20.0	2.0	1½
S2	VM24SC	85	O—2	4EJ4—3	25.0	2.0	1½
S3	VM26SC	85	O—2	4EJ9—3	17.5	2.5	1¼
KH400	VM26SC	77.5	O—6/4	4EJ4—3	20	2.5	1¼
Early H1 (with CDI)	VM28SC	100	O—2	5GL3—3	30.0	3.0	1¼
Early H1 (without CDI)	VM28SC	90	O—2	5EH7—3	30.0	2.5	1½
H1-B	VM28SC	95	O—4/8	5DJ19—4	30.0	2.0	1½
H1-C	VM28SC	100	O—2	5GL3—3	30	3.0	1¼
H1-D, H1-E/F	VM28SC	92.5	O—4/8	5DJ19—4	30	2.5	1¼

H2, H2-A	VM30SC	97.5	O—6/8	5EJ15—3	35	2.5	1½
H2-B/C	VM30SC	102.5	O—6/8	5EJ15—4	40	2.5	1¾

① Specifications may differ according to model year, manufacturing lot, etc.

13. After assembly, check for leaks.

14. On diaphragm petcocks, be sure that the vacuum line is airtight, or fuel flow will be cut off. The vacuum line should be completely free of cracks and should be firmly attached at both ends. Replace the line if damaged, or if the ends have stretched, resulting in loose fitting at the connection points.

ELECTRICAL SYSTEM

IGNITION SYSTEM

Breaker Point Ignition

BREAKER POINTS

1. The general condition of the breaker points should be checked as outlined in "General Information" and the points replaced if pitted or worn beyond repair.

CONDENSERS

1. Condensers are best checked with a capacitance tester. Capacitance should be 0.18 mf for 250–400 machines, and 0.22 mf for the H1. If less, replace the condenser.

2. If no special test equipment is available, the condenser(s) may be checked for a short circuit with a low voltage DC test light. Disconnect the condenser wire from the point terminal. Check for continuity between the condenser lead and the condenser body. There should be none. If continuity exists, the condenser must be replaced. Even if there is no continuity, however, this does not guarantee that the condenser is in working order, as there are other things which might be wrong with it, such as partial insulation breakdown.

3. Points which pit, burn, or rapidly wear out would indicate a bad condenser. Check point operation by observing them with the engine running. Noticeable sparking or arcing between the breaker point contact surfaces indicate a bad condenser.

IGNITION COILS

1. A defective ignition coil is most easily found by comparing the performance of the three coils.

2. Remove the spark plug leads from the plugs. Insert a metal pin or nail into each of the plug leads in turn and hold the nail about an eighth of an inch from the cylinder head while kicking over the engine. In each case a fat, blue spark should be produced. If one of the coils produces a spark noticeably weaker than the others, it must be replaced.

3. An ohmmeter or continuity light can be used to check the primary winding of the ignition coil. Disconnect the coil low tension terminals and connect the tester across them. There must be continuity. An ohmmeter should show a relatively low resistance, not more than a few ohms at most. If any one coil has a primary winding resistance higher or lower than the other two, it should be replaced.

4. An ohmmeter can be used to check the resistance of the ignition coil secondary winding. Resistance should be about 10K Ω. If any one coil shows a resistance different from the other two, it should be replaced. Secondary winding resistance is checked by connecting the meter leads to the high-tension lead and to a low-tension terminal. All coil leads should be disconnected while testing.

CDI (H1/A–D)

The following points should be noted on H1 models with battery/CDI:

a. If the battery is installed incorrectly (i.e., connections reversed), the CDI components will be burned out as soon as the ignition is switched on. Exercise extreme care when connecting the battery;

b. Do not connect or disconnect the battery at any time that the ignition switch is on or the engine is running. This will damage the rectifier. A burned-out diode will completely drain the battery if the machine is run.

c. Battery connections must be kept clean and tight at all times.

d. The wiring between CDI units "A" and "B" (refer to wiring diagram) must be properly connected, free of damaged insulation, loose connections, etc. If trouble is traced to the wiring between the units, the units must be checked since they may have been damaged.

e. The black ground wires from the CDI units must be well grounded, or a no-spark condition will arise.

f. The CDI units are sealed, and no repairs can be effected; if damaged, the units must be replaced.

g. The rubber mounts for the CDI units must be in good condition. The units are very susceptible to damage from vibration.

TESTING

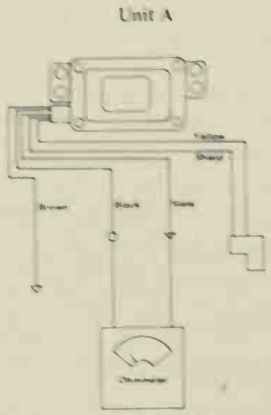
1. Before attempting to troubleshoot a CDI system, first check the above points for possible causes.

2. If spark is absent from only one plug, the trouble is either a defective plug or plug lead.

3. Check the ignition timing and the signal generator rotor-to-pickup coil gap as directed in "Tune-Up."

4. Check the condition of the plug leads. Replace them if damaged, cracked, etc.

5. Check the condition of the distributor cap. If the cap is cracked or chipped in any way, it must be replaced.



6. Disconnect the pickup coil leads at the connector and use an ohmmeter to measure the resistance between the leads. Resistance should be 300–400 Ω. If the correct resistance is not obtained, check the condition of the pickup coil wires, or replace the unit if necessary.

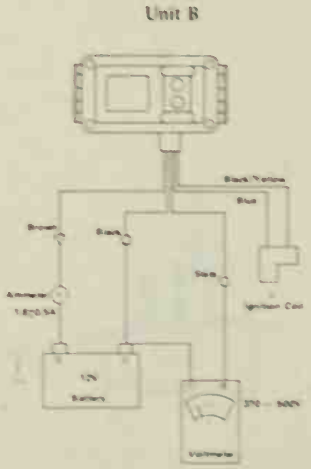
Checking the resistance of the pickup coil

7. To test the CDI "A" unit, an ohmmeter can be used. Disconnect the unit leads. Connect the positive ohmmeter lead to the "A" unit black lead, and the negative meter lead to the unit's gray (or slate) lead. The ohmmeter must show infinite resistance (no continuity).

Connect the positive lead of the meter to the gray unit lead, and the negative meter lead to black unit lead. Resistance must be infinite.

Testing unit "A" with an ohmmeter

These tests are checks for proper operation of the thyristor. If readings are not infinite in both cases, the "A" unit must be replaced.



8. To check CDI unit "B," a voltmeter (at least 500v DC), a DC ammeter and a 12v battery are needed.

Make connections as shown in the illustration: one lead of the ammeter to the positive battery terminal and the other ammeter lead to the brown "B" unit lead. Black unit lead to the battery negative terminal, negative battery terminal to the negative voltmeter lead, and positive voltmeter lead to the slate colored "B" unit lead.

All of the following conditions must be met: the "B" unit must emit a high-pitched hum; the voltmeter must read 370–500v; the ammeter must read 1.8 ± 0.5A with no fluctuation of the ammeter needle.

If any one of these conditions is not met, the "B" unit must be replaced.

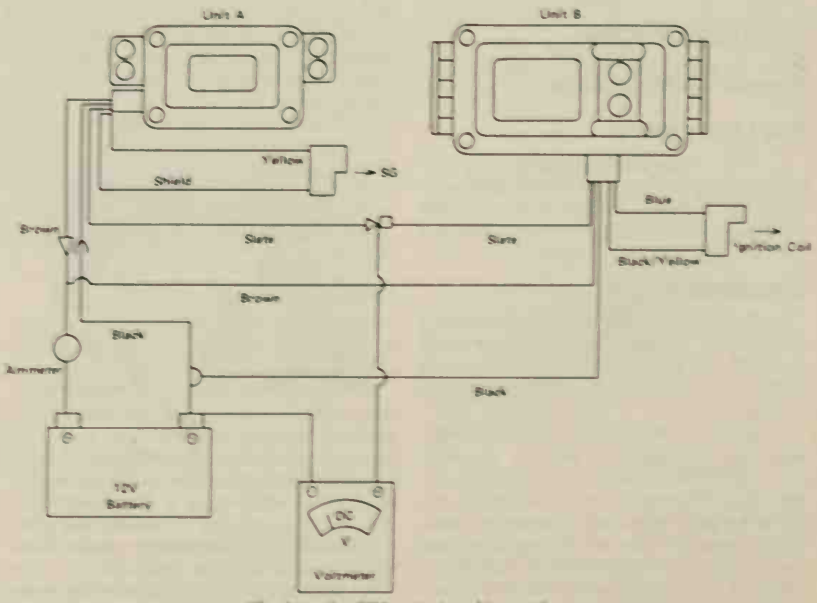
9. Check the units "A" and "B" together as shown in the illustration. All of the following conditions must be met:

Testing unit "B" with an ohmmeter

unit "B" must emit a high-pitched hum; the voltmeter must read 370–500v; the ammeter must read 2.0 ± 0.5A with no fluctuation of the meter needle.

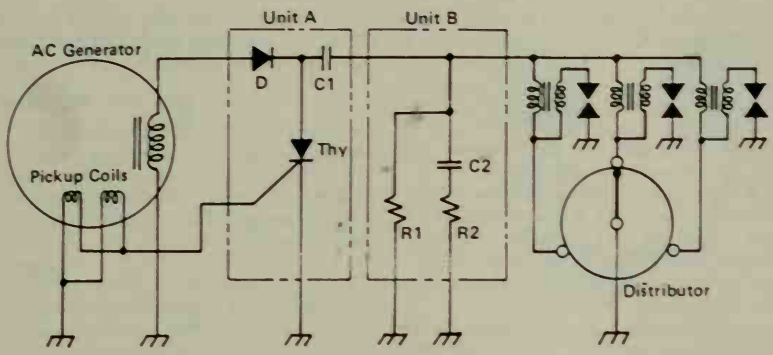
CDI (H1-E,F, KH500)

The CDI system used on these models is fundamentally different from the battery-CDI used on earlier 500s.



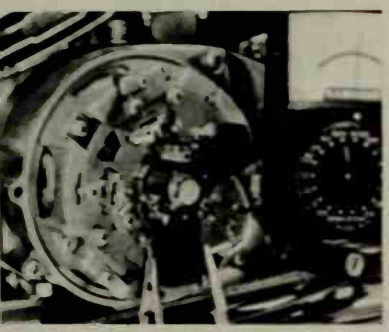
IGNITION WINDING

1. Unplug the brown and orange leads at the connector and check the resistance between them on the alternator side.



2. Resistance should be 115 ohms. If this reading is not obtained, replace the stator.

PICKUP COILS



1. The two pickup coils are connected in parallel. Disconnect the white wires' connector and check resistance between the white wire (alternator side) and ground on the frame.

Checking the CDI units A and B together

H1-E, KH500 electronic-CDI schematic

Testing the pickup coils

2. Resistance should be 130 ohms.

3. If this reading is not obtained, measure the resistance of each pickup coil separately. Unscrew the pick-up coil ground terminal and check resistance between the white wire and the ground wire of each coil. Resistance in each case should be 260 ohms. Replace any coil if resistance is not very close to this value.

DISTRIBUTOR

Refer to "Charging System," following for distributor rotor tests.

CDI UNITS

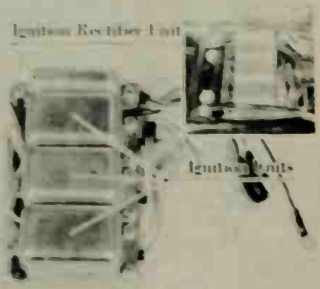
1. There are two CDI units, designated "A" and "B" for test purposes. The units are located at the left rear of the battery, unit "A" being the larger of the two and on the bottom. Connectors are accessible beneath the seat.

2. To test unit "B," disconnect the yellow leads which connects it to unit "A". Check the resistance between the unit "B" yellow lead and the frame ground terminal.

3. Resistance should be 300 ohms. If not close to this reading, replace unit "B"

4. Unit "A" must be checked with a Kawasaki Electrotester. Unplug the brown and orange leads from the unit, and the red/white and white leads. Connect the tester harness to these leads as follows: tester yellow/red to orange; tester brown/red, to brown; tester white to white; tester red/white to red/white; tester black to ground. Turn on the tester (110AC) and turn the motorcycle's ignition to on and the stop switch to "run." The tester pilot light should flash on and off. If it does not, replace the unit.

CDI (H2)



Before attempting to troubleshoot this system, the cause of the problem must be narrowed down as much as possible. Refer to the "Magneto CDI Troubleshooting" chart. Component test procedures are given below.

NOTE: *Do not run the motorcycle with the battery disconnected, as this may cause the ignition units to break down.*

1. Check for spark at each plug. A strong blue-white spark should be produced in each case. If there is no spark or weak spark at one plug, check that plug, its lead, and its ignition coil.

2. If there is strong spark at all three plugs, yet the engine will not start, check that the plug leads are connected to the correct plugs. If they are, the problem is not in the electrical system, unless the ignition timing is quite far off the mark.

3. A faulty ignition unit for any one cylinder may cause a no-spark condition at all three. To check the ignition units, disconnect the three light green wires going from the ignition rectifier unit to the ignition units. Connect one wire at a time to its proper ignition unit and check for spark at that cylinder. If spark is evident at two cylinders only, the ignition unit for the dead cylinder is defective.

Ignition and ignition rectifier units (H2)

4. If spark is absent from only one cylinder, and the plug and lead is in good condition, follow the procedure below to isolate the problem. The source of the problem must be one of the following: the ignition coil, the ignition unit, the ignition rectifier, or the signal generator.

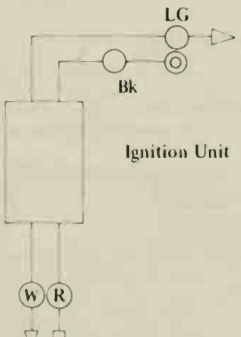
a. Disconnect two of the green wires coming from the ignition rectifier and going to the ignition units, one for the bad cylinder, and one from either of the good cylinders. Reverse the connections. If the bad cylinder shows spark and the good cylinder is now without spark, the problem is a defective ignition rectifier.

Magneto CDI Troubleshooting

Problem	*Possible Causes*	*Inspection, Remedy*
No spark at any cylinder	Wiring connections broken, defective wiring	Check wiring connections and insulation.
	Defective ignition rectifier	Replace.
	AC generator defective	Replace.
	Defective ignition unit	Replace.
Weak spark at all three cylinders	AC generator defective	Replace.
	Ignition rectifier defective	Replace.
Weak spark at one cylinder	Defective plug lead	Replace.
	Defective ignition coil	Replace.
	Defective signal generator	Replace.
No spark at one cylinder	Wiring connection broken	Check wiring connections and insulation.
	Spark plug lead damaged or defective	Replace.
	Defective ignition coil	Replace.
	Defective ignition unit	Replace.
	Defective ignition rectifier	Replace.
	Defective signal generator	Replace.
High-speed misfire although strong spark shows at all cylinders while kicking engine over	Defective spark plug(s)	Replace.
	Ignition timing incorrect	Adjust.
	Carburetor settings wrong	Adjust.
	AC generator high-speed coil defective	Replace.

b. If there is no spark at the bad cylinder, reverse the plug wires of the bad cylinder and either of the good cylinders. Disconnect the red wire from the ignition unit to the ignition coil for the bad cylinder and for the good cylinder whose plug lead you reversed, and reverse the connections. Check for spark. If spark shows at the bad cylinder, the problem is the ignition coil. If there is no spark, proceed to the next test,

c. Connect the plug leads in the normal way, but leave the coil wires reversed. Take the white wire coming from the bad cylinder's ignition unit and switch it with the white wire coming from the good cylinder's ignition unit. If the bad cylinder shows spark, its ignition unit is defective. If it does not, the signal generator coil is defective.



Be sure to connect all wiring in the proper manner after testing has been completed. Check ignition timing as described in Chapter 3 if a signal generator coil has been replaced.

OHMMETER TESTS

All CDI system components can be checked with an ohmmeter.

Ignition Unit

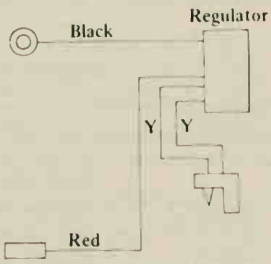
1. Using the R x 10 range of the ohmmeter, check the resistance between the black and the light green ignition unit leads. With the positive meter lead connected to the black lead, resistance should be infinite (no reading). With the positive meter lead connected to the light green lead, resistance should be infinite. If the readings are not correct, the ignition unit is defective and must be replaced.

Ignition unit leads (H2)

2. Using the R x 100 range of the ohmmeter, check the resistance between the light green and the red ignition unit leads. Connecting the positive meter lead to the light green unit lead and the negative meter lead to the red lead, the ohmmeter needle should jump and then indicate infinite resistance. Reversing the connections should show the same reaction. If the meter does not react properly, the ignition unit is defective.

Ignition Rectifier

1. Using the R x 10 meter range, test the ignition rectifier by checking resistance between the black/white lead and the blue, white, and green leads in turn. If the positive meter lead is connected to the black/white wire and the negative lead is connected to the others one at a time, a resistance of about 35 Ω should be obtained between the black/white, the blue, and the green leads, and a resistance of about 90 Ω between the black/white and the white leads.



If the negative ohmmeter lead is connected to the black/white wire, and the test repeated, an infinite resistance should be obtained in all three cases. If the readings are not correct, the ignition rectifier is defective.

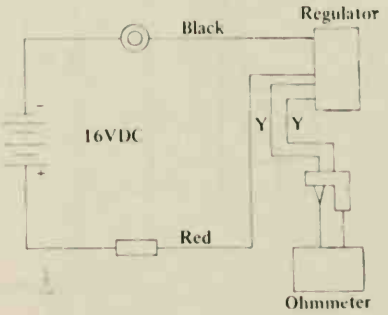
2. Using the R x 10 range, measure the resistance between the black/white lead and each of the light green leads one at a time. With the positive meter lead connected to the black/white lead and the negative to the light green leads, an infinite resistance should be indicated in all three cases. If the negative meter lead is connected to the black/white wire, and the positive to the light green wires, a resistance of about 35 Ω should be obtained in all three cases. If the readings are not correct, the ignition rectifier unit is defective.

Regulator/Rectifier

This unit accomplishes the dual purposes of voltage rectification (AC to DC) and voltage regulation. It functions in both ignition and charging circuits. The following tests may therefore determine the cause of a fault in either circuit.

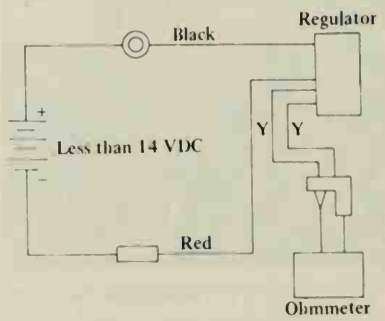
1. To test this unit, use the R x 10 meter scale and measure the resistance across the black and the red leads. If the positive ohmmeter lead is connected to the black regulator lead, a resistance of

Regulator unit leads



about 70 Ω should be obtained. If the connections are reversed, a resistance of about 1K Ω should be indicated.

2. Check the resistance between the black lead and each yellow lead, one at a time. If the positive meter lead is connected to the black regulator lead, a resistance of about 25 Ω should be obtained in each case. If the negative meter lead is connected to the black regulator lead, the resistance in each of the two cases should be about 1K Ω.



3. Check the resistance between the red lead and each of the yellow leads in turn (R x 10 range). Connecting the positive meter lead to the red wire should yield a resistance of 1K Ω at one yellow lead, and about 4K Ω at the other yellow lead.

Connecting the negative meter lead to the red wire should yield a resistance of about 25 Ω across each yellow lead.

4. Connect a 16v DC power source across the regulator black and red leads (positive battery terminal to the red lead).

Checking the regulator

Regulator test

Check the resistance across the yellow leads. Resistance should be infinite one way, and about 500 Ω when the ohmmeter leads are reversed.

5. Connect a DC source less than 14v across the black and the red regulator leads (positive battery terminal to the black lead), and connect the ohmmeter across the yellow regulator leads. Resistance should be infinite, and if the meter connections are reversed, an infinite resistance should also be obtained.

If the regulator fails any of the above tests, it is defective.

AC Generator

The generator should be tested at normal operating temperature, but not when it is hot from operation.

1. Check the resistance between the two yellow leads. It should be 0.4 Ω.

2. Check the resistance between each yellow lead and ground. Resistance should be infinite.

3. Resistance between the blue and the green alternator leads should be about 5.0 Ω.

4. Resistance between the black generator wire and each of the white leads, in turn, should be 200 Ω. This tests the signal generator.

If readings are not correct, the alternator is defective.

Ignition Coil

1. Resistance between the white coil lead and the coil core should be about 0.8 Ω.

CHARGING SYSTEM

S-Series, KH 250

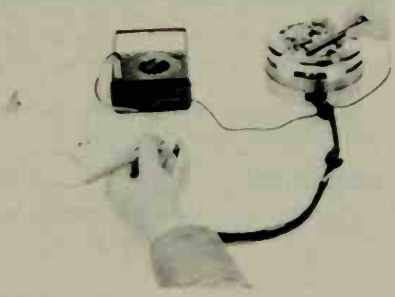
The purpose of the charging system is to supply power to the battery to run the lights, horn, etc., as well as the ignition circuit, although the power required by the accessories is much greater than that used by the ignition coils and spark plugs.

The charging system consists of an AC generator (or alternator), a rectifier, and a voltage regulator.

The alternator consists of a permanently magnetized rotor, attached to the crankshaft, which turns inside a housing (or stator) to which three coils are attached, 120° apart. The coils are wired as shown in the illustration. As the magnetic rotor turns, a current is generated in the coils, the amount of which varies proportionally with the speed of rotation: the higher the rpm, the higher the output. This current is the alternating type. It is changed to direct current by the rectifier in order to charge the battery.

The output of the alternator must be controlled so that the battery is not overcharged when the machine is operated consistently at high rpm, or discharged when operated with a load on the system (lights, etc.). This control is accomplished by the voltage regulator, in this case a zener diode. When the output of the alternator exceeds the voltage required by the battery, the zener diode allows the excess to flow to ground.

1. In the event of charging system failure, the battery itself should be checked first. If the battery will not hold a charge or overcharges, test each cell with a hydrometer.
2. If the battery is in good condition, check that all electrical connections in the circuit are clean and tight.
3. If the battery overcharges, suspect the voltage regulator.
4. If the battery discharges, suspect the alternator, the rectifier, or the regulator.



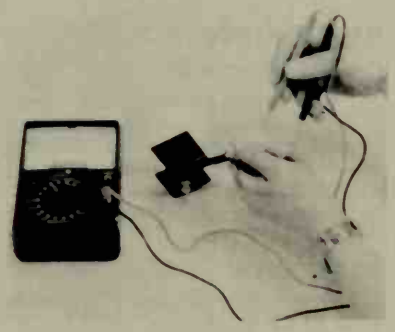
ALTERNATOR

Alternator tests can be carried out with an ohmmeter.

1. Disconnect the alternator connectors at the voltage regulator and the rectifier. Check for continuity between the yellow, the pink, and the white leads testing two leads at a time. There should be continuity between all three because the coils are all connected. If there is no continuity between any two wires, the assembly must be replaced.

Checking for continuity between the stator leads

Checking for continuity between the stator leads and the housing



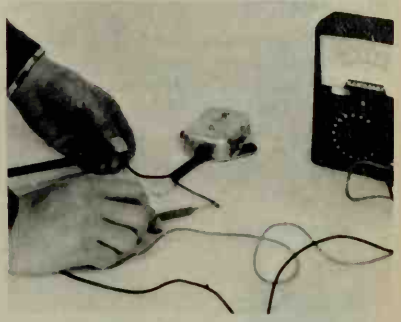
2. Check for continuity between each lead and the housing. There must be no continuity. If there is in any case, the assembly must be replaced.

RECTIFIER

The rectifier can be checked with an ohmmeter or continuity light.

1. Disconnect the rectifier wiring at all points.
2. Hook up the negative tester lead to the black rectifier wire, and the positive lead to each yellow lead, one lead at a time. Note whether or not there is continuity. Current must either flow or not flow in all three cases. Now switch the tester leads so that the negative lead is connected to the yellow and the positive to the rectifier black lead and repeat the tests. In each case there must be continuity or no continuity all three times.

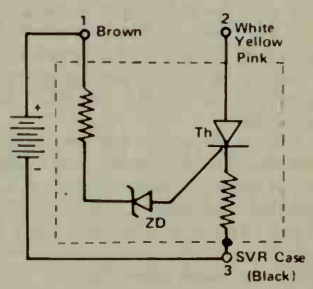
Now compare the two sets of tests. If there was current flow in the first series, there must be none in the second. If there was no current flow in the first series, there must be flow in the second. In other words, current must flow through the rectifier in one direction only. If both series showed continuity, or if neither of them did, the rectifier is defective.



Testing the rectifier

REGULATOR

The voltage regulator can be checked with an ohmmeter.



1. Disconnect the regulator wires and remove it from the motorcycle.
2. Check the resistance between the brown and the black lead. It should be more than 1K Ω.
3. Check for current flow in both directions between each of the regulator leads (white, yellow, pink) and the black lead.

Testing the voltage regulator

There should be no continuity shown in either direction.

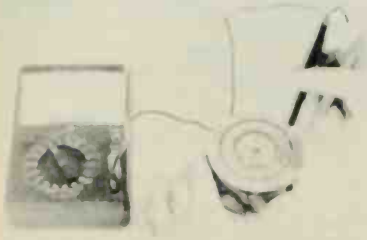
4. Connect a 12v battery positive battery terminal to the brown lead, and negative battery lead to the black lead. Check that there is no current flow from the black to the brown lead.
5. Wire another battery in series with the first so that the total input is over 16v. Check for current flow from the brown to the black lead. If there is flow, the regulator is operating correctly.

Regulator test set-up

When handling the voltage regulator, obey the following precautions:

1. Do not connect or disconnect the regulator unless the ignition switch is turned off.
2. The regulator mounting screws must be secure at all times, and all wiring must be correct.
3. A dead or almost dead battery will not allow the regulator to function properly. Check battery condition and charge or replace it as necessary.

H1/A-D



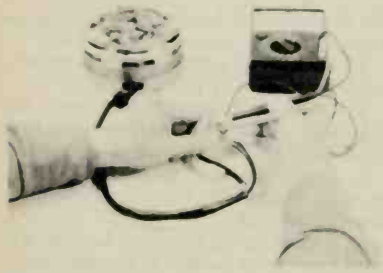
Both breaker point and CDI models are fitted with an alternator to charge the battery. The alternator consists of an electromagnetic rotor which turns inside a housing to which three sets of coils are attached. The movement of the magnetic field of the rotor through the coils generates an alternating current in them. The current is changed to direct current by the rectifier and used to charge the battery.

The amount of electrical power generated by the alternator is determined by the voltage regulator. This device maintains a voltage of 14.5 volts across the battery at high speed. The regulator varies the strength of the rotor's magnetic field. When field strength is high, alternator output is high, and vice versa, at a given rpm.

ALTERNATOR

The alternator can be tested with an ohmmeter.

1. Remove the alternator stator and rotor from the machine.



Checking for resistance between the alternator slip rings (H1)

2. Check the resistance between the rotor slip rings. Resistance should be 3.5–5.5 Ω. If resistance is lower than this amount, the rotor field coils are shorted. If infinite, there is an open circuit. In either event, the rotor must be replaced.

3. Check the condition of the rotor slip ring carbon brushes. The length of new brushes is 14 mm. If the length of the brushes is less than 9.5 mm, they should be replaced.

4. Check for continuity between each of the three yellow leads, two leads at a time. (If the leads were numbered, 1, 2, 3, check for continuity between 1–2, 1–3, and 2–3.) There must be continuity in all cases. If any test shows an open circuit, replace the stator assembly.

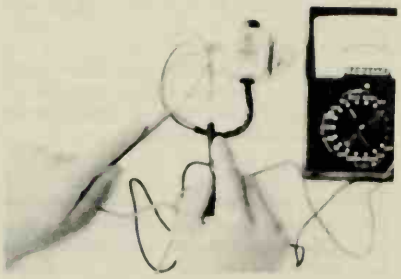
Checking for continuity between the stator leads

5. Check for continuity between the stator housing and each of the yellow leads. Resistance should be infinite. If there is current flow in any case, replace the stator assembly.

RECTIFIER

The rectifier can be checked with an ohmmeter or continuity light.

1. Check for continuity between each of the rectifier leads after removing it from the machine.



Yellow (3) to Black
Blue to Black
Red to Black
Blue to Yellow (3)
Red to Yellow (3)

In each case, there should be current flow when the tester leads are hooked up to each set of leads indicated above, but no current flow when the tester leads are reversed. Continuity in both directions or no continuity in either direction for the pairs of leads indicates a defective rectifier.

NOTE: *Be sure to test all three yellow leads and the other lead where shown.*

REGULATOR

An ohmmeter or a DC voltmeter can be used to check the regulator.

Checking the voltage regulator

1. After removing the regulator from the machine, measure the resistance between the brown and the black leads. Resistance should be 53–55 Ω. If the resistance is not within 10% of this value, replace the regulator.

2. Install the regulator on the motorcycle, secure it, and be sure that all connections are correct. Start the engine and rev to 5,000 rpm. At this point a voltmeter connected to the positive battery terminal and ground should indicate 14–15 volts. If voltage is incorrect, replace the regulator.

NOTE: *This test assumes that the battery and the alternator are in good condition. Check them first before replacing the regulator.*

H1–E/F, KH500

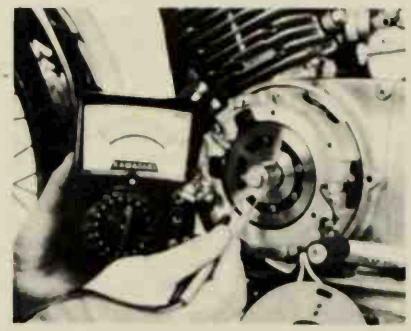
CHARGE WINDINGS

1. Disconnect the two yellow wires at the two-lead plug, and check resistance (on the alternator side of the circuit) between the two yellow wires. It should be about 0.25 ohms.

2. If this reading is not obtained, the stator must be replaced.

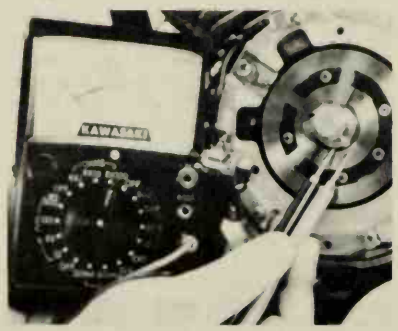
DISTRIBUTOR

1. Remove the alternator cover and the plate for the brushes and pick-up coils.



2. Clean the slip rings thoroughly.

3. Check the resistance between the outer ring and the separated section of the inner ring. Resistance should be infinite. If not, replace the rotor.



4. Check resistance between the inner ring and the rotor shaft. Again, resistance must be infinite or replacement of the rotor is necessary.

BRUSHES

1. A wear-limit line is marked on each brush and they should be replaced when worn to this mark.

Checking resistance between the inner and outer slip-rings

Checking resistance between the inner ring and the rotor shaft

REGULATOR

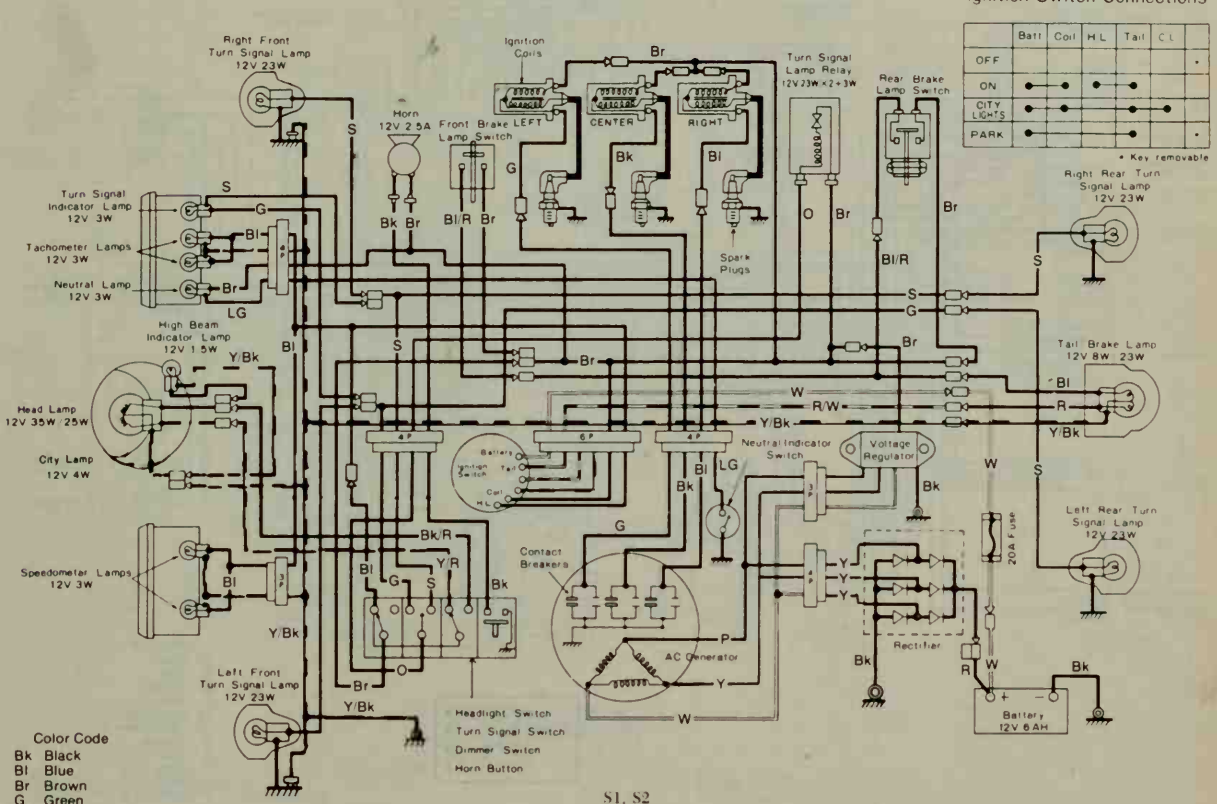
1. The regulator may be checked in place on the motorcycle. For the test to be valid, the battery must have a charge of at least 13v.

2. The regulator is mounted inside of the left side cover. Disconnect the red lead from the regulator and connect the positive lead of an ammeter (12a range) to the red lead coming from the regulator and the negative tester lead to the red lead from the battery.

3. Connect a 30v DC voltmeter, positive lead to the battery positive terminal, negative lead to the battery negative terminal.

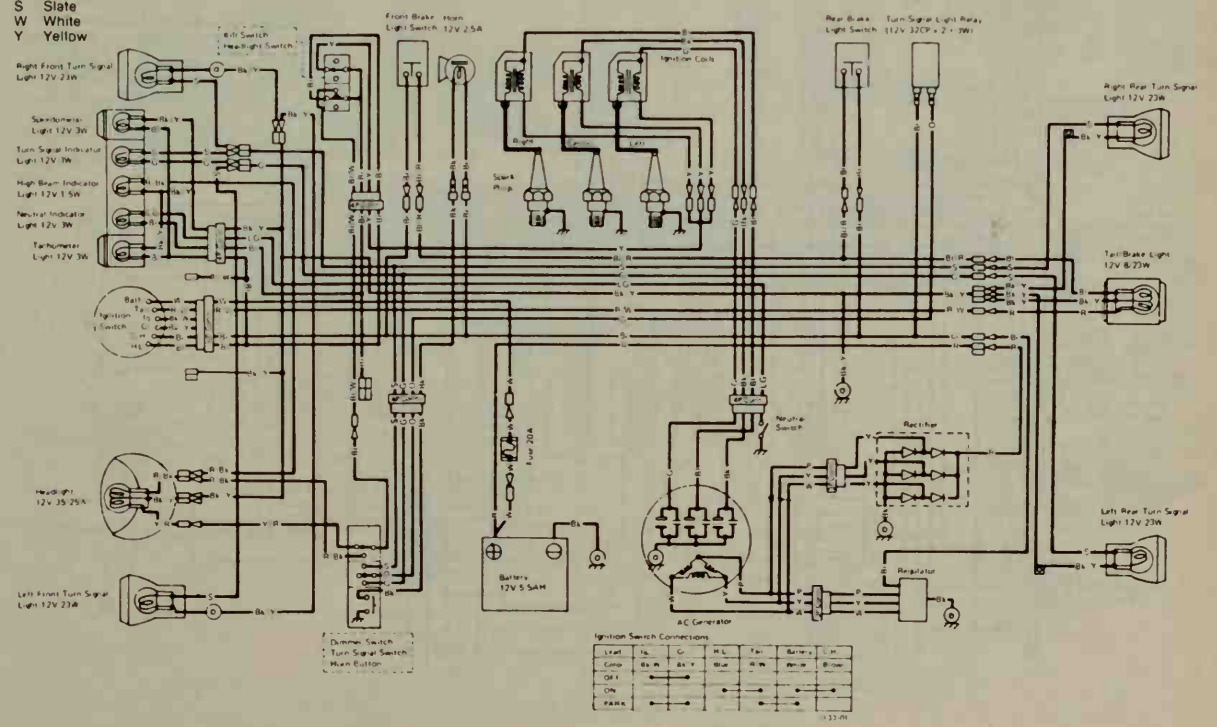
4. At idle, current should be less than 2a, and voltage 14.5–15.5v.

5. At 3,000 rpm, readings should be the same.



6. With the headlight on low-beam, and at idle, current should be less than 5a, voltage 12–13v. At 3,000 rom, current should be unchanged, and voltage 14.5–15.5v.

7. Assuming that the alternator, battery, etc., are in good condition, the regulator is defective if these readings are not obtained.



H2

Tests for the H2 charging system components are included in the preceding "CDI (H2)" section, due to the construction of this motorcycle's electrical system. The "magneto" or alternator which powers the ignition circuit also charges the battery after its output is changed to direct current by the rectifier. The rectifier also accomplishes voltage regulation. This is not to be confused with the "ignition rectifier" which functions only in the ignition circuit.

H1-E/F, KH500

WIRING DIAGRAMS

H2

H2-B/C

CHASSIS

WHEELS, BRAKES

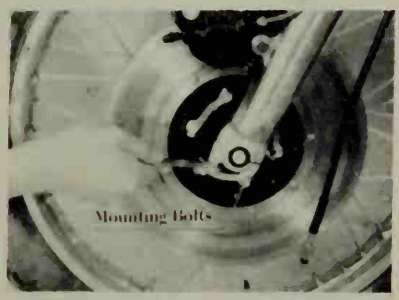
Front Wheel Removal and Installation

FRONT DRUM BRAKE

1. Support the front wheel off the ground by placing a crate or another suit able object beneath the engine.
2. Disconnect the brake cable from the brake lever and the brake plate.

Disconnecting the speedometer cable

3. Remove the speedometer cable from the brake plate after removing the inner cable securing bolt.
4. Remove the cotter pin from the axle and remove the axle nut. Loosen the fork slider pinch-bolt.
5. Withdraw the axle, and remove the front wheel assembly.



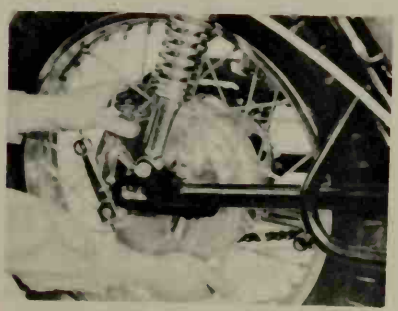
Loosening the axle pinch bolt

6. To install, hold the front wheel assembly between the fork legs with the slot in the brake plate engaged with the tab on the fork slider, and slip the axle into place.
7. Hold the axle from turning with a phillips head screwdriver, and install the flat washer and axle nut. Torque the axle nut to 48–61 ft lbs then back the nut off until a slot in the nut lines up with a hole in the axle. Install a new cotter pin to secure the axle nut.
8. Tighten the axle pinch-bolt located on the bottom of the fork slider.
9. Install the front brake cable and adjust the cable.

FRONT DISC BRAKE

1. Place a crate or another suitable object beneath the engine so that the front wheel is raised at least 2 in. off the ground.
2. Unscrew the speedometer cable from the drive housing on the brake plate.

Removing the axle capnuts



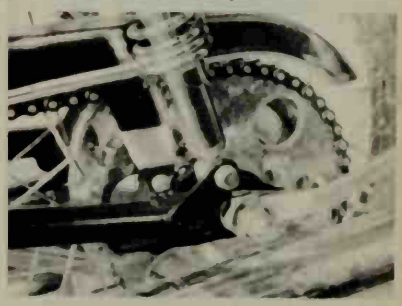
3. Remove the two bolts from each of the axle caps and remove the front wheel.
4. To install, hold the wheel in place and replace the axle caps. Do not tighten the caps at this time.
5. Fasten the speedometer cable to the drive housing, and position the drive housing so that the speedometer cable does not have any sharp bends. Then tighten the axle caps.

CAUTION: *The axle caps are machined unevenly (one side is slightly higher than the other) the high side MUST face the front. The front bolts should also be tightened first starting on the disc side so that a small even gap exists between the bottom of the fork slider and the rear of the axle cap. If in doubt which side is the high side, place a straightedge across the top of the cap; the high side should be apparent. On late models, the caps are marked with an arrow which must point towards the front of the motorcycle.*

Rear Wheel Removal and Installation

250–500

1. Remove the right pair of mufflers by loosening the connection at the header pipe and removing the front muffler mounting bolt and the right rear footpeg.
2. Unscrew the brake adjuster nut. Depress the brake pedal and disconnect the brake cable or rod from the brake plate lever. On cable-operated brakes, disconnect the cable from the brake lever and disconnect the cable adjuster from the holder on the brake plate. Remove the spring (if fitted) and place it along with the adjuster nut and clevis pin in a safe place.



Removing the rear wheel

3. Loosen the chain adjuster locknut on each adjuster. Then back off the adjuster bolts to allow some free-play of the rear wheel. Remove the cotter pin from the axle. Disconnect the brake anchor from the brake plate.
4. Remove the axle nut, axle, and right chain adjuster. The wheel can now be removed leaving the sprocket in place.
5. To install, place the rear wheel in position and install the right chain adjuster and the axle.
6. Adjust the chain.
7. Connect the brake anchor to the brake plate, tighten the nut firmly and install a new cotter pin. Tighten the axle nut to a torque of 48–61 ft lbs.
8. Connect the brake cable or rod to the brake lever and brake plate, adjust the brake.

750

1. Remove the right pair of mufflers by loosening the connection at the header pipe, and removing the front muffler mounting bolt and the right footpeg.
2. Remove the cotter pin and nut from the brake anchor and separate the brake anchor from the brake plate.

Removing the axle nut (H2)

3. Remove the cotter pin and axle nut from the axle.
4. Loosen the chain adjusters so that the wheel can be moved forward and the chain lifted off the sprocket.
5. Remove the axle. The wheel assembly can now be removed.

Lifting the chain off the sprocket (H2)

6. To install the wheel assembly, wrap the chain around the sprocket. Hold the chain adjusters and wheel in place, and slip the axle through.
7. Adjust the chain free-play. Connect the brake anchor to the brake plate, and install a new cotter pin.
8. Tighten the axle nut to a torque of 83.2–90.4 ft lbs, then back it off until a

slot in the axle nut is in line with a hole in the axle. Install a new cotter pin.

9. Connect the brake rod to the brake lever, and adjust the brake pedal free-play.

Sprocket Assembly

The rear sprocket assembly consists of the sprocket, sprocket hub, sprocket hub bearing, and the rubber dampers which will remain in the wheel when it is removed.

REMOVAL AND DISASSEMBLY

1. Disconnect the drive chain. Unscrew the large sprocket hub nut and remove the assembly from the swing arm.

2. Bend down the tabs on the sprocket nut locking plates. Unscrew the nut and remove the sprocket from the hub.

Removing the sprocket hub

3. To remove the hub bearing, first remove the sprocket shaft by tapping it out from the sprocket side of the hub. Use a plastic mallet or block of wood so that the sprocket shaft threads will not be damaged when struck.

4. Take off the sprocket shaft collar.

5. Use an elbow-shaped tool to pry out the oil seal. If the oil seal is damaged on removal, as is likely, a new one must be fitted.

6. Drive the bearing out toward the sprocket side of the hub with a suitable drift or bearing driver. Tap the bearing evenly around its circumference to avoid distorting the hub.

INSPECTION

1. For bearing inspection and lubrication, refer to "Wheel Bearings," below.

2. Check the condition of the sprocket. If the sprocket is warped, or if the sprocket teeth are worn or hooked, the sprocket should be replaced along with the chain and the countershaft sprocket.

3. Check the condition of the sprocket nuts, bolts, and locking plates. Replace any nuts or bolts with rounded flats, stripped threads, or those which are bent or cracked. Bolts must be tightened securely upon installation. It is also recommended that they be secured with a thread locking compound. The locking plates must not have fatigued or cracked edges, since these are used to lock the nuts in place. Replace the plates if damaged in any way.

4. Check the condition of the oil seal and replace it if the lips are damaged.

5. Inspect the sprocket shaft for broken or stripped threads.

6. Check the condition of the rubber dampers in the wheel hub. These take up any driveline shocks when the clutch is released and have an important effect on chain and sprocket life. Replace any damper which is hardened, crushed, or damaged.

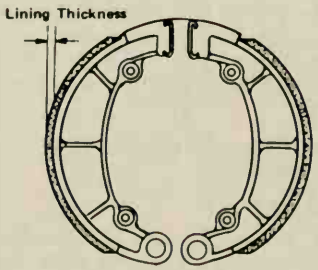
In instances where the damper is a tight fit in the hub, some engine oil or dishwashing liquid can be used to facilitate removal and installation.

ASSEMBLY

1. Assembly is the reverse order of disassembly procedure.

2. Lubricate the bearing as described in "Wheel Bearings," below. The bearing should be driven into place with a bearing driver or a suitable substitute.

3. Grease the lips of the oil seal before installation. The seal should be pressed into the hub with care.



4. Tap the sprocket shaft into the hub from the wheel side.

5. When connecting the chain masterlink, install the spring clip closed end facing the direction of chain rotation. Tighten the sprocket hub nut securely.

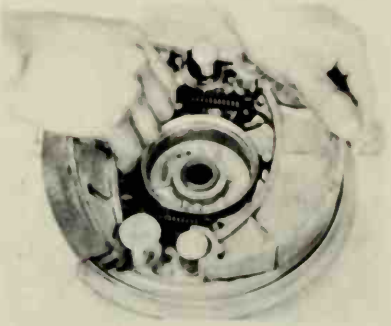
Drum Brake Service

All models use a single-leading shoe rear brake, while, a twin-leading shoe is used on the front brake. Kawasakis use brakes in which the lining is bonded to the brake shoe, therefore, are purchased and replaced as a single unit.

1. Brakes can be inspected in place on the brake plate.

Check lining thickness

2. Inspect the shoes for wear. There should be at least 0.12 in. (3 mm) of lining material left (measured at the lining's thinnest point) or the shoes must be replaced.



3. Use a large vernier caliper to measure the inside diameter of the brake drum. If the diameter is found to be less than the service limit given in the "Chassis Specifications" chart, the hub should be replaced.

4. Inspect the linings for scoring or grooves. These may be caused by particles of dirt which have entered the drum. If badly scored, the shoes should be replaced. If scoring of the shoes is evident, it would be wise to inspect the brake drum for the same type of damage.

Be sure that there is no oil or grease present on the brake linings. Oil-impregnated linings must be replaced. If the linings do show this condition, determine the source of the lubricant: defective wheel bearing oil seals, excessive chain lube, etc.

5. If the linings are usable, rough up the surface with a piece of coarse sandpaper. Then clean the linings thoroughly with alcohol or laquer thinner. Clean the brake drum with the same solvent.

6. To disassemble the brake plate, simply grasp each shoe and fold them toward the center of the brake plate. They may be installed in the same manner.

Removing the brake shoes from the brake plate

7. Remove the brake lever pinchbolt(s) and pull the lever(s) off the splined brake camshaft(s).

NOTE: *The plurals refer to the twin-leading shoe brakes.*

8. Push the brake cam(s) out of the brake plate from the outside using handpressure or by tapping with a plastic mallet. Remove the dust seals (if fitted) from the brake plate.

9. Check that the brake lever pinchbolts are not bent. This can easily happen if they are overtightened. Replace any bolts which are in this condition. Inspect the brake lever splines and replace the lever(s) if these are worn or torn.

10. Inspect the splines on the brake cam(s). These should be in good condition. Check that the brake cams are not bent and that they can rotate freely in the brake plate passage. If it will not, use a fine grade of sandpaper on the camshaft and the surface of the brake plate passage.

11. Clean the cam(s) thoroughly in a solvent to remove any old grease, rust or corrosion. Use sandpaper or emery cloth to polish the cams. Clean off any residue; before reassembly, smear the cams with chassis grease.

12. Inspect the brake plate for cracks or fractures, and replace it if necessary.

13. On twin-leading shoe brakes, the brake plate linkage should be checked. The connecting rod is secured to each brake lever by a clevis pin and cotter pin. These pins can be removed after the cotter pin is taken off. They should be checked for wear, especially on high mileage machines, and replaced if necessary.

14. Check the condition of the brake springs, noting any twisted or fatigued hooks. Replace any broken, rusted, or old springs with new ones. Be sure that the lever springs are in good condition. Check the length of the brake springs against the specification given in the "Chassis Specifications" chart.

15. Clean all parts thoroughly with a suitable solvent, making a special effort to remove the dust and built-up dirt from the brake plate.

16. When reassembling the hub, note the following points:

a. Ensure that the brake cams are lubricated with chassis grease and that any shims which were on the cams are in place;

b. The use of new dust seals is recommended;

c. Lubricate the brake shoe pivot points with a little grease;

d. Install the shoes as on removal. Hook them together with the springs, and fold them down over the brake cam(s) and pivot(s).

On twin-leading shoe brakes, position the front brake lever so that it forms a 90° angle with the brake cable when the shoe begins to contact the drum. Position the rear lever parallel to the front lever. Adjust the linkage as described in "Maintenance."

Brake Drums

1. Upon disassembly of the hub, inspect the brake drum surface for condition. The drums must be clean and free from score marks or rust.

2. Rust can be removed from the drum surface with sandpaper. Polish the surface until it is shiny, then clean it thoroughly.

3. Alcohol or lacquer thinner can be used to remove dirt or deposits from the drum.

4. The drum should be checked for concentricity. An out-of-round condition is usually noticeable as an on-off-on feeling when the brake is applied while riding. With the wheel assembly mounted on the machine, spin the wheel while applying the brake very lightly. The rubbing noise of the brakes against the drum should be heard for the entire revolution of the wheel.

5. An out-of-round condition and most scoring can be removed by having the drum turned on a lathe. If the rim needs to be trued, have this done before any work on the drum is performed, as the action of the spokes while truing the rim may further aggravate the drum warpage.

Disc Brake Service

When handling disc brake fluid, observe the following cautions:

a. Brake fluid absorbs moisture very quickly, and then becomes useless. Therefore, never use fluid from an old or unsealed container;

b. Brake fluid will quickly damage paint. Place a protective cover on the gas tank;

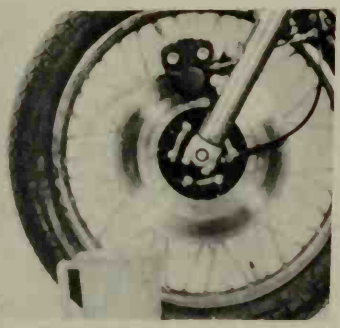
c. Use only DOT #3 or DOT #4 brake fluid.

FLUSHING

The brake system should be flushed out every 8,000 miles, or once a year.

1. Attach a length of vinyl tube to the bleed screw on the brake caliper, and put the other end into a small container.

2. Remove the master cylinder cap, and the diaphragm. Loosen the bleed screw. Pull the brake lever slowly to the handgrip. Repeat until the master cylinder is almost empty.



3. Add new brake fluid to the master cylinder and continue squeezing and releasing the brake lever until the new fluid begins to come out of the vinyl tube. Bleed the system as outlined below.

BLEEDING

1. Needed for this operation are a torque wrench, a small cup, and a vinyl tube.

2. Be sure that the reservoir is topped up. After checking the reservoir level, replace the diaphragm.

3. Connect the vinyl tube to the bleed screw on the caliper, making sure that it is a tight fit; then insert the other end of the tube into a small container with several inches of brake fluid in it. Be sure that the end of the tube is below the level of the fluid in the container.

Bleeding the front disc brake

4. Apply the brake lever *slowly* several times, then hold it ON.

5. While holding the brake lever on, loosen the bleed screw. The brake lever will be pulled toward the handgrip. Close the bleed screw BEFORE the lever bottoms out on the handgrip.

6. Repeat the procedure until the fluid issuing from the lower end of the tube is completely free of air bubbles.

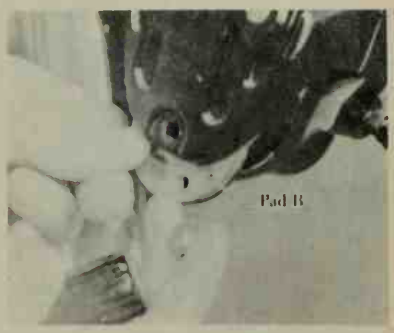
NOTE: *During the operation, keep a check on the reservoir fluid level, maintaining it near its normal position.*

7. Tighten the bleed screw to 4.5–6.7 ft lbs.

8. Top up the reservoir to the level line.

PAD REPLACEMENT

Two-Piece Caliper



1. Remove the front wheel.

2. Remove the phillips head screw from the back of the inside caliper half, and remove the inside pad (pad B).

3. Squeeze the brake lever carefully until the outside pad (pad A) can be removed. Do not force the piston out more than is necessary.

4. Inspect the pads for wear. If either pad is worn past the red line, replace both pads as a set.

5. Inspect the pads for score marks.

Removing the inner brake pad

Minor scoring can be removed with sandpaper. Be sure that there is no oil or grease present on the pads. Fluid-impregnated pads must be replaced.

NOTE: *The pads should always be replaced as a set.*

Open the bleeder valve and push in the outer pad "A"

6. To install, open the bleeder valve slightly to relieve pressure, then push the piston in all the way and close the valve. Be prepared for brake fluid to exit the bleeder valve when the piston is forced in.

7. Install the outside pad (pad A), making certain that the groove in the pad is aligned with the positioning pin.

8. Install the inside pad (pad B), apply thread locking compound to the securing screw and install the screw.

9. Install the front wheel. Check the fluid level in the master cylinder. Note that fitting new pads in the place of a pair which were considerably worn will result in a rise in the reservoir fluid level. If it gets too high, drain off any excess fluid via the caliper bleed screw. If the brake lever feels soft or spongy, the brake should be bled.

10. Avoid hard application of the brake for about 50 miles until the new pads are seated.

One-Piece Caliper

1. Remove the front wheel.

2. Remove the mounting screw for the inner pad (pad B) and take off the metal plate. Remove the pad.

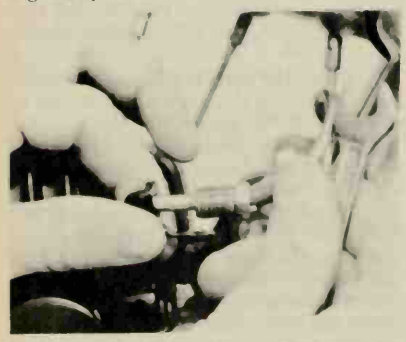
3. Push the caliper body to the right side of the motorcycle and take out the outer pad (pad A). If removal is difficult, gently apply the brake lever until the pad is forced out.

4. Check the pads for wear and replace them, as a set, if either is worn to the red wear limit line.

On one-piece calipers, remove the mounting screw to take out pad B

5. Check for score marks. Minor scoring can be removed with sandpaper. Be sure there is no oil or grease present on the pads. Fluid-impregnated pads must be replaced.

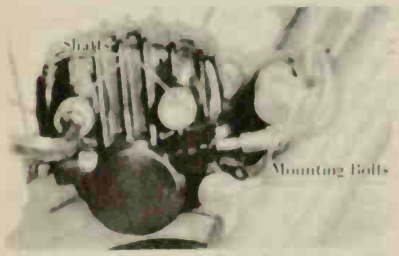
6. To install the pads, loosen the bleeder valve slightly and push in the piston as far as possible. Tighten the valve. Install pad A. Install pad B, aligning the pad tongue with the groove in the caliper. Fit the plate. Secure the screw with a thread locking compound (non-permanent).



7. Check fluid level and bleed front brake.

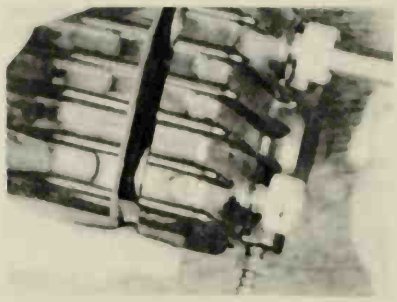
8. If new pads are fitted, avoid hard application of the brake for about 50 miles.

TWO-PIECE CALIPER



Removal and Disassembly

1. Disconnect the brake line pipe from the caliper half, place the rubber cap from the bleeder valve over the end of the brake line to prevent dirt from entering the system.



Plug the end of the brake line with the bleeder valve cap to prevent fluid loss

2. Loosen the two allen head shafts a few turns. Remove the two mounting bolts holding the caliper to the fork slider, and remove the caliper.

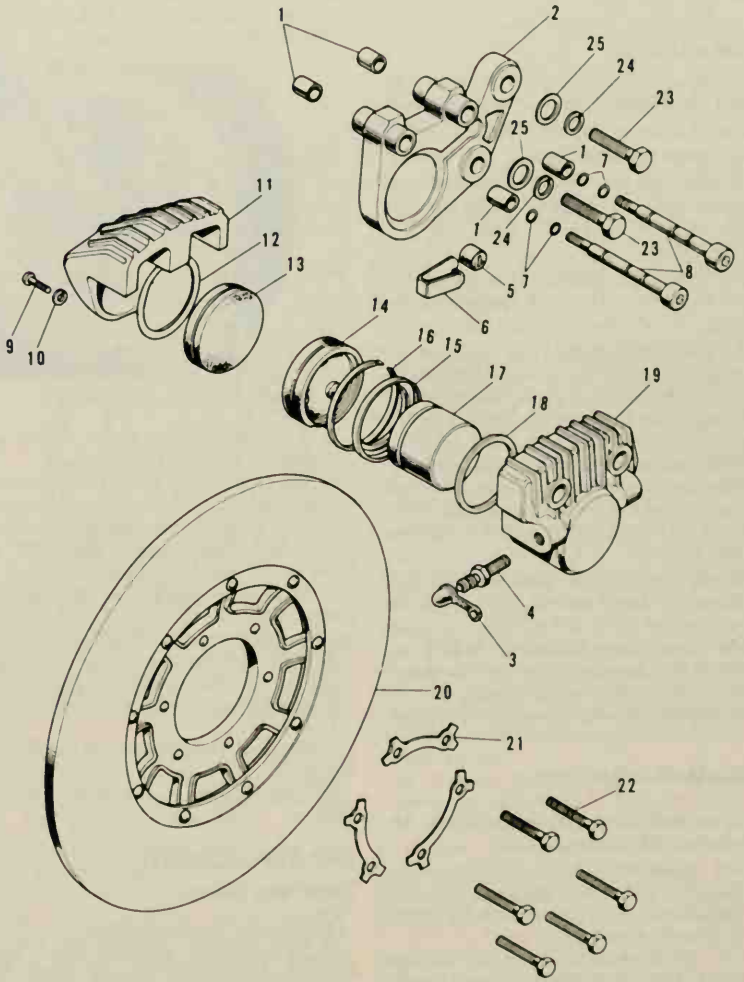
Loosen the allen bolt shafts before removing the caliper mounting bolts

3. Remove the pads from the caliper. Unscrew the two allen head shafts evenly, and then remove the inside caliper half and the caliper mounting bracket, pulling them straight off. Pull the allen head shafts from the outside caliper, being careful not to damage the shafts or the O-rings.

Unscrew the shafts evenly.

4. Remove the band and the dust seal from the piston in the outside caliper half.

5. The piston can be removed from the outside caliper half by blowing compressed air into the brake line inlet. If compressed air is not available, reconnect the brake line and pump the brake lever to force the piston out.



NOTE: *These are the only recommended methods for removing the piston.*

6. Remove the piston ring from the cylinder.

Inspection

NOTE: *Caliper components should be kept free of any solvent. Parts should be cleaned only in brake fluid.*

1. Inspect the piston for scoring along the sides or for other signs of wear. Replace as necessary.

Two-piece caliper assembly

1. Dust seal	10. Lockwasher	19. Caliper A (outer)
2. Caliper mounting	11. Caliper B (inner)	20. Disc
3. Bleeder valve cap	12. Ring	21. Lockwasher
4. Bleeder valve	13. Pad B (inner)	22. Bolt
5. Bushing	14. Pad A (outer)	23. Bolt
6. Stopper	15. Dust seal	24. Lockwasher
7. O-ring	16. Band	25. Washer
8. Shaft	17. Piston	
9. Screw	18. Ring	

2. Replace any damaged seals in the unit. All seals should be replaced every two years regardless of appearance.

3. Refer to the chart at the end of this section for specifications.

Assembly and Installation

1. Clean the components in brake fluid, be sure to clean the ring groove inside the cylinder.

2. Lubricate the piston ring and piston with fresh brake fluid, and insert them into the cylinder in that order. Push the piston in as far as possible.

Removing the dust seal

3. Install the dust seal and band onto the piston. These parts should be kept free of oil or brake fluid.

Joining the caliper half and mounting bracket

4. Install two O-rings on each of the allen head shafts. Coat the area between the O-rings with PBC (PolyButyl-Cuprysil) grease before inserting the shafts into the outside caliper (caliper A).

5. Install two dust seals in the caliper mounting, and slide the mounting over the shafts. The dust seals should fit around the outside of the mounting as shown.

6. Install the other set of dust seals onto the shafts, then install the inside caliper while screwing the allen head shafts into it evenly to a torque of 22–26 ft lbs. Check that the caliper moves smoothly on the shafts. Install the pads.

7. Mount the caliper on the fork slider, torque the mounting bolts to 18–24 ft lbs, then connect the brake line. Bleed the brake system as previously described.

ONE-PIECE CALIPER

Removal

1. Remove the front wheel.

2. If the caliper is to be disassembled, remove the two caliper holder shaft nuts on the wheel side of the caliper.

Loosen the caliper holder shaft nuts before removing the caliper mounting bolts

3. Disconnect the brake line from the caliper and cap the end with the bleeder valve cap to prevent fluid loss.

4. Remove the two caliper mounting bolts and take off the caliper.

Disassembly

1. Remove the screw, metal plate, and inner pad.

2. Remove the caliper holder shaft nuts which were loosened previously and take out the shafts carefully and equally to avoid damaging the dust covers.

3. Remove the caliper holder and the pad.

4. Remove the piston dust seal.

5. Block the caliper opening with a clean, heavy cloth. Apply compressed air to the brake line fitting to push out the piston. If not available, reconnect the brake line to the caliper and apply the brake lever to push out the piston. Be prepared for spilled fluid.

6. Remove the fluid seal with a hooked tool, taking care that the caliper bore is not damaged.

Inspection

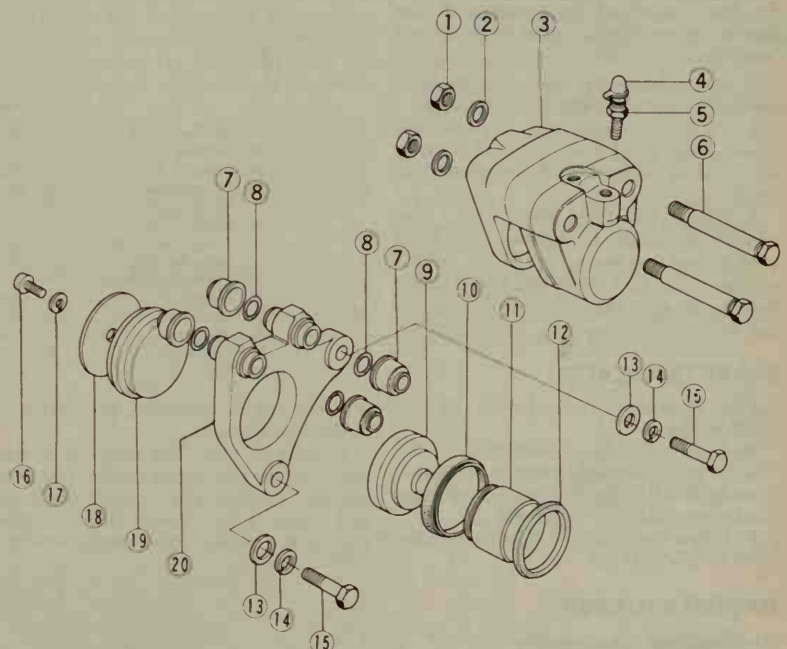
1. Clean caliper components in clean brake fluid only. Do not use solvents.

2. Check the piston for scuffing or imperfections and replace it if damaged.

3. Replace the piston seal as a matter of preventive maintenance, and dust covers and o-rings if damaged.

4. Refer to the chart at the end of this section for caliper specifications.

Assembly



1. Fit the fluid seal into the caliper.

2. Lubricate the outsides of the piston with clean brake fluid and push it carefully into the caliper by hand as far as possible.

3. Fit the dust seal into its groove.

4. Apply a light coat of high-temperature waterproof grease (PBC) to the holder holes and caliper holder shafts. With the dust covers and o-rings and caliper holder in place, carefully insert the shafts, turning them as they are inserted.

5. Fit the spacers to the shafts, pro-

18. Metal plate
19. Pad B
20. Caliper holder

Assembling the caliper components

truding side facing the caliper. Screw on the nuts, tightening them to the proper torque after installing the caliper on the fork slider.

6. Install the pads as outlined in "Pad Replacement" preceeding.

Installation

1. Tighten the caliper mounting bolts to 25–33 ft lbs.
2. Tighten the caliper holder shaft nuts to 17.5–20 ft lbs.
3. Connect the brake line to the caliper and tighten the fitting to 12–13 ft lbs.
4. Check fluid level in the master cylinder and bleed the brake.

BRAKE DISC (EARLY)

1. Check the disc for run-out by securing a dial gauge to the fork slider. If run-out is 0.012 in. (0.3 mm) or more, remove the disc and check for warpage. If the disc is not warped, suspect the wheel bearings.

2. Measure the disc thickness. Replace the disc if less than 0.217 in. (5.5 mm).

3. To remove the disc, remove the front wheel, bend down the locking tabs on the disc securing bolts, and remove the bolts.

4. When installing the disc, care should be taken to tighten the bolts evenly and gradually until the proper torque of 12–16 ft lbs is reached. Ensure that the locking tabs are bent up against the flats on the disc bolts.

BRAKE DISC (*LATER*)

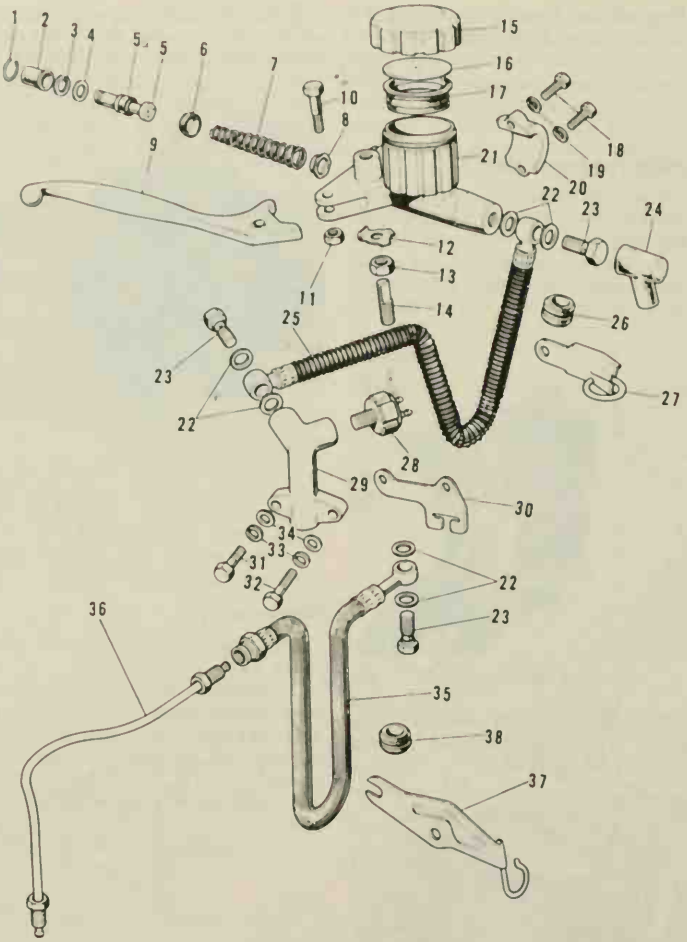
The "later" disc is used with the one-piece caliper.

1. Inspect the disc as outlined for the "Early" type above. Maximum allowable run-out is 0.012 in. (0.3 mm). Minimum thickness is 0.24 in. (6.0 mm).

2. When installing the disc, tighten the bolts to 25–33 ft lbs.

MASTER CYLINDER

Removal and Disassembly



1. Disconnect the brake fluid line from the master cylinder.

2. Remove the two mounting bolts and the master cylinder assembly.

3. Remove the reservoir cap, seal, and plate. Drain the brake fluid.

4. Unscrew the mounting bolt and nut, then remove the brake lever.

5. Using a piece of heavy wire bent into a hook at the end, remove the securing ring and the dust seal. Be careful not to damage the seal.

Disc brake master cylinder assembly

1.	Dust seal stopper	14.	Bolt	27.	Bracket
2.	Dust seal	15.	Cap	28.	Pressure switch
3.	Circlip	16.	Plate	29.	3-way fitting
4.	Piston stopper	17.	Cap seal diaphragm	30.	Guide
5.	Piston assembly	18.	Bolt	31.	Bolt
5a.	Secondary cup	19.	Washer	32.	Bolt
6.	Primary cup	20.	Master cylinder mounting	33.	Lockwasher

10.	Bolt	24.	Dust cover	37.	Bracket
11.	Nut	25.	Hose	38.	Grommet
12.	Lockwasher	26.	Grommet		
13.	Nut				

6. Remove the securing snap-ring, then remove the stopper plate, piston assembly, primary cup, spring assembly, and check valve. Leave the secondary cup on the piston unless replacement is necessary. Do not remove the spring seat from the spring.

NOTE: *Do not clamp the master cylinder tightly in a vise, as distortion may result.*

Removing the dust seal and ring from the master cylinder

Inspection

1. Wash all parts in new brake fluid only.
2. Check the master cylinder port for clogging due to foreign matter.
3. Be sure that the reservoir is clean.
4. Check the walls of the master cylinder for grooves or score marks.
5. Check the outlet end for dents or other damage.

In the event of any permanent damage, replace the master cylinder body.

6. Check the piston for wear or rust and replace as necessary.
7. Check the condition of the cylinder cup noting any evidence of grooved

wear on the contact surface. Replace if any is evident.

8. Check all rubber parts for wear, damage, or swelling. Replace as necessary. Note that all rubber parts should be replaced every two years regardless of appearance.

9. Check the reservoir diaphragm for cracks or damage to the edges and the accordion pleats. Check the diaphragm for swelling.

These components should be replaced if damaged or worn, and replaced every two years regardless of appearance.

10. The master cylinder spring minimum length is 1.9 in. (48 mm). Replace it if it is shorter than this or if it shows signs of damage.

11. Check the brake hose and line for cracks or seepage. The brake hose should be replaced every four years regardless of condition.

12. When installing the hose and line, note that they should not contact the forks or frame at any point except where attachment clips are fitted.

Assembly and Installation

1. Thoroughly lubricate the piston assembly, primary cup, and check valve with brake fluid prior to assembly.

2. Insert the primary cup and piston assembly into the master cylinder in that order.

NOTE: *Make sure that the primary cup and check valve do not turn sideways during installation.*

3. Install the stopper, then fit the snap-ring in its groove. Replace the snap-ring if it does not rotate smoothly in its groove.

4. Install the dust seal and seal stopper. Make absolutely certain that the seal seats properly in the piston groove.

5. Install the brake lever.

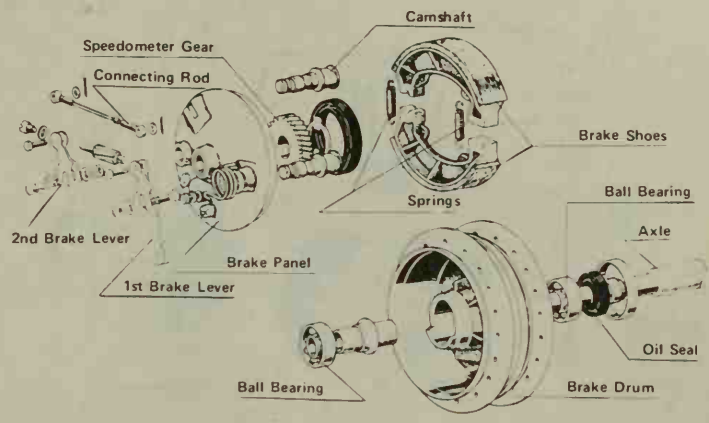
6. Hold the cylinder and squeeze the lever to make certain that it operates smoothly. Put a finger over the hose connection: you should be able to detect suction when the lever is released.

7. Fill the reservoir with brake fluid and install the cap.

8. Squeeze and release the lever several times until the fluid is pumped out the hose connection. Do not squeeze the lever to the limit of its travel or damage to the secondary cup may result.

9. Squeeze the lever, cover the hose connection with a finger, then release the lever: it should return to its original position quickly and smoothly.

10. Mount the assembly on the handlebar, and tighten the top mounting bolts first.



11. Adjust the brake lever to have less than 3/16 in. free-play.

12. Connect the brake hose, fill the reservoir, and bleed the system as previously described.

Wheel Bearings

REMOVAL

Removal of the wheel bearings necessitates removing the hub oil seals. These must be replaced with new ones upon reassembly. Clean the outside of the hub before removing the wheel bearings.

Front drum brake assembly

1. Remove the wheel and take out the brake plate. On disc brake models, unscrew the axle, and remove the speedometer drive mechanism.

2. Remove any dust covers, dust seals, or axle spacers fitted to either side of the hub.

3. Pry out the oil seals on either side of the hub using a small screwdriver, or, preferably, an elbow-shaped tool.

4. Remove the bearing retainer snap-ring (if fitted).

5. Remove the first bearing by tapping the bearing spacer tube; the spacer tube can be removed with the first bearing. To remove the remaining bearing, reach through the hub with a drift and tap the bearing evenly around its circumference. When removing the bearing, keep the bearing surface at a 90° angle to its seat in the hub.

NOTE: *On some models, especially high mileage machines, the hub should be heated gently with a propane torch in the vicinity of the bearing bosses to facilitate removal.*

INSPECTION

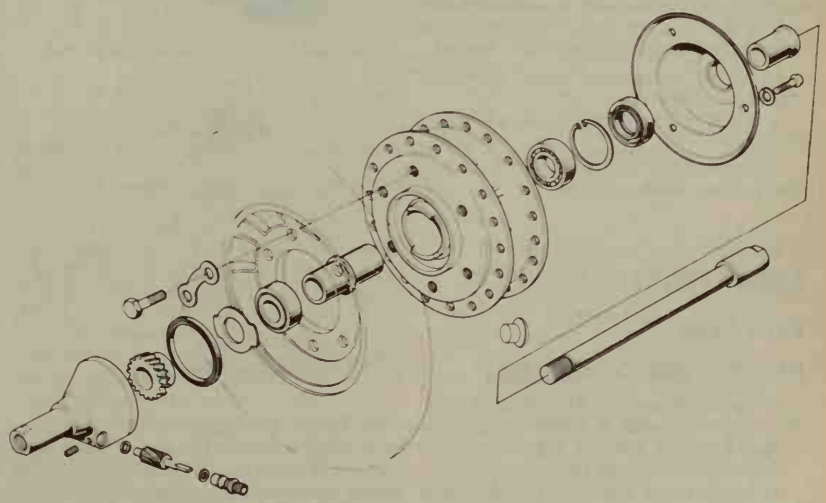
NOTE: *The following bearing inspection checks refer to the sprocket hub bearing as well as the wheel bearings.*

1. Clean the bearings and spacer tube in a suitable solvent, removing all of the old grease. At this point, it would be wise to clean out the hub as well.

2. Check the bearing bosses in the hub for scuffs, cracks, or distortion. If they are in any way damaged, the hub must be replaced.

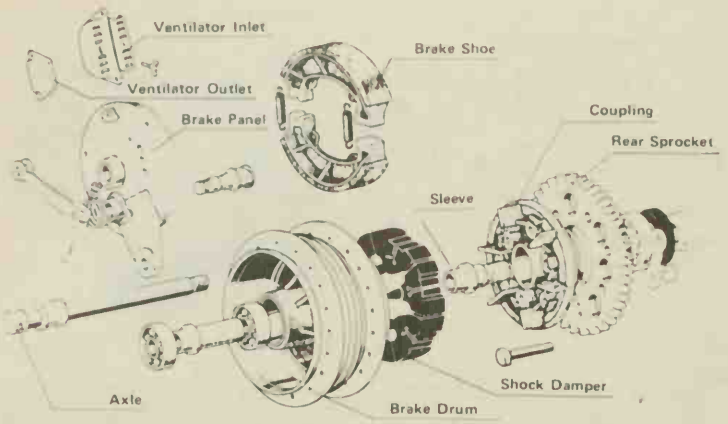
3. Check the condition of the spacer tube and replace if damaged.

4. Apply a few drops of light oil to the bearing, and spin it. The bearing must rotate smoothly and freely. Any roughness or binding in rotation will necessitate a new bearing.



5. Place the bearing on a flat surface. Place your fingers on the outer bearing race to hold it steady. Try to move the inner race back and forth. In a good bearing, it will not be possible to move the inner race. If it is, the bearing must be replaced.

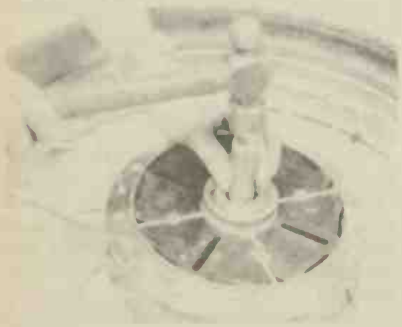
6. Note that bearings must be replaced in pairs.



ASSEMBLY

1. Obtain a good grade of wheel bearing grease to lubricate the wheel bearings.

2. Pack the grease in the bearing. A common method of doing this is to place a goodly amount of the grease in the palm of one hand. Taking the clean, dry, bear-



Front disc brake assembly

Rear brake assembly (H1)

ing, press one section of it into the grease. Turn the bearing until the grease has been deposited around the entire circumference. The packing process is complete when the grease begins to come out of the upper side of the bearing. Place an amount of grease in the hub as well.

Installing a wheel bearing

3. Heat either side of the wheel hub with a propane torch as on removal of the bearings. Place one of the bearings in the hub, and make sure that it is seated.

Any bearing to which a retainer is fitted should be installed first. On most machines the axle can be used as a drift to install the first bearing. Insert the axle into the bearing until the larger diameter end rests on the bearing. Center the bearing in the bearing boss, then strike the axle sharply until the bearing is seated.

4. Fit the spacer, and install the other wheel bearing.

5. Press in new oil seals on both sides of the hub.

6. Tighten the axle to 51–80 ft lbs. on disc brake wheels.

FRONT FORKS

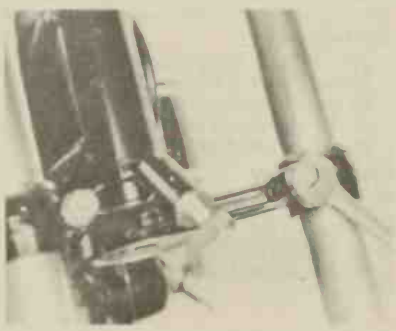
Early Type

REMOVAL AND DISASSEMBLY

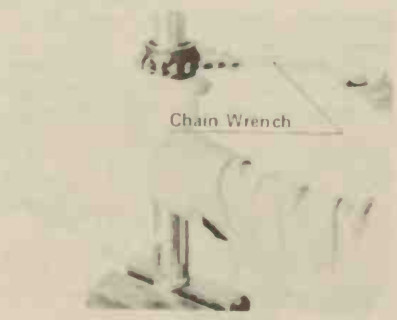
1. Remove the front wheel and fender.

2. If a disc brake is fitted, remove the caliper from the left fork leg.

3. Remove the fork filler caps.



4. Loosen the upper (if fitted) and lower triple clamp pinch-bolts.



Removing the fork filler caps

5. Withdraw the fork legs one at a time from the steering stem.

6. Remove the spring from the top of the fork tube and invert the fork leg over a suitable container to pour out the oil.

Loosening the lower triple clamp pinch bolts

Removing the slider nut

7. Clamp the bottom of the fork slider in a wood jaw vise, lift up the slider dust seal, and unscrew the slider nut with a chain wrench or pipe wrench.

NOTE: *If neither of these tools are available, wrap the slider nut with a piece of old inner tube and tighten a heater hose clamp around the inner tube. With the clamp tightened securely, grasp the screw fitting with a pair of vise-grips and unscrew the nut.*

8. Grasp the fork tube with one hand and the slider with the other and pull them apart.

9. Remove the oil seal from the slider nut.

INSPECTION

1. Measure the free-length of the fork spring. Replace both if either is found to be less than the service limit given in the "Chassis Specifications" chart at the end of this section.

2. Install the fork tube and sliding bushing into the slider. Check that the tube slides smoothly, with a minimum of play.

3. Check the inside bore of the sliding bushing for score marks. Replace if scored.

4. Install the sliding bushing on the fork tube and check for play, if play is excessive replace the bushing.

5. Install the sliding bushing into the slider, it should be a light press fit. If it is a loose fit in the slider replace the bushing.

6. Check the fork tube for any dents, score marks or bends, replace if defective. The plating must be in good condition.

7. Inspect the slider and the slider nut for broken or stripped threads, and replace as necessary.

8. Inspect the filler cap O-ring and replace it if it is torn, cracked, or nicked.

ASSEMBLY AND INSTALLATION

1. Install a new oil seal into the slider nut and lubricate it before installing it on the fork tube.

2. Install the fork tube and sliding bushing into the slider and screw the slider nut onto the slider securely.

3. Slip the dust seal down over the slider nut.

4. Fill the forks with the correct amount and grade of oil and install the spring holder and the spring.

5. To install the fork legs, slip them up and through the steering stem. Replace the filler caps, and tighten the lower triple clamp pinch-bolts making sure that the top of the fork legs are even with the top of the upper triple clamp.

6. Check that the filler caps are tight and tighten the upper triple clamp pinch-bolts (if fitted). On models with a disc brake, refit the caliper to the left fork leg.

7. Install the front fender and wheel, and check the forks for smooth and proper operation.

Later Type

The late-type forks are used on late model 400–750 machines.

REMOVAL AND DISASSEMBLY

1. Refer to Steps 1–5 under "Early Type" forks for removal procedures.

2. Remove the fork spring and pour out the oil.

3. Remove the dust cover from the top of the fork slider.

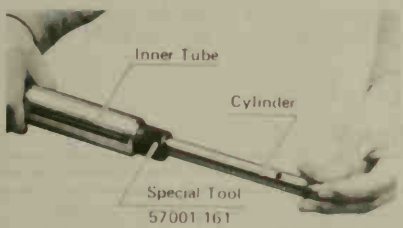
4. Remove the allen bolt from the bottom of the fork slider. The damper cylinder into which the allen bolt is threaded may turn with the bolt making removal impossible. If this happens, it may be possible to free the bolt using an impact driver. Alternately, a special tool is used which is threaded to the top of the cylinder, holding it in place while the allen bolt is removed.

5. After removing the allen bolt, separate the fork slider from the fork tube.

Using the special tool to remove the slider allen bolt

6. Remove the circlip from the bottom of the fork tube to remove the damper components.

7. Remove the slider oil seal circlip and pry out the slider. New seals must be used on assembly.

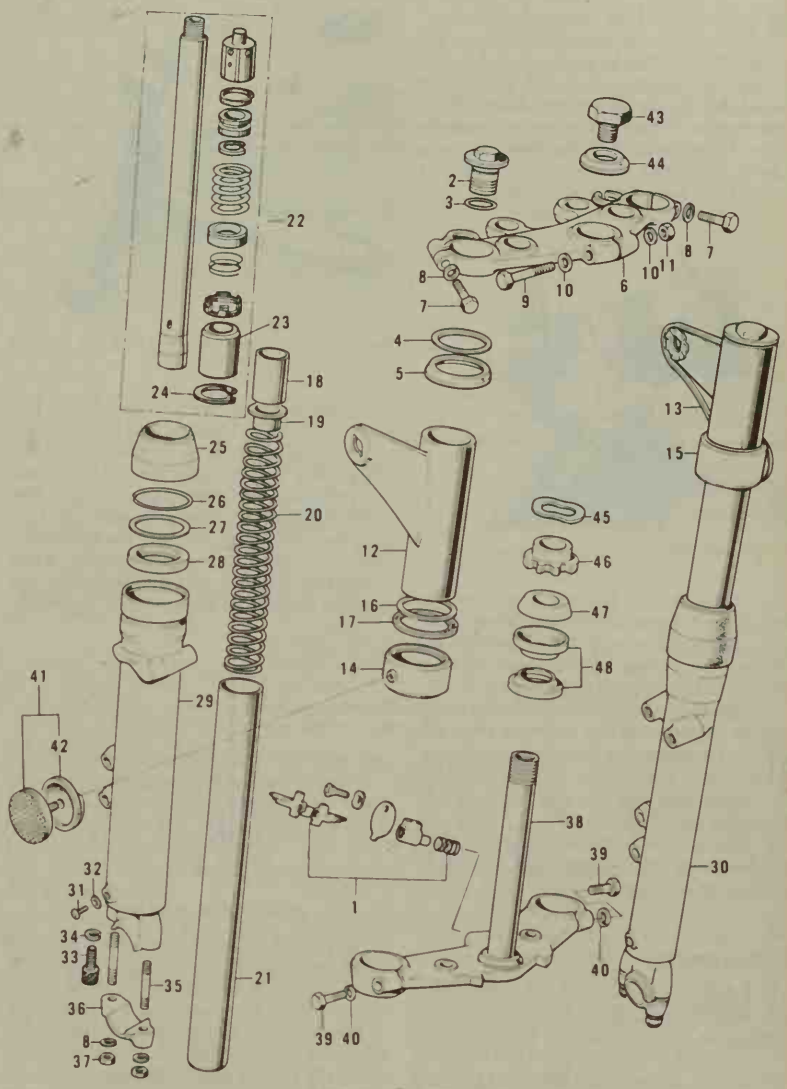


INSPECTION

1. Measure the free length of the fork springs and compare to the serviceable limit given in the "Chassis Specifications" chart.

2. Clean the damper components in a solvent and check for wear, especially of the cylinder ring. Lubricate all components before assembly.

ASSEMBLY AND INSTALLATION



1. Assembly is the reverse of disassembly. A special tool is used to install the cylinder components into the fork leg.

Using the special tool to assemble the late type front fork

2. Press new oil seals into the sliders insuring that they are not tilted and are fully seated. Install the washer and circlip, being sure that it is seated in its groove. Lubricate the seal lips with fork oil before installing the slider on the tube.

3. Refer to Steps 3–7 under "Early Type" forks for remaining operations.

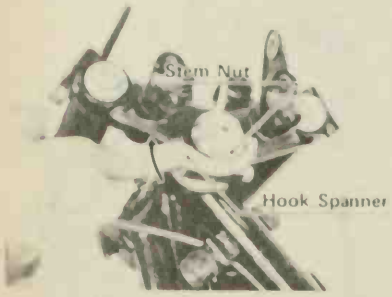
STEERING STEM ASSEMBLY

Bearing Adjustment

On models equipped with a friction steering damper, the damper should be loosened (counterclockwise) as much as possible so that it does not interfere with the bearing movement while checking or adjusting the bearings. If an oil damper is fitted, remove it from the steering stem.

1. The steering stem bearings are uncaged ¼ in. balls. They are adjusted by means of a ring nut beneath the upper triple clamp.



2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender, place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt, at the lower triple clamp, the bearings are adjusted too loosely or worn.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bear-

ings are damaged, or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The forks should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

Adjusting the steering head bearings

6. To adjust the bearings, remove the front wheel, front forks, handlebars, and the upper triple clamp. The bearings are adjusted by means of the stem adjuster nut under the upper triple clamp.

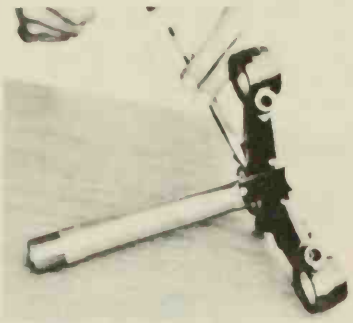
7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above. Temporarily install the forks, upper triple clamp, and the steering stem nut to check the adjustment.

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Disassembly

1. Remove the front wheel, front forks, and handlebars. If a friction steering damper is fitted remove it by removing the cotter pin from under the lower triple clamp, and unscrewing the damper rod and removing the friction plates. If an oil shock is fitted unbolt it from the lower triple clamp.

2. Disconnect the wiring inside the headlight shell, and remove the headlight shell.



3. Unscrew the steering stem nut and disconnect the speedometer and tachometer cables from their instruments. Remove the upper triple clamp.

4. Loosen the steering stem adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race and ball bearings from the top race.

5. Carefully pull the steering stem out from the bottom. Some of the ball bearings from the lower race will probably fall out at this time so be prepared for this.

6. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. These will have to be pried off with a chisel, therefore only remove them if necessary.

CAUTION: *Take care not to damage the steering stem when removing the lower cone race.*

Removing the lower cone race from the steering stem

7. The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

Removing the frame races

New races are installed with a suitable sized bearing driver: i.e., one which will drive the race square into this seat. Be certain that the race goes straight in.

These races can also be installed using a block of hard wood of sufficient size to cover the race in place of a bearing driver.

Inspection

1. Wash the ball bearings in a suitable solvent.

2. Clean all of the old grease from the bearing race surfaces, steering stem, and frame lug.

3. Inspect the bearing race surfaces. They must be clean and smooth. That is free from any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races. Note any roughness or ripples on the race surface. If any imperfections are noted, both the sets of races and all of the balls must be replaced.

4. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

NOTE: *Balls and races must always be replaced in a set as worn races will destroy new balls and worn balls will destroy new races.*

5. Check the dust seal for condition and replace if torn or cracked.

6. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Installation

1. Install the dust seal washer, dust seal, and lower cone race on the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the upper race in the frame lug.

2. Embed 19 balls into the grease in both the bottom cone race and the top race.

3. When the balls are in place, slip the steering stem through the frame lug and hold it in place while refitting the top cone race and threading on the adjuster nut.

4. Tighten the adjuster nut all of the way by hand, rotating the steering stem to work the grease into the balls.

Disc Brake Specifications

Measurement	*Standard (in., mm)*	*Service Limit (in., mm)*
Disc thickness (two-piece caliper) (one-piece caliper)	0.276/7.0 0.27–0.28/6.9–7.1	0.217/5.5 0.24/6.0

General Torque Specifications

Coarse Threads

Diameter (mm)	Torque (ft lbs)
5	2.5–3.5
6	4.6–6.4
8	11.6–15.9
10	22.4–30.4
12	39.1–54.2
14	60.0–83.2
16	94.0–130
18	130–181
20	188–253

Fine Threads

Diameter (mm)	Torque (ft lbs)
5	2.5–3.5
6	4.0–5.6
8	9.8–13.4
10	18.4–25.3
12	32.5–44.8
14	53.5–73.8
16	83.2–116
18	123–166
20	166–239

5. Tighten the adjuster nut until the steering stem turns freely, but has no play.

6. Install the fork tubes, headlight assembly, and upper triple clamp, flat washer, and steering stem nut. Check that the stem moves freely of its own weight when released from 5°–10° off center.

7. Install the front fender, front wheel, and handlebars.

SWING ARM

All Models

INSPECTION

1. Disconnect the chain. Remove the rear wheel and sprocket assembly.

2. Remove the shock absorbers and chain guard.

3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced or fixed.

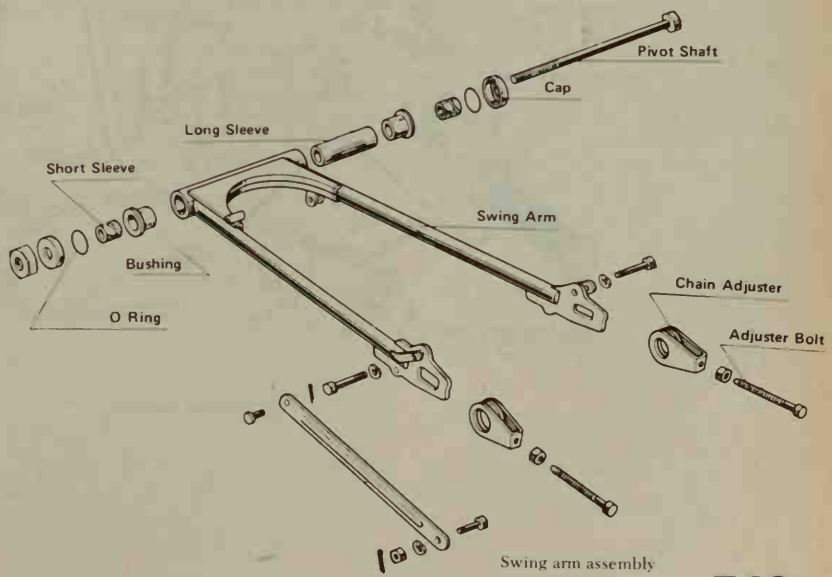
4. Check that the rear wheel mounting plates are parallel.

5. Grasp the legs of the swing arm and attempt to move it from side-to-side. Any noticeable side-play will indicate that the swing arm bushings in the frame need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

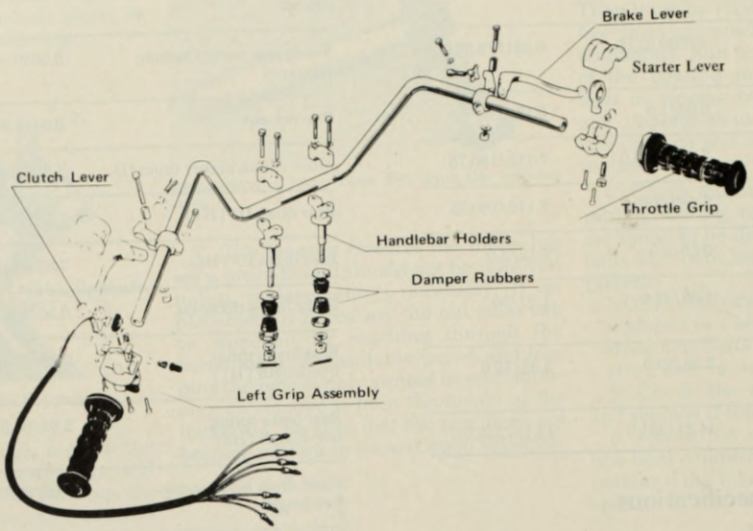
REMOVAL

1. Proceed as above. Then remove the swing arm pivot shaft nut, and pull out the pivot shaft.



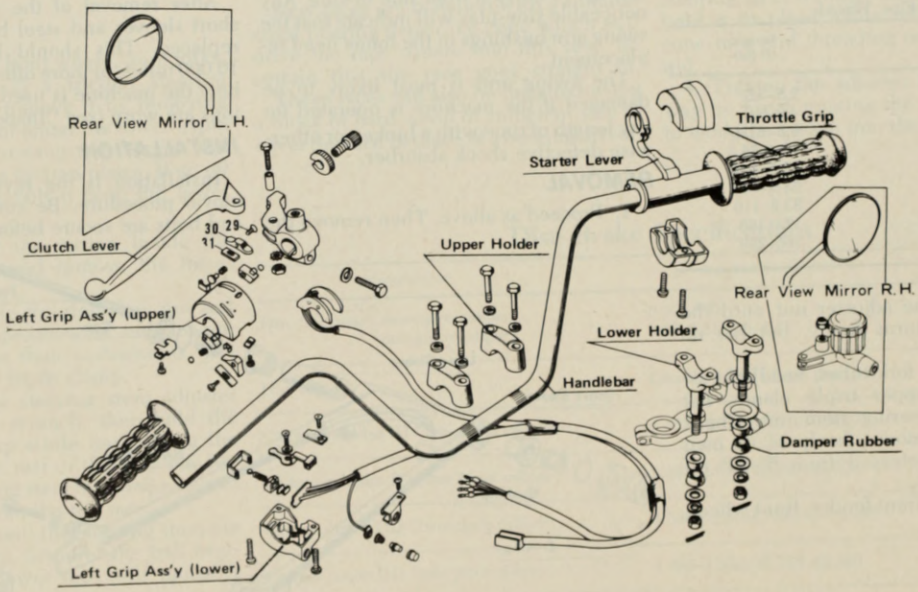
2. Remove the swing arm. Note the dust caps and O-rings on either side of the swing arm.

3. The swing arm should be inspected for cracks or fractures, especially around the welds.



After removal of the swing arm, the short sleeves and steel bushings can be replaced. This should be done every 10,000 miles, or more often depending on how the machine is used, or if the bushings are worn (see "Inspection," above).

INSTALLATION



Installation is the reverse of the removal procedure. Be sure that all nuts and bolts are secure before operation.

Swing arm assembly

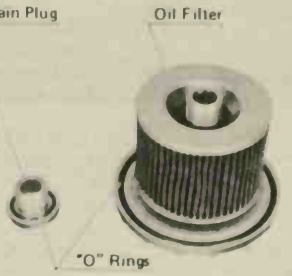
LUBRICATION

Checking Oil Level

1. A dipstick is fitted to the filler cap on top of the crankcase to check the oil level. To get an accurate level reading, the engine must be warm, and the machine must be parked on the center stand on a level surface.
2. The dipstick should be fully screwed into its threads when checking the oil level.
3. Maintain the level between the marks.



Changing Oil

1. The oil change interval is 1,800 miles. SAE 10W–40, 10W–50, or 20W–50 service rating "SD" or "SE" is recommended.
2. Change oil when the engine is at operating temperature. The machine should be parked on the center stand and on a level surface to ensure full drainage of the oil.
3. Remove the filler cap. Remove the drain plug from the bottom of the crankcase and allow the oil to drain.
4. Clean off the plug (it is magnetic to trap metal particles). Check the condition of the O-ring. Refit, tightening the plug to 14.5–18 ft lbs.
5. If the filter is to be changed, refer to the following section.
6. Add the correct grade and quantity of oil. If the filter has been changed, add 3.0 1/3.2 qt. If the filter has not been changed, add 2.6 1/2.8 qt.
7. Allow the engine to idle for a few minutes, then check the oil level and top up if necessary.

Oil Filter

1. A cartridge-type oil filter is fitted to the bottom of the crankcases. The filter should be changed at every other oil change or at intervals of about 3,600 miles.
2. Drain the oil as described above. Unscrew and remove the oil filter.
3. Install the new filter element ensuring that the O-rings are in good condition and properly fitted. Tighten the filter to 11–14.5 ft lbs.
4. Add 3.0 1/3.2 qts of oil to the engine, then check oil level as described above.

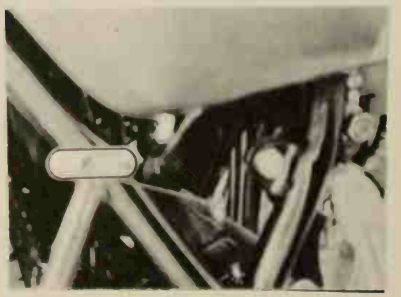
Oil filter and drain plug O-rings

FRONT FORKS

Checking Oil

1. Front fork oil level should be checked about every 3,600 miles.
2. Support the front wheel off the ground.
3. Remove the filler cap from the top of each fork and insert a suitable rod into the fork to check the level. Oil level should be 340–360 mm (13.4–14.1 in.) from the top of the fork tube.

Checking fork oil level



4. Add a quantity of the type of fork oil in use, if necessary, to bring the level up to the proper specification.

Changing Oil

1. Fork oil should be changed about every 6,200 miles.
2. SAE 5W–20 oil is recommended. Fork capacity is 150–170 cc (5.1–5.8 oz) for each leg.
3. Remove the drain bolt from the bottom of one slider. Apply the front brake and push forward on the handlebars with the machine off its stand to pump out the oil. Repeat with the other fork leg.
4. After fitting the drain bolts, and with the machine on the center stand and the front wheel supported off the ground, remove the filler caps from the top of each fork leg and add the correct grade and quantity of oil.
5. Check the condition of the filler cap O-rings, then refit and tighten them to 18–22 ft lbs.

CHASSIS LUBRICATION

1. The swing arm is fitted with a

Swing arm grease fitting

grease nipple and should be lubricated with a high-quality chassis grease about every 1,800 miles. Apply grease until some appears at either end of the swing arm.

2. At the same intervals, lightly oil brake lever fittings and carburetor linkage. Lubricate controls and cables.

3. Lubrication of the wheel bearings, brake cams, speedometer gear housing, and steering stem bearings is required every 2 years or about 12,000 miles. Use a high-quality bearing grease for these operations.

Refer to "Chassis" for procedures.

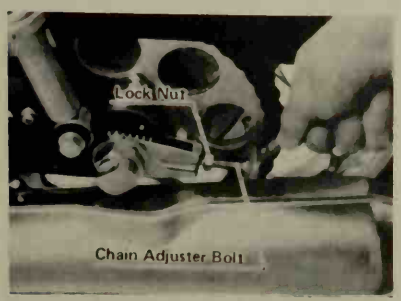
SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have 20–25 mm (¾–1 in.) of total up and down movement. This is measured in the middle of the lower chain run and at the tightest point of the chain, if such a tight spot exists.

2. When checking chain slack, the machine should be parked on the center stand, and the chain must be clean and well-lubricated.

3. If adjustment is necessary, remove the safety clip and loosen the brake anchor nut on the brake plate. Loosen the axle nut after removing the cotter pin.



Loosening the coupling sleeve nut

4. Loosen the coupling sleeve nut.

5. Loosen the adjuster bolt locknuts. Turn the adjuster bolts in or out until the proper chain slack is attained. Be sure that the index notch on the adjusters align with the same swing arm reference mark on both sides.

6. Tighten the adjuster bolt locknuts, the coupling sleeve nut, and the axle nut. Recheck chain slack. If correct, fully tighten the axle nut to 95–116 ft lbs.

Adjusting the chain

Tighten the brake anchor nut to 20–22 ft lbs. The use of new cotter pins is recommended.

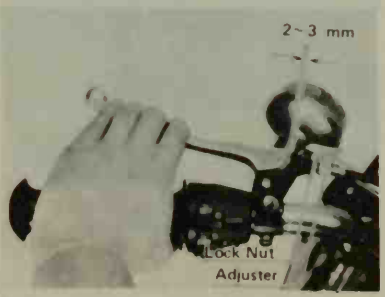
7. Check rear brake and brake light switch adjustments.

8. Periodically (1,800 miles) the chain should be checked for wear. Refer to "Chassis."

Clutch

1. Using the adjuster at the handlebar, maintain clutch cable free-play so that when the clutch lever is pulled, there is a gap of 2–3 mm (0.08-0.12 in.) between the lever and the lever bracket before the clutch begins to disengage.

Adjusting the clutch



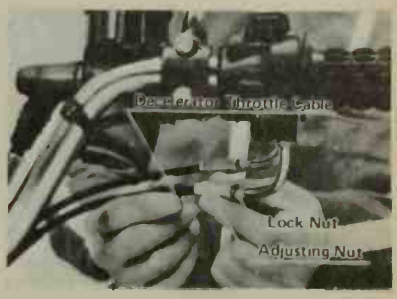
If clutch operation is not satisfactory in spite of the above adjustment, or if new plates have been fitted, proceed as follows:

2. Slide back the dust cover from the cable adjuster located about halfway along the cable. Screw the adjuster in to put as much slack in the cable as possible.

3. Loosen the locknut at the handlebar cable adjuster and turn the adjuster so that there is a gap of 5–6 mm (0.20–0.24 in.) between the adjuster and the locknut.

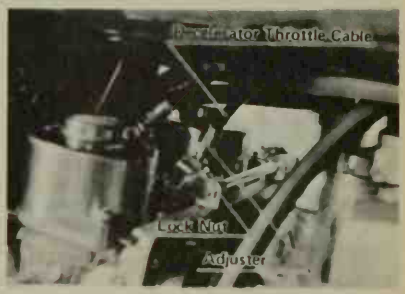
4. Remove the clutch adjusting cover. Loosen the locknut and back the adjusting screw out 3–4 turns.

5. Turn the screw in until resistance is felt, then back it out ½ turn and tighten the locknut.



Proper clutch cable free-play

6. Take up all of the cable slack with the main cable adjuster. Refit the adjuster dust cover.



7. Use the handlebar adjuster to give the correct amount of clutch cable free-play as in Step 1.

Throttle Cables

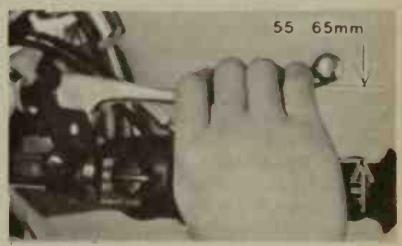
1. Loosen the locknuts for the throttle cable adjusting nuts at the twist-grip, and screw both adjusting nuts in to yield as much cable free-play as possible.

Turning the decelerator adjusting nut out

Decelerator cable adjuster at the carburetor

2. Turn the adjusting nut for the decelerator cable out three turns. If this takes up all the play at the twist-grip, loosen the decelerator adjuster locknut (at the carburetors), and turn the adjuster to yield a small amount of free-play, then tighten the locknut.

3. Turn the accelerator cable adjusting nut at the twist-grip out until twist-grip play is almost gone, then tighten the locknut.

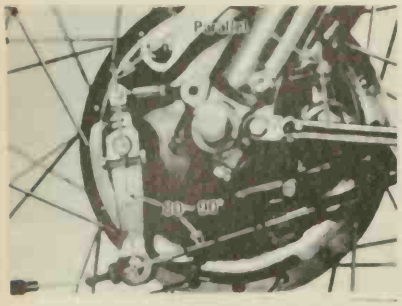


4. Turn the decelerator adjusting nut in until the desired amount of twist-grip free-play is obtained, which should generally be about 10–15° of grip rotation.

5. Check the tightness of all locknuts. Check throttle operation before riding the motorcycle.

Front Drum Brake

1. Use the lower cable adjusting nut to maintain the proper adjustment. When the brake is fully applied, there should be 55–65 mm (2.2–2.6 in.) between the brake lever and the twist-grip.



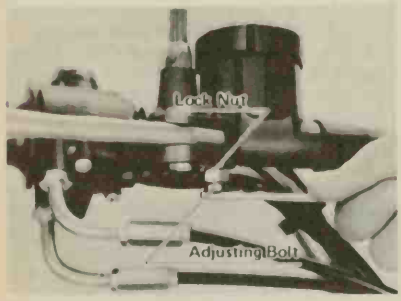
2. Make minor adjustments using the adjuster at the handlebar.

Proper front drum brake lever free-play

3. Check brake wear by means of the wear indicators fitted to the brake plate. The indicators must stay within the "Usable Range" when the brake is fully applied, or linings must be replaced.

4. When the brake is fully applied, the angle formed by the cable and the main brake lever at the brake plate must be

An angle in excess of 80–90° will result in reduced brake effectiveness



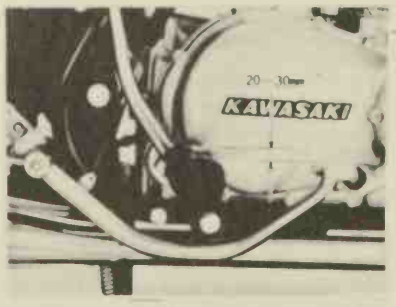
within 80–90°. If the angle exceeds this amount, brake effectiveness will be reduced. Further, the main and secondary brake levers should be parallel. This adjustment can be made with the threaded connecting rod, but is usually not necessary unless the brake plate has been disassembled, or new shoes have been fitted. Refer to "Chassis" for this procedure.

Front Disc Brake

1. Check pad wear. When either pad is worn down to the stepped portion, replace both as a set.

2. Check fluid level. A level line is inscribed on the inside of the master cylinder reservoir. The fluid level may drop very slightly as the pads wear. Before adding fluid, refer to the "Chassis" section which provides proper procedures for disc brake work.

The brake fluid should be changed each year or every 6,200 miles, whichever comes first. Refer to "Chassis" for procedures.



Disc brake lever adjuster

3. Check brake lever play. The tip of the lever should not move more than 5 mm (0.10 in.) before the brake is applied. If adjustment is necessary, an adjusting bolt is fitted to the underside of the lever bracket. Bend down the tab on the lockwasher, loosen the locknut while holding the adjusting bolt steady, then turn the bolt very slightly so that lever travel is corrected.

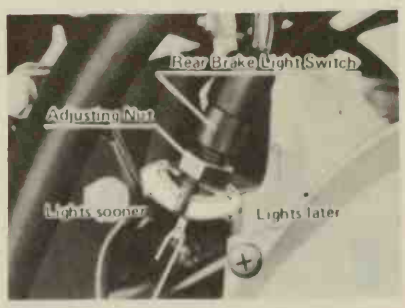
4. Tighten the locknut to 13–16.5 ft lbs. Bend down the lockwasher tab.

Rear Brake

1. The brake pedal is adjustable for position. It should be set so that the knurled surface of the pedal is 20–30 mm (0.8–1.2 in.) below the top of the footpeg rubber.

Brake pedal free-play

2. If adjustment is necessary, back off the brake adjusting nut. Loosen the locknut on the pedal height adjustment bolt, and turn the bolt so that pedal height is correct. Tighten the locknut. Adjust the rear brake.



3. The brake is correctly adjusted if the pedal is free to move 20–30 mm (0.8–1.2 in.) before the linings contact the drum. Adjustment is made with an adjusting nut on the end of the brake rod.

4. When the brake is fully applied, the wear indicator must be within the "Usable Range" or the lining will have to be replaced. Further, the angle formed by the brake lever and rod when the brake is applied should be about 80–90°. If the angle exceeds this amount, braking effectiveness will be reduced. It is possible to remove the lever from the brake cam and reposition it so that the proper angle is not exceeded when the brake is applied.

5. After adjusting the brake, check the operation of the brake and the adjustment of the brake light switch.

Brake Light Switch

1. The front brake light switch for disc brakes is not adjustable. The front drum brake light switch does not need routine adjustment.

2. The rear brake light switch is fitted to a slotted bracket and secured by a locknut. The brake light should go on after about 15 mm (0.6 in.) of pedal travel, or shortly before the linings contact the drum. Make the adjustment by loosening the locknut and moving the switch up or down as necessary. Moving the switch up will allow the light to go on sooner and vice versa.

CAUTION: *Do not turn the switch body itself during adjustment or the electrical connections may be damaged.*

Headlight Adjustment

1. Set the machine about 25 feet away from and perpendicular to a wall, preferably of a color which reflects light well. The machine should be off the stand, and with a rider putting his weight on the machine as in operation.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

3. Vertical adjustment is made by loosening the two headlight shell mounting bolts slightly and pivoting the shell up or down.

4. Lateral adjustment is accomplished by means of the screw on the right-side of the headlight.

Steering Stem Bearings

1. The bearing adjustment should be checked about every 3,600 miles. Refer to "Chassis" for inspection and adjustment procedures.

FUEL SYSTEM

1. Fuel system maintenance involves cleaning the petcock filter, cleaning or replacing the air cleaner, and cleaning the carburetors.

This should be done about every 1,800 miles.

2. Shut off the fuel, and place a funnel or a channel-shaped piece of cardboard or heavy paper beneath one of the carbs. Remove the float bowl drain plug and allow the fuel to drain into a suitable container. Repeat with the other carb. Refit the drain plugs. Check for leaks before operating the machine.

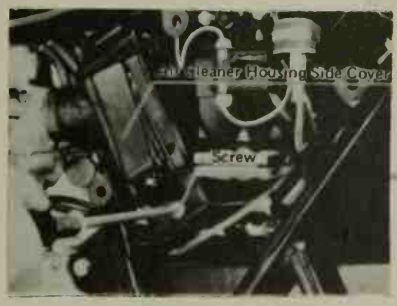
At more frequent intervals, the carburetors should be removed, disassembled, and cleaned. Refer to "Fuel System" for procedures.

3. Be sure that the fuel petcock is "Off." Unscrew and remove the sediment cup. Reach into the petcock body and pull out the O-ring and filter screen strainer. Clean in solvent. If the screen is punctured, replace it.

4. Place a container beneath the petcock and turn it to the "Reserve" position which will serve to remove any water which may have accumulated in the bottom of the gas tank.

5. Check the condition of the O-ring, and replace it if damaged. Install the strainer, O-ring, and sediment cup, and tighten it securely. Check for leaks before operation.

Air Cleaner Service



REMOVAL

1. Remove the left sidecover.

2. Remove the air cleaner housing sidecover screw at the lower portion of the sidecover, and remove the element.

SERVICE

1. Clean the element by washing it in a non-oily solvent. Dry it by applying compressed air from the inside of the element.

Removing the air cleaner

NOTE: *Do not use solvents with dangerously low flash points, or those which may leave an oily residue (such as kerosene).*

2. Check the condition of the element and replace it if torn or punctured.

3. The maximum service life of the element is about 6,000 miles or 5 cleanings, whichever comes first. After this, a new element should be fitted.

INSTALLATION

1. Installation is the reverse of removal. Install the element so that the element holes match the air cleaner ducts.

Maintenance Data

Fuel tank (l/gal)	14/3.70
Engine (l/qt)	
when changing oil only	2.6/2.8
when changing oil and filter	3.0/3.2
Front forks (cc/oz)	150–170/5.1–5.8
Tire pressure (psi)	
Normal	
Front/Rear	25/28
High-speed	
Front/Rear	28–31/31–34
Tire tread depth (mm/in.)

Rating (amp/hrs)	400D—12ah/400S—6ah
Continuous charging rate (amps)	400D—1.2/400S—0.6

① May vary according to local regulations. The manufacturer's standard is given.

Periodic Maintenance Intervals①

Daily
- Brake adjustment
- Engine oil level
- Cable adjustments
- Chain slack
- Lights and safety equipment

Weekly
- Battery electrolyte level
- Spokes for tightness
- Tire pressure (cold)

Every 150 Miles
- Lubricate drive chain

Every 1800 Miles
- Change engine oil
- Grease swing arm
- Lubricate controls and cables
- Check chain wear
- Adust carburetors
- Clean fuel system
- Clean and gap spark plugs
- Adjust cam chain
- Check points and ignition timing
- Clean air filter

Every 3600 Miles
- Replace oil filter
- Checking steering head bearings
- Adust valves
- Check brake wear
- Check fork oil level

Every 6200 Miles
- Replace air cleaner element
- Change fork oil
- Flush and renew brake fluid

Every 12,000 Miles or 2 Years
- Repack wheel bearings
- Repack steering stem bearings
- Lubricate brake cams
- Lubricate speedometer gear housing

① Based upon normal usage after break-in is complete

Recommended Lubricants

Engine
- SAE 10W-40, service rating "SD" or "SE"
- SAE 10W-50, service rating "SD" or "SE"
- SAE 20W-50, service rating "SD" or "SE"

Forks
- SAE 5W-20

Control Cables
- Motor oil
- Graphite-base lubricant
- Molybdenum disulphide-base lubricant

Tach, Speedometer Cables
- Light-duty grease

Wheel Bearings, Steering Stem Bearings
- Waterproof, medium-weight bearing grease

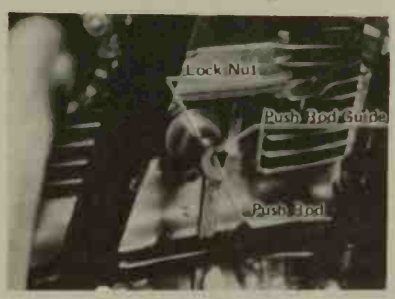
Grease Fittings
- Waterproof, medium-weight chassis grease

Tune-Up

NOTE: *Common tune-up procedures are explained in detail in "General Information"*

IMPORTANT: *In all relevant procedures, note that the normal direction of rotation of this engine's crankshaft is counterclockwise when viewed from the right-side.*

CAM CHAIN ADJUSTMENT



1. The cam chain adjuster is located between the cylinders at the front of the engine.

2. Remove the breaker point cover from the right-side of the engine. Remove the cam chain tensioner cap and O-ring.

3. Remove the spark plugs.

4. Turn the engine over using a 17 mm wrench on the crankshaft *nut* at the points compartment. Turn the crankshaft counterclockwise while observing the tensioner pushrod which is in the center of the pushrod guide.

5. Continue turning the engine over until the pushrod reaches the innermost point, then stop.

Adjusting the cam chain

NOTE: *Hold the crankshaft in place. Do not turn the engine backward.*

6. The end of the pushrod should be flush with the pushrod guide if adjustment is correct. If adjustment is necessary, loosen the large locknut on the tensioner, and turn the guide until the guide and pushrod are flush.

CAUTION: *If the pushrod protrudes even a small bit from the guide, the adjustment is too tight and damage may result.*

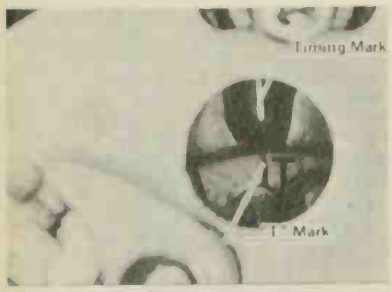
7. Tighten the locknut. Refit the tensioner O-ring and cap. Replace the point cover and spark plugs.

VALVE ADJUSTMENT

NOTE: *Valves must be adjusted when the engine is cold.*

1. Remove the contact breaker point cover from the right-side of the engine.

2. Remove the spark plugs.



3. Remove the cylinder head cover caps from each side of the head. Remove the four valve clearance adjuster plugs.

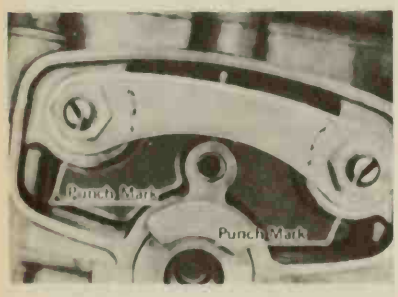
4. Correct clearance for all valves is 0.10 mm (0.004 in.).

5. Using a 17 mm wrench on the crankshaft nut at the points compartment, turn the engine over counterclockwise until the intake valve for the right cylinder opens and begins to close.

6. Continue turning the engine over in the same direction while observing the timing marks through the hole in the breaker plate. About ¼ of a turn after the intake valve closes, the "T" mark will appear. Align the "T" mark with the stationary timing mark, as illustrated.

7. The right-side piston has now been positioned at top dead center (TDC) on its compression stroke. Both valves for the right cylinder should be closed.

Align the "T" mark for valve adjustment



Checking valve adjustment

8. Check the valve clearance by inserting the proper-sized feeler gauge between the valve stem and the rocker arm.

9. If adjustment is necessary, loosen the rocker arm shaft locknut, and turn the shaft carefully in either direction to increase or decrease the clearance as necessary. Refer to the illustration. Do not turn the shaft more than 180°. The punch mark on the shaft must continue to face inward toward the "+" and "−" marks.

To increase valve clearance, turn the shaft toward the "+" mark; to decrease it, turn it toward the "−" mark.

10. Hold the shaft in position, while tightening the locknut to 18–22 ft lbs. After tightening, recheck clearance.

Turn the rocker arm shafts as shown to increase or decrease clearance

11. Repeat the procedure for the other right cylinder valve.

12. Turn the crankshaft 360° (one full turn) until the "T" mark again aligns. The left piston is now at TDC on its compression stroke and the left cylinder valves can now be adjusted.

CONTACT BREAKER POINTS

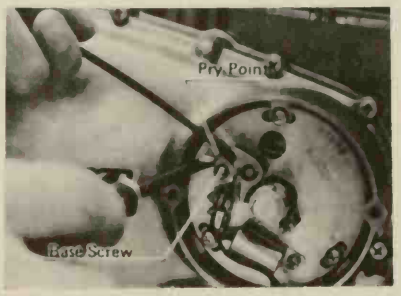
Location

1. The points are located beneath a cover on the right-side of the engine.

2. A single set of points is used and they are opened by a breaker cam fitted to the crankshaft.

Replacement

1. Replacement of the points is easily accomplished by loosening the wire terminal nut, and disconnecting the primary wire and condenser wire from the points terminal. Remove the points base screw and lift them off. Remove the condenser securing screw.



2. Clean the contact surfaces of new points with a non-oily solvent prior to fitting.

3. When connecting the primary wire and condenser lead, be sure that the insulating washers for the points terminal are all present and correctly installed. If there is continuity between the primary wire and the engine (ground) when the points are open, the engine will not run.

Gapping

1. Clean the points if necessary before gapping.

2. Remove the spark plugs. Using a 17 mm wrench on the crankshaft nut, turn the engine counterclockwise until the points are open to their maximum gap. Check with a feeler gauge. Proper point gap is 0.3–0.4 mm (0.012–0.016 in.).

Loosen the base screw and move points with a screwdriver at the pry point to adjust gap

3. If adjustment is necessary, loosen the point base screw just enough to allow the points to be moved. Use a small slot-head screwdriver at the pry point provided to adjust the gap. Tighten the screw and recheck.

4. Clean off the points to remove any foreign matter which may have been deposited by the feeler gauge.

Lubrication

1. A felt pad is positioned to bear against the breaker cam and distribute lubricant.

2. Periodically, apply a bit of high temperature grease to the left-side of the pad. Do not overlubricate as this risks fouling the points.

IGNITION TIMING

Dynamic Timing

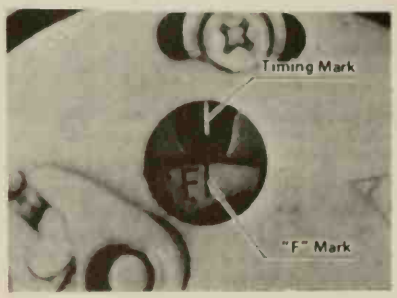
1. Clean and gap the breaker points.

2. Hook up the strobe light according to the manufacturer's instructions. The timing marks are visible through the inspection hole in the breaker plate.

3. Start the engine. At idle, the "F" mark on the timing advance mechanism must align with the stationary timing mark. At 3,000 rpm and above, the twin full-advance marks must align with the stationary timing mark.

Full advance timing marks

4. If adjustment is necessary, loosen the three breaker point base plate screws, and rotate the plate in either direction, as necessary, so that the marks align.



5. Once timing has been set for the full advance marks or for the "F" mark, the other should align as well. If only one of them can be brought into alignment, suspect trouble with the automatic timing advance mechanism.

6. When alignment is achieved, tighten the base plate screws and recheck.

Static Timing

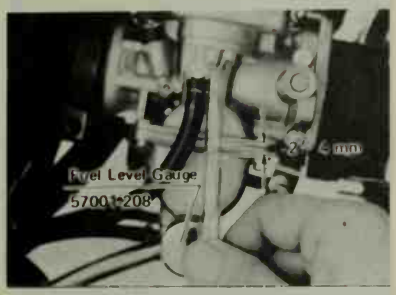
1. Clean and gap the points before checking the timing.

2. Hook up the test light or ohmmeter—one lead to ground, the other to the points wire terminal. Be sure that the ignition is off and the engine kill button is turned to an "Off" position.

Stationary advance timing mark "F"

3. Using a 17 mm wrench on the crankshaft nut, turn the engine over in the normal (counterclockwise) direction, until the "F" mark on the timing advance mechanism (visible through the inspection hole in the breaker base plate) comes into view.

4. Continue turning the engine over. As the "F" mark aligns with the stationary timing mark, the test light or meter should react, indicating that the points have begun to open.



5. If the points do not begin to open as these marks align, loosen the three breaker base plate screws after aligning the "F" mark and rotate the base plate in the direction necessary so that the points just begin to open when the marks align.

CARBURETORS

Adjusting Float Level

Generally, float level need not be adjusted unless fuel delivery problems have been noted, or if the machine has covered considerable mileage.

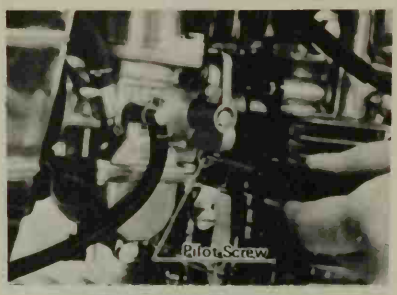
1. Drain the float bowls by removing the drain plugs.
2. Fit float level gauge No. 57001-208 to the float bowl. Turn on the fuel petcock.

Checking carburetor fuel level

Bend the tang to adjust fuel level

3. The fuel level should be 2–4 mm (0.08–0.12 in.) below the carburetor body-to-float bowl mating surface.
4. If adjustment is necessary, remove the carburetors, take off the float bowls, and remove the float assemblies.
5. Bend the float tang to correct the level. Bending the tang toward the carburetor body will lower the float level. Bending it down, or away from the carburetor body, will raise the float level.

Idle Speed and Mixture



NOTE: *These adjustments must be made when the engine is at operating temperature.*

1. If engine idling is very poor, the following procedure may be necessary: remove the carburetors from the manifolds. Turn the pulley as far as possible and check that both butterfly valves are parallel to the carburetor bores. If they are not, loosen the pulley stop screw locknut and turn the stop screw so that this is achieved. Tighten the locknut. Install the carburetors and check cable free-play. This procedure will not ordinarily be necessary, and most routine tune-ups can start with Step 2.
2. With the engine at operating temperature, back out the throttle stop screw until the engine idles at the lowest rpm at which it can run smoothly.

Use the pulley stop screw if butterfly valves are not parallel to the bores when opened fully

3. Turn each pilot screw in or out until the highest idle speed is reached.
4. Adjust the idle with the throttle stop screw to 1,100–1,300 rpm.
5. Turn each pilot screw in and out after noting their positions. If the idle speed rises when this is done, repeat Steps 2–4.

Adjusting the pilot screw

6. After the correct setting for each pilot screw has been determined, turn each one *in* 1/16 turn.
7. Rev the engine a few times and ensure that idle speed does not change. Check for proper cable free-play and operation.

Throttle Synchronization

1. Throttle synchronization is made easy with vacuum gauges 57001-127 and adapters 57001-401. Balance adjuster 57001-167 is also used. If the gauges are not available, refer to Steps 7 and following, below.
2. Fit the vacuum gauges to the carburetors.
3. With the engine at operating temperature and idling at 1,100–1,300 rpm, adjust the gauges so that needle flutter is less than 3 cm Hg. Standard vacuum should be 22–27 cm Hg. If the difference between the two gauges' readings is more than 1 cm Hg, stop the engine and remove the fuel tank.

Using the balance adjuster

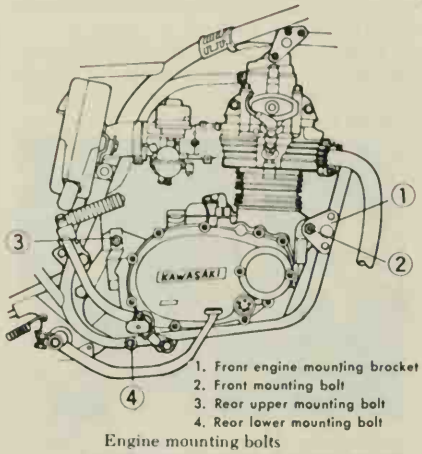
4. Use the balance adjuster on the balance adjuster screw so that vacuum is equalized. The motorcycle will run at this point on the gas left in the carburetors.
5. After equalizing vacuum, reinstall the tank, adjust both pilot screws by equal amounts so that vacuum is 22–27 cm Hg, then turn each in 1/16 turn.
6. Remove the gauges and adapters and use the throttle stop screw to adjust idle speed to 1,100–1,300 rpm.
7. If vacuum gauges are not available, check synchronization by placing a hand over the end of each muffler. Check that there is no difference in pressure or noise between the cylinders.
8. If there is, remove the gas tank, and adjust the balance adjuster screw to equalize the pressure. The engine will run on the fuel left in the carburetors. After equalizing pressure, install the tank and adjust the idle speed to 1,100–1,300 rpm.

Tune-Up Specifications

VALVE CLEARANCE (mm/in.)	
Intake	0.10/0.004
Exhaust	0.10/0.004
IGNITION SYSTEM	
Point gap (mm/in.)	0.3–0.4/0.012–0.016
Spark plug (NGK/ND)	
Standard	B-8ES/W24ES
Hot	B-7ES/W22ES
Cold	B-9ES/W27E
Spark plug gap (mm/in.)	0.7–0.8/0.028–0.032
CARBURETORS	
Idle speed (rpm)	1100–1300
Max. vacuum variation (cm Hg)	1.0
Vacuum at idle (cm Hg)	22–27
Pilot screw settings	1/16 turn from max rpm
COMPRESSION (psi)	
Standard	142–156
Service limit	107
Max. variation between cylinders	14

ENGINE AND TRANSMISSION

NOTE: *For engine component inspection techniques and procedures, refer to "Engine Rebuilding" under the "General Information" section.*



ENGINE REMOVAL AND INSTALLATION

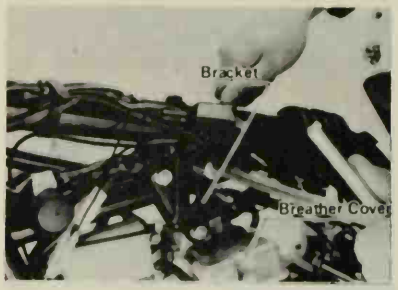
1. Drain the oil and filter.
2. Remove the gas tank. Disconnect the plug leads and loosen the spark plugs.
3. Disconnect the blue primary (breaker points) wire from the connector. Disconnect the tach cable.
4. Remove the left and right-side covers and disconnect the two electrical connectors. Disconnect the electric starter cable (if fitted) from the starter solenoid.
5. Remove the carburetors (refer to "Fuel System" if necessary for procedures).
6. Remove the exhaust system and passenger footpegs. Remove the left rider's footpeg and side stand spring. Remove the gearshift lever.
7. Remove the countershaft sprocket (left rear crankcase) cover. Remove the masterlink and disengage the chain from the countershaft sprocket.
8. Disconnect the rear brake light spring. Unscrew the switch adjusting nut until the portion beneath the mounting bracket can be squeezed, then push the switch out of the bracket.
9. Disconnect the tube from the breather. Remove the bracket bolts from the frame and breather cover (top engine mounting bolts). Unbolt and remove the breather cover.
10. Remove the engine mounting bolts. Raise the engine slightly as the bolts are removed to avoid thread damage. Note that the rear bolts are fitted with spacers and/or shims. Remove the left front engine mounting bracket. Move the clutch cable and sprocket cover out of the way.

11. Lift up the engine and remove it from the left-side of the frame, bringing the top out first.
12. Installation is the reverse of removal. Note the following points:

After installing the engine, fit the left front engine mounting bracket. Tighten the upper bolt and then the lower to 16–19 ft lbs.

Engine mounting bolts

13. Lift the engine slightly to install the mounting bolts. Note the rear bolts have spacers fitted between the frame and the left-side of the engine. The lower spacer may have shims added. After tightening the bolt to the proper torque (25–31 ft lbs), check to see if the spacer is tight. If not, add more shims to take up the clearance.
14. Install mounting bolt nuts with the spring side out, and tighten to 25–31 ft lbs.
15. Use a gasket sealer to hold the breather cover O-ring in place if necessary. Tighten cover bolts to 13–16.5 ft lbs.
16. When installing the sprocket cover, the oil guide seal guide should be used to avoid damage to the seal. Route wires in front of the upper mounting bolt spacer.
17. Use new exhaust pipe cylinder head gaskets. Install the shift lever so that it is aligned with the alternator cover lower right-hand screw.
18. When installing the carburetors, note that the cable should run along the right-hand side of the frame tube.
19. Adjust chain, brake light switch, etc.



CYLINDER HEAD

The cylinder head can be removed with the engine in the frame. Several special tools are needed for removal and installation.

The head assembly consists of the breather cover, cylinder head cover, head, camshaft, and valve train.

REMOVAL

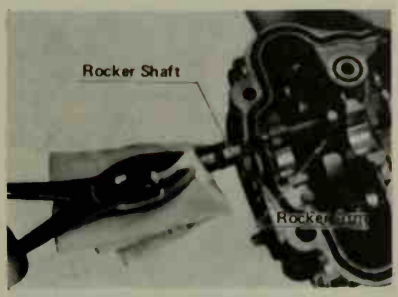
1. Remove the gas tank. Remove the breather cover bracket (three bolts). Disconnect the breather tube. Unbolt and remove the breather cover. Tap with a plastic mallet to free it if necessary.
2. Disconnect the tach cable. Remove the eight head cover nuts, and remove the cylinder head cover. Note the O-rings.
3. Remove the chain tensioner cap and O-ring. Remove the tensioner screws and pull out the tensioner assembly, complete.
4. Remove the breaker point cover. Using a 17 mm wrench on the crankshaft *nut*, turn the engine over, and unbolt the camshaft sprocket as the bolts become accessible. Disengage the cam chain from the sprocket.

Removing the breather cover bracket

Removing the cam chain tensioner

Removing the cam sprocket bolts

5. Loop a length of wire or something similar through the cam chain and secure it to a fixed point to prevent the chain from falling into the cylinder when the camshaft is removed. Remove the cam sprocket and cam.
6. Remove the exhaust system. Remove the left and right-side covers, and remove the carburetors. Refer to "Fuel System" for procedures if necessary.



Removing the cylinder head bolts

7. Remove the spark plugs. Disconnect the ignition coil leads and unbolt the coil bracket complete with coil.

8. Remove the cylinder head bolts with the special wrenches (57001-371/372). Bolts should be loosened gradually and in a cross pattern. Remove the cylinder head. Remove the head gasket.

Disassembly

1. To remove the rocker arms and shafts, remove the cap from each side of the cylinder head cover. Remove the nut from each rocker arm shaft, and remove the plates.

Extricating a rocker arm shaft

2. Pull out the rocker arm shafts with a pliers, protecting the shafts with a rag. Mark the shafts and rocker arms so that they will be installed in their original locations.

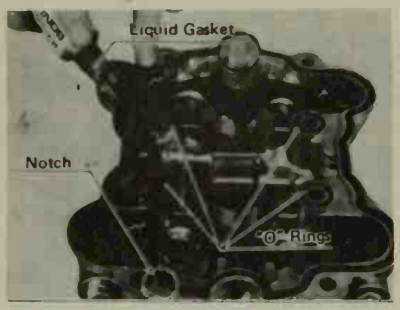
3. Remove the valves by compressing the springs and taking out the keepers. Remove the oil seals from the guides after removing the retaining clip.

Inspection

1. Refer to the specification charts at the end of this section for standard and service limits.

2. If removal of the valve guides is required, heat the head to 250–300° F (120–150° C), and drive out the guide. To install, make sure that an O-ring is fitted to the head side of the guide, and drive it in, heating the head as before.

3. Ream the guide after installation.



Assembly

The use of new O-rings and gaskets is recommended.

1. Lightly lubricate each rocker arm shaft O-ring and push the shafts into place, securing their rocker arms in the process. Note that the larger contact pad of the rocker arms ride on the camshaft. Turn each shaft so that the punch mark faces the center of the head cover. Install,

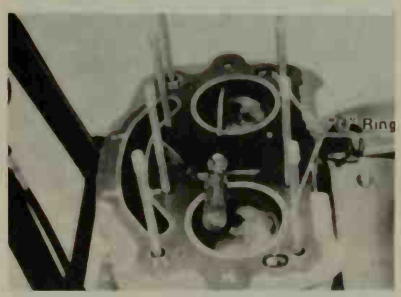
Be sure that the shafts are fitted with the punch marks facing the center of the head cover

Cover O-ring and gasket location

but do not tighten, the shaft nuts.

2. Check that all O-rings are in place in the head cover. Secure them with gasket sealer if necessary. Note that the large mating surface O-ring is fitted with a tab which must fit into a notch in the cover.

3. Assemble the valves, lubricating each valve with a small amount of high melting point grease before inserting it into its guide.



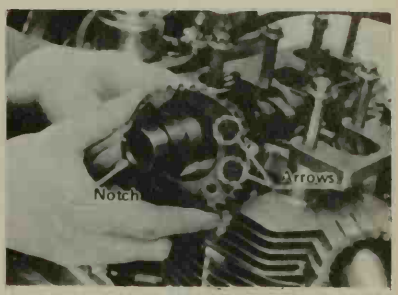
4. When installing the valve springs, note that both inner and out springs are progressively wound and are installed with the close coils toward the cylinder head.

Installation

1. Fit a new head gasket. Be sure that the O-rings on either side are in place.

2. Install the head, bringing the cam chain up through the passage in the head as it is lowered on the studs.

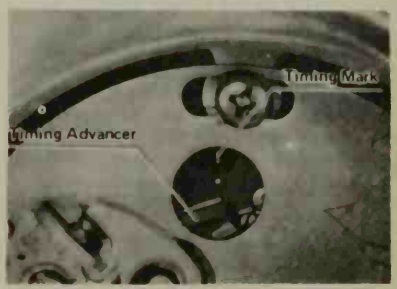
3. Install the cylinder head holding plates (57001-165), and tighten the stud nuts.



Cylinder head gasket and O-rings

Holding plates installed

4. Place the cam sprocket on the camshaft. The notched end of the camshaft is located on the *right-side* of the engine, and the side of the cam sprocket with arrows also faces the right-side of the engine.

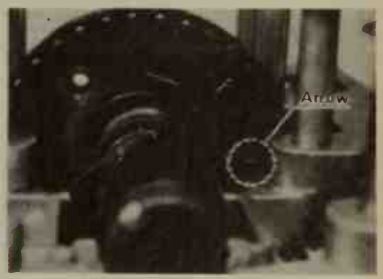


5. Lubricate the cam bearings and lobes, and slip the cam through the cam chain and fit the chain onto the sprocket.

The cam is installed with the notch on the right-side of the engine and the sprocket arrows face to the right as well

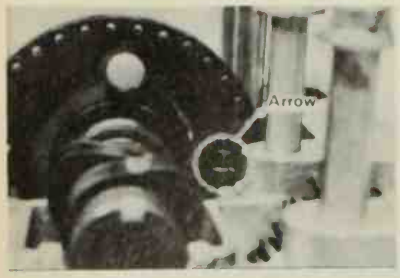
6. Turn the engine over so that the "T" mark aligns with the timing mark. Turn the engine *counterclockwise* exactly 90° past this point until the timing advance mechanism aligns with the timing mark as illustrated.

7. Disengage the cam chain from the sprocket, and turn the camshaft until the notch on the right end faces directly upward.



Align the timing advancer as shown to effect valve timing

8. The cam sprocket has two arrows. One is marked with a "T," the other is unmarked. Turn the sprocket so that the unmarked arrow points toward the front of the engine and is parallel with the head cover mating surface. Fit the cam chain onto the sprocket.



9. Position the sprocket up against the cam bolt holes. The bolt holes will not be aligned.

10. Hold the cam steady, and slowly turn the crankshaft until the bolt holes align. Fit the cam sprocket bolts which should be coated with a thread locking compound and tightened to 10.0–11.5 ft lbs.

11. Check that valve timing is correct. Turn the crankshaft so that the "T" mark on the timing advance mechanism is

The unmarked arrow aligns with the head surface when the timing advancer edge is aligned with the timing mark

The "T" mark on the sprocket aligns with the head surface when the timing advance "T" mark aligns with the timing mark

aligned with the stationary timing mark. At this position, the cam sprocket arrow marked "T" must be pointing toward the front of the engine and be parallel to the head cover mating surface. If it is not, valve timing is not correct, and must be done again.

12. Remove the cylinder head holding plates. Lubricate the components.

13. Turn the crankshaft so that the "T" mark on the timing advance mechanism is aligned with the timing mark.

14. Install the cylinder head cover, which has been prepared for installation in Steps 1–2. Fit the eight cover nuts, tightening them in the order shown gradually until the proper torque of 18–22 ft lbs is reached.

15. Install the four remaining head bolts and tighten them gradually and in the order shown to the proper torque: 8 mm bolts—18–22 ft lbs; 6 mm bolts—8–9.5 ft lbs.

16. Lubricate the tachometer gear with high melting-point grease, insert it, and connect the tach cable.

17. Refit the tensioner assembly. Assembly order is: pushrod, spring, gasket, holder, pushrod guide, and nut.

18. Install the breather cover, holding the O-ring in place with gasket sealer if necessary. Tighten the breather bolts gradually and in a cross pattern until a torque of 13–16.5 ft lbs is reached.

19. The remainder of the procedure is the reverse of removal. Adjust the valves and cam chain after assembly is complete.

CYLINDER AND PISTON

Removal

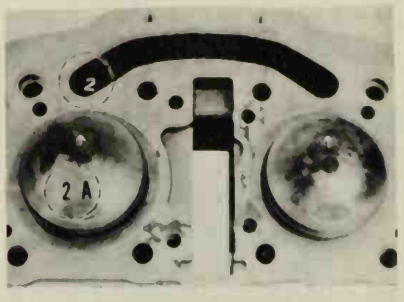
1. Remove the cylinder head components and cam chain tensioner as outlined in the preceding section.

2. Pull up the cylinders, taking care that the pistons do not hit the crankcases when they come out of the bores.

3. Remove the cylinder base gasket, noting the positions of the oil passage O-rings.

4. Wrap a clean rag around the base of the piston, and use a needlenose pliers to take out the wrist pin circlips.

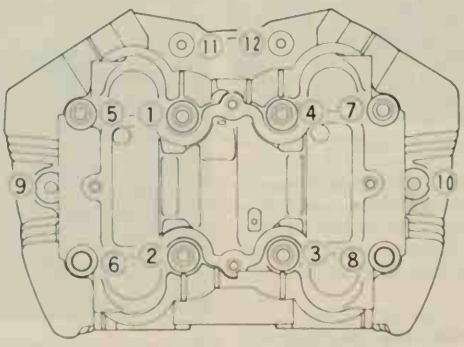
5. Push out the wrist pin. If the pin resists removal, the piston crown may be heated slightly. Alternately, use special factory tools 57001-910 and 57001-913.



Mark each piston for position so that it can be reinstalled in its own bore.

Inspection

1. Refer to the specifications chart at the end of this section for service limits. Note the following points:



Piston and pin marks

Piston and cylinder marks

a. Pistons are available in two oversizes: 0.5 mm and 1.0 mm. Measure piston diameter 5 mm (0.2 in.) from skirt bottom. Measure bore 10 mm (0.4 in.) and 60 mm (2.4 in.) from top; 25 mm (1 in.) from bottom;

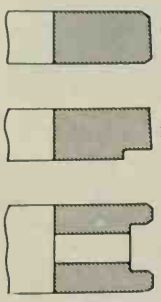
b. If boring is necessary, standard piston-cylinder clearance is 0.034–0.054 mm/0.001–0.002 in.;

Cylinder head and head cover bolt tightening sequence

c. In addition to fitted end-gap and side clearance, used rings should be checked for free end-gap to check for loss of tension;

d. When fitting new parts, try to fit a marked piston pin to a piston with an "A" mark on the crown, and an unmarked pin with an unmarked piston. Use pistons marked with "2" on the crown in cylinders marked in the same way, and fit unnumbered pistons into unnumbered cylinders.

Installation



1. Top and bottom compression rings are not interchangeable and must be installed as illustrated, and with the manufacturer's mark near the end-gap facing *upward.*

2. The arrow on the piston crown must face the exhaust port.

3. Use new wrist pin snap-rings in all cases.

Install rings with the mark facing upward

Note that the two compression rings are not interchangeable

4. Arrange ring end-gaps so that the top compression and oil ring gaps face the exhaust side and the second compression ring end-gap faces the intake side of the engine.

5. Fit a new cylinder base gasket, ensuring that the O-rings are in place. Fit new O-rings to the cylinders, if necessary.

6. Lightly lubricate the rings and piston skirts with motor oil. Use piston base 57001-340 to hold the pistons in place, and ring compressor 57001-921 and adapter A/57001-924 to squeeze the rings so that the cylinders may be installed.

7. Pull the cam chain through the cylinders as they are lowered down on the studs. Secure the chain so that it will not fall into the engine.

8. The rest of the procedure is the reverse of removal.

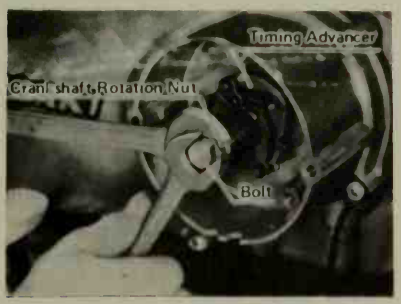
CRANKCASE COVER COMPONENTS

Right Crankcase Cover Components

The right crankcase cover houses the

breaker points assembly, centrifugal timing advance mechanism, clutch, primary drive components, external shift mechanism, and the oil pump.

Right Crankcase Cover



REMOVAL

1. Drain the oil. Remove the contact breaker cover. Scribe lines on the breaker plate relative to the securing screw positions so that ignition timing can be approximated when the plate is refitted. Remove the three screws and the plate.

2. Holding the 17 mm crankshaft nut with a wrench, break loose the crankshaft bolt. Remove it, and the timing advance mechanism.

3. Remove the right footpeg. Scribe a mark across the kick-starter lever and its shaft to mark its position, then remove the bolt and pull off the kick-starter lever.

4. Placing a pan beneath the cover to catch any oil residue, remove the 12 cover screws and pull off the cover, using a plastic mallet to break it loose if necessary.

Removing the crankshaft bolt

INSTALLATION

1. Use a new cover gasket. Check the condition of the kick-starter and crankshaft oil seals in the cover, and replace them if necessary. Grease the lips of the seals before installation.

2. When installing the cover, use kick-starter oil seal guide 57001-265 to prevent damage to this seal during installation. Tighten the cover screws evenly and securely.

3. When fitting the timing advance mechanism, note that its notch fits with the pin on the end of the crankshaft. Tighten the bolt to 16.5–19.5 ft lbs.

4. The remainder of the procedure is the reverse of removal. Reset the ignition timing.

Timing Advance Mechanism

REMOVAL

1. Remove the contact breaker cover. Scribe lines on the breaker plate relative to the securing screw positions, so that ignition timing can be approximated when the plate is refitted. Remove the three screws and the plate.

2. Holding the 17 mm crankshaft nut with a wrench, break loose the crankshaft bolt. Remove it, and the timing advance mechanism.

INSPECTION

1. Check for free movement of the mechanism and for proper spring tension. When turned against its stop and released, the breaker cam must return quickly to the original position.

2. If it does not, lubricate the mechanism with penetrating oil. If no improvement is noted, replace the springs.

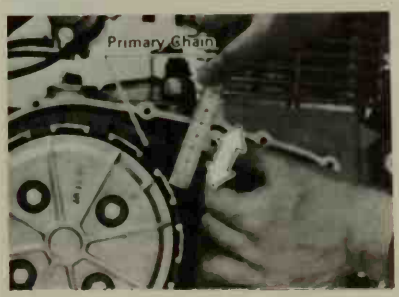
3. To disassemble the unit, pull off the breaker cam. Remove the two "C" rings, washers, and weights. Remove the thrust washers. Lubricate the shaft and inside of the cam with some high melting point grease.

4. When assembling, align the mark on the breaker cam with the cut-out notch on the mechanism body.

When assembling the timing advance mechanism, align the mark with the notch

INSTALLATION

1. Installation is the reverse of removal. Align the notch in the mechanism with the pin on the crankshaft.



2. Tighten the crankshaft bolt to 16.5–19.5 ft lbs.

Clutch and Primary Drive

REMOVAL

Before removing the components, check primary chain wear.

The primary chain is allowed a maximum of 20 mm (0.8 in.) of total up and down movement which is measured in the middle of the upper chain run. If movement exceeds this amount, replace the chain.

Checking primary chain wear

If replacement is necessary, use "Tsubakimoto Hy-Vo" No. 3/8P-5/8W 74-link chain only.

1. Remove the right crankcase cover as outlined in the preceding procedure.

2. Remove the clutch spring bolts, washers, and springs. Remove the pressure plate. Remove the pusher. Tilt the motorcycle to the right so that the steel ball comes out of the clutch shaft.

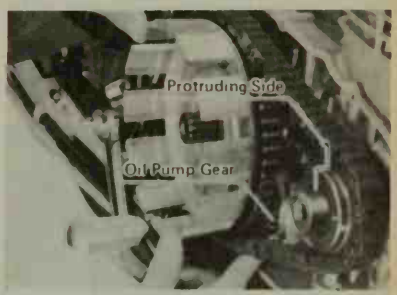
Removing the oil pump drive gear

3. Remove the clutch hub circlip and the shims behind it. Remove the clutch plates and the clutch hub. Note the thrust washer behind the hub.

4. Remove the circlip from the crankshaft (primary) gear. Pull off the clutch housing, chain, and crankshaft gear together.

5. Remove the oil pump drive gear from the back of the clutch housing, if desired, by removing the circlip. Note the locating pin.

INSPECTION



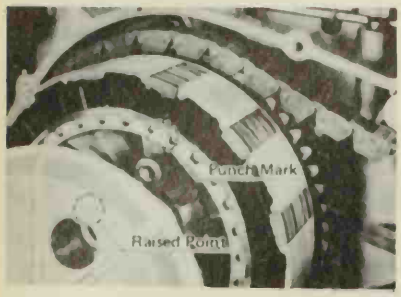
1. Check the clutch and gears as outlined in "Engine Rebuilding" and by referring to the specifications at the end of this section.

2. Check chain guide thickness. Standard is 7.5 mm (0.3 in.). Serviceable limit is 3.5 mm (0.14 in.).

INSTALLATION

1. Fit the oil pump drive gear onto the clutch housing, noting that the protruding side of the gear faces the housing.

2. Assemble the crankshaft gear, chain, and clutch housing. Note that the protruding side of the crankshaft gear faces *out*. Fit the assembly, rotating the oil pump gear by hand if necessary so that it meshes with the drive gear. Install the crankshaft gear circlip.



Install the crankshaft primary gear with the protruding side outward

3. Fit the thick thrust washer to the clutch assembly, followed by the hub. Install the shims and the clutch hub circlip. There should be no axial play of the clutch hub on its shaft. If there is, remove the circlip, and add more shims until the play is taken up.

4. Install the clutch plates in the following order: friction plate, steel ring, steel plate, and alternating in this manner, fitting a steel ring last.

5. Install the steel ball and the pusher.

6. Install the pressure plate, aligning the marks on the plate and the clutch hub. Install the springs, washers, and

Align the marks on the pressure plate and clutch hub

spring bolts, tightening them evenly and in a cross pattern.

7. The remainder of the procedure is the reverse of removal.

Oil Pump

REMOVAL

1. Remove the right crankcase cover and the clutch and primary drive assembly. Refer to the preceding procedures.

2. Remove the four oil pump screws and pull off the pump. Note the O-rings in the crankcase.

INSPECTION

Refer to "Lubrication System."

INSTALLATION

1. Installation is the reverse of removal.

2. Lubricate the pump with motor oil before installation.

Shift Mechanism

The shift mechanism in the right crankcase cover consists of the shift shaft, return spring, and shift arm or pawl.

REMOVAL

1. Remove the right crankcase and the clutch and primary drive assembly. Refer to the preceding procedures.

2. Remove the left rider footpeg. Remove the side stand and spring. Remove the gearshift lever.

Removing the shift mechanism stopper

3. Remove the left rear crankcase (engine sprocket) cover.

4. Remove the shift mechanism stopper. Disengage the fingers of the shifter pawl from the shift drum and pull out the shaft.

INSTALLATION

1. Be sure that the shifter return spring is properly installed with the spring arms on either side of the return spring pin.

2. Use oil seal guide 57001-264 to protect the shift shaft oil seals in the crankcase and the engine sprocket cover when installing the shift shaft. Engage the pawl with the shift drum pins.

3. Use thread locking compound on the shift mechanism stopper screws.

Left Crankcase Cover Components

The left crankcase covers house the engine (countershaft) sprocket, the clutch release mechanism, the alternator, and the electric starter sprocket and chain (on "D" models).

Left Crankcase Covers

REMOVAL AND INSTALLATION

1. Remove the left rider's peg. Remove the sidestand and spring. Remove the shift lever.

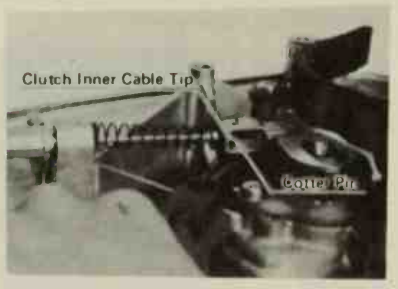
2. Remove the four screws and take off the sprocket cover.

3. To remove the alternator cover, first remove the sprocket cover (Steps 1 and 2).

4. Remove the right-side frame cover and disconnect the alternator field coil leads from the connector.

5. Remove the wiring guide just above the countershaft sprocket.

6. Remove the starter motor cover and gasket. Remove the eight alternator cover screws and take off the cover. Disconnect the oil pressure and neutral indicator leads.



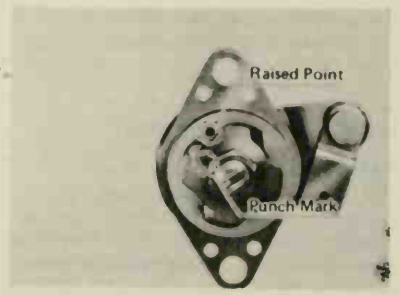
7. Installation is the reverse of removal. Use shift shaft oil seal guide 57001-264 when installing the countershaft sprocket cover. Be sure that the electrical wiring is correctly routed.

Clutch Release Mechanism

REMOVAL AND INSTALLATION

1. The clutch release mechanism is incorporated in the countershaft sprocket cover.

2. Remove the sprocket cover. Remove the cotter pin from the clutch cable fitting, and disengage the cable from the fitting, and from the cover.



Disconnecting the clutch cable from the fitting

3. Remove the chain guide screws.

4. Remove the two clutch release outer gear screws and separate the two gears.

5. Clean the release mechanism in solvent, dry, and lubricate thoroughly with grease.

6. Assemble the release mechanism, fitting the worm gears together so that, as they begin to mesh, the raised point on the outer gear aligns with the punch mark on the inner gear.

The raised point and punch mark should align as the gears begin to mesh

Clutch release mechanism installation

7. Use thread locking compound on the outer gear screws. Install the mechanism as shown.

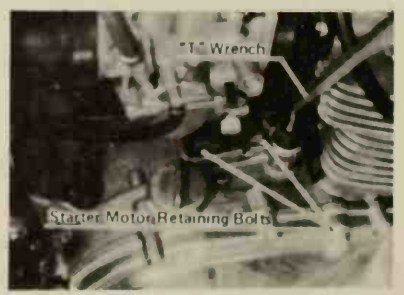
8. The remainder of installation is the reverse of removal.

Countershaft Sprocket

REMOVAL AND INSTALLATION

1. Remove the countershaft sprocket cover.

2. If special engine sprocket holder 56019-040 is available, disconnect the chain, bend down the tab on the sprocket nut lockwasher, and remove the nut.

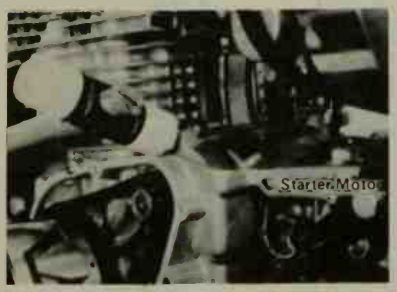


3. If it is not available, place the transmission in gear, bend down the tab on the sprocket washer, and remove the sprocket nut, applying the rear brake if necessary to hold the sprocket.

4. To install, tighten the sprocket nut to 87–105 ft lbs and bend down the washer tab. If the chain was disconnected, be sure to install the masterlink spring clip with the closed end facing the direction of chain rotation.

Alternator and Starter Assembly

REMOVAL



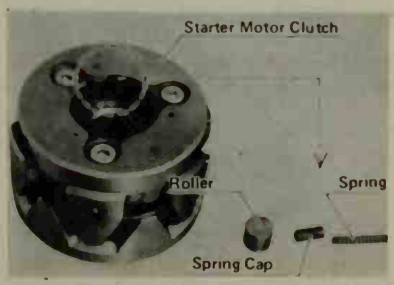
1. Remove both left-side covers as outlined in the preceding procedures.

Removing the starter motor bolts

2. To remove the starter motor, first remove the cover and disconnect the lead at the motor.
3. Remove the two 10 mm bolts on the right-side of the starter motor body.
4. Tap lightly on the starter motor body with a plastic mallet to move it to the right and disengage the shaft from the gear.

CAUTION: *Do not tap the motor shaft itself.*

Tapping out the starter motor



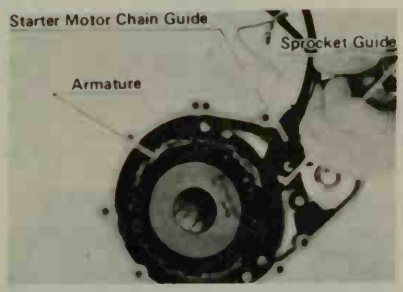
5. To remove the alternator rotor, hold the rotor steady with the special tool (alternately, engage the transmission and apply the rear brake to lock the crankshaft, and remove the rotor bolt by turning it in a *clockwise* direction).

CAUTION: *The rotor bolt is a LEFT-HAND thread.*

6. Remove the rotor and starter clutch assembly using special puller 57001-254 while holding the rotor in place. Note the thrust washer behind the rotor.
7. Pull off the starter chain and sprocket.
8. The field coil and alternator armature windings are in the cover. To remove them (not necessary for testing), remove the starter motor chain guide and sprocket guide. Remove the three armature allen bolts and remove the armature. Remove the three field coil allen bolts on the outer side of the cover and remove the field coil.

INSPECTION

1. For alternator and starter motor tests, refer to "Electrical System."
2. Disassembly of the starter clutch is not necessary unless it has been malfunctioning. To check operation of the starter clutch, fit the sprocket and rotor assembly to the crankshaft. When the rotor is turned, by hand, in a counterclockwise direction, the sprocket should turn as well. If the rotor is turned in the clockwise direction, the sprocket should not turn.



Starter clutch components

To disassemble the starter clutch, remove the three allen screws, and take out the springs, spring caps, and rotors. Check for wear of the rollers.

3. Check the starter motor chain by measuring its length. Extend the chain by stretching it with a force of about 10 lbs. A twenty-link length of chain (standard) measures 155.5 mm (6.1 in.); service limit is 157.8 mm (6.2 in.)

INSTALLATION

1. Fit the starter clutch to the rotor, using thread locking compound on the bolts and tightening to 24–27 ft lbs.
2. Install the field coil, use thread locking compound on the bolts and tighten to 5.1–5.8 ft lbs. Use the same procedure and torque on the armature bolts. Fit all wiring into their grommets and properly fit the grommets in the case.

Installing the sprocket guide

3. Use thread locking compound when installing the sprocket guide and starter motor chain guide. The sprocket guide bends outward.
4. Put a little oil on the starter motor O-ring, and install the starter motor. Install the sprockets and chain.
5. Put some high melting point grease on the rotor thrust washer and put it behind the rotor, installing the rotor assembly on the crankshaft. Install the rotor bolt (left-hand thread), and tighten it to 47–51 ft lbs while holding the rotor in place.
6. The remainder of the procedure is the reverse of removal.

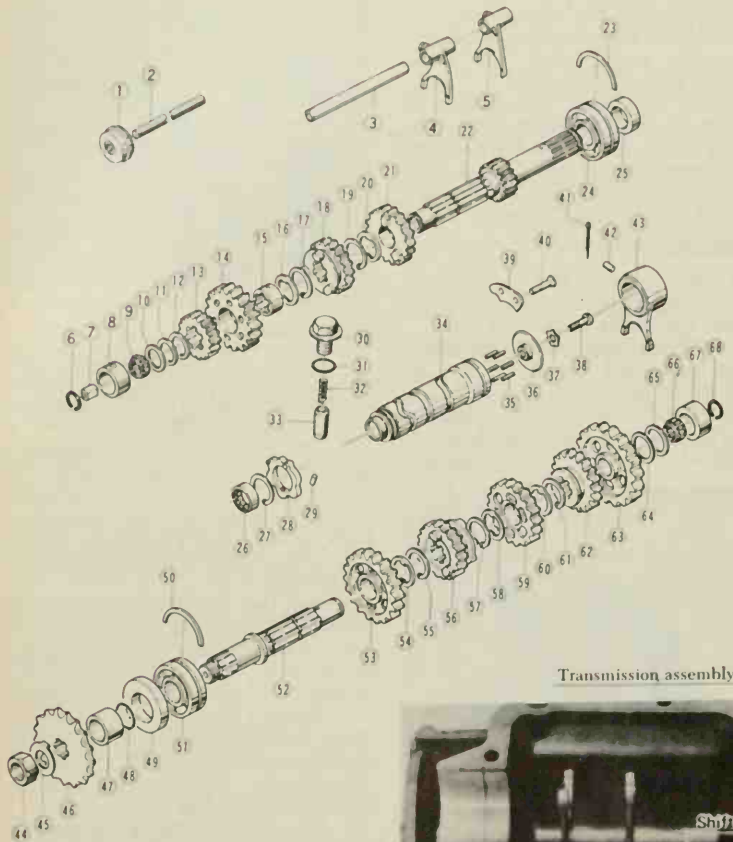
Lower End and Transmission

Engine removal is required for these components: crankshaft, transmission, shift drum assembly, balancer assembly, and kick-starter.

Removal of the top end components is required for crankshaft service, but the top end may be left in place for service and inspection of the kick-starter, transmission, or balancer.

Splitting the Crankcase

1. Drain the oil and remove the filter. Remove the engine from the frame. If crankshaft service is required, remove the top end components. Refer to the preceding procedures.
2. Remove the crankcase covers and all of the components therein: clutch and primary drive, external shift mechanism, countershaft sprocket, starter motor, and alternator assembly.
3. Remove the six upper crankcase half bolts and the carburetor overflow/breather tube guide.
4. Turn the engine upside down and remove the fourteen lower crankcase half bolts. Remove the lower case half, tapping carefully with a plastic mallet to free it if necessary.



The lower case half will come away with the kick-starter shaft. The other components will remain in the upper case half.

Transmission

1. Check the gears in place. Check gear backlash. Standard is 0.06–0.23 mm (0.0024–0.0092 in.), while the serviceable limit is 0.3 mm (0.012 in.).
2. To remove the transmission, lift the shafts and gears together out of the case.
3. Disassembly of the transmission shafts must be done carefully. Lay out each component as it is removed for ease of assembly.
4. For the mainshaft, take out the clutch pushrod and oil seal. Remove the shaft needle bearing outer race. Remove the circlip and take off the needle bearing and any shims fitted.
5. Remove the 2d and 5th gears, the copper bushing and splined washer. Remove the circlip followed by 3rd gear.
6. Remove the circlip, splined washers, and 4th gear.
7. Remove the bushing and shaft ball bearing together using the special puller.
8. To disassemble the countershaft, remove the needle bearing outer race, circlip, needle bearing, and shim(s).
9. Remove the 1st and 4th gears, splined washer, 3rd gear, splined washer, circlip, and 5th gear.
10. Remove the circlip, splined washer, and 2d gear. Remove the oil seal, collar, and O-ring. Remove the shaft ball bearing with the special tool.
11. Check gear-shaft clearances.
12. Assembly is the reverse of disassembly. Refer to the exploded view for part locations. New circlips should be used, and special tool 57001-380 should be used to install circlips without damage.
13. After assembly of the shafts, check side play. If evident, use shims as necessary on the engine side of the needle bearings to eliminate play. Shaft ball bearings must be pressed into place.

Shift Drum

1. Remove the transmission shafts.
2. Remove the shift drum stopper.
3. Remove the shift drum positioning bolt, O-ring, spring, and plunger on top of the upper crankcase half.
4. Remove the cotter pin and guide pin from the shift fork (3rd gear), which rides on the shift drum. Pull out the shift drum, and remove the operating plate circlip, operating plate, and shift fork.
5. Pull out the shift rod and the two remaining shift forks. They are not interchangeable. Note positions.
6. Check all parts for wear.
7. Insert the shift rod into the crankcase and through the two shift forks. The

1. Oil seal

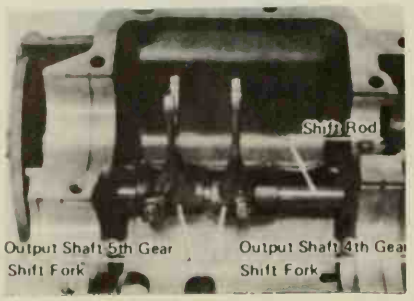
Transmission assembly



Removing the shift drum stopper

Removing the shift drum positioning bolt assembly

Removing the shift drum

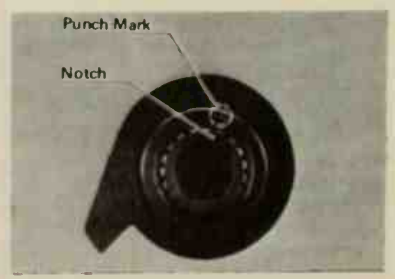
Shift fork positions

Shift drum operating plate installation. The nub faces out.

shift forks are not interchangeable. Note that the fork on which the guide pin is located in the center of the fork is located on the clutch side of the engine.

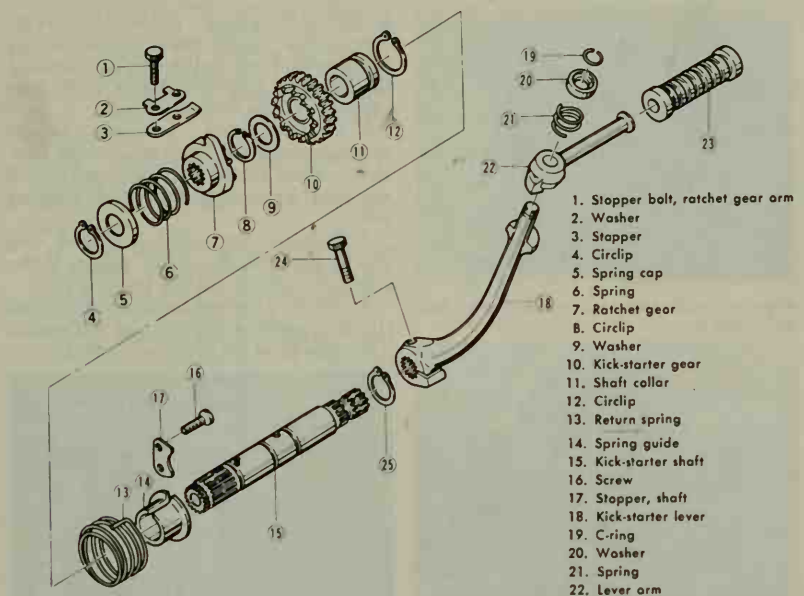
8. Insert the shift drum into the crankcase fitting the shift fork as this is done. The pin housing on the shift fork faces the crankshaft.

9. Install the operating plate pin, if it was removed, and fit the operating plate, nub facing out. Install the circlip.



10. Insert the shift fork guide pin, cotter pin, and secure the cotter pin.

11. Fully install the shift drum and engage the guide pins for the other two shift forks with the drum grooves.



12. Install the shift drum stopper screws, which should be peened for security. Install the shift drum positioning bolt components after turning the drum, if necessary, so that the plunger is properly in place.

Kick-Starter

1. Bend up the tabs on the lockplate of the ratchet gear arm stopper bolts, and remove the bolts and stopper.
2. Remove the spring guide circlip.
3. Remove the spring guide. Remove the return spring.
4. Remove the kick-starter shaft collar circlip. Remove the shaft stopper and collar.
5. Remove the kick-starter shaft.
6. Remove the gear and thrust washer. Remove the spring side circlip, and take off the spring cap and spring.
7. Remove the ratchet gear and the other circlip.
8. Check all parts for wear.
9. Assembly is the reverse of disassembly. When fitting the ratchet gear, align the punch mark on the gear with the notch on the shaft.
10. When fitting the return spring, turn the shaft as far as possible clockwise, insert one end of the return spring into the crankcase and the other end into the kick-

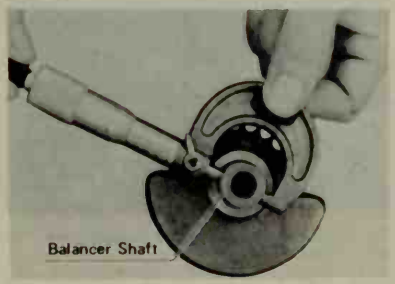
starter shaft. Hold the spring in this position, and fit the spring guide.

11. Use a bit of high melting point grease on the inside of the collar. Peen the shaft stopper screws for security. Bend down the tabs on the ratchet gear arm stopper bolt lockplate.

Balancer

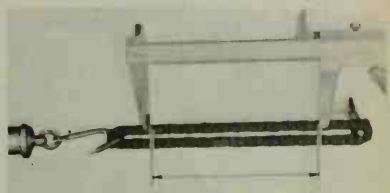
REMOVAL

1. Remove the four bolts and two screws from the crankshaft bushing cap. Note that the cap has an arrow pointing toward the front of the engine, and it must be refitted in the same way.
2. Remove the balancer chain guide.



Removing the crankshaft bushing cap

3. Remove the balancer holder bolts, tap the holders lightly with a plastic mallet to free them, if necessary; then lift the entire balancer assembly away.
4. If disassembly of the unit is desired, remove the chain. Remove the holders from each balance weight and the shims.
5. Tap off the sprockets with a plastic mallet. Remove the springs and pins. Remove the bolts, and separate the weights from their shafts.

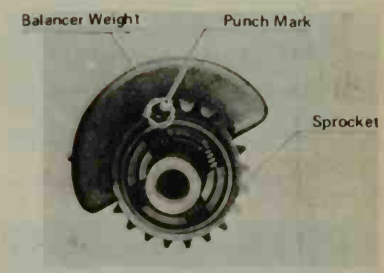


INSPECTION

1. Measure the diameters of the balancer shafts and the inside diameters of the holders. Compare to the serviceable limits.

Measuring balancer shaft diameter

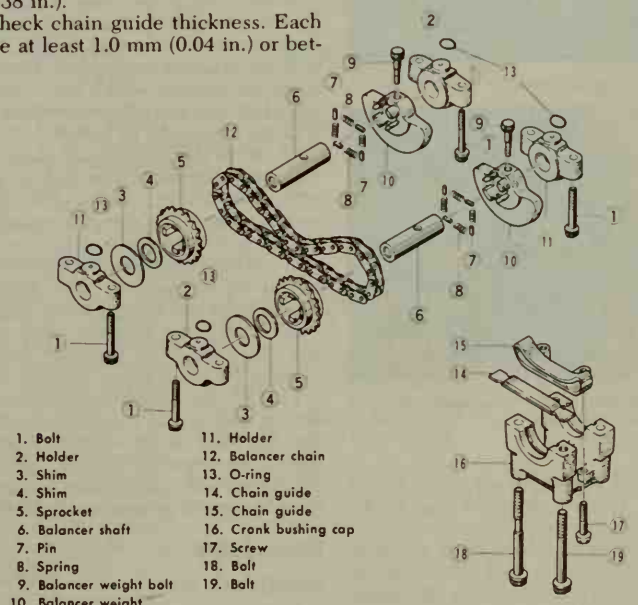
2. Apply a force of about 10 lbs to stretch the balancer chain and measure a 20-link length. Standard length is 160 mm (6.30 in.). Serviceable limit is 162.4 mm (6.38 in.).
3. Check chain guide thickness. Each must be at least 1.0 mm (0.04 in.) or better.



Measure a 20-link length.

Checking the balancer chain for wear

4. Check balancer spring free-length. Standard free-length is 9.8–10.4 mm (0.39–0.41 in.). Serviceable limit is 9.0 mm (0.35 in.).



INSTALLATION

1. Oil each shaft and fit them into their weights. Line up the larger shaft hole with the hole in the weight and fit the bolt, securing it with thread locking compound and torquing to 7.9–9.5 ft lbs.
2. Install the springs and pins. Fit the sprocket. The punch mark on the sprocket must face away from the balancer weight. The sprocket must be installed as shown. There are four possible ways to install it. Only one is correct.

Sprocket installed correctly

3. Install the sprocket side shims. The smaller diameter shim is installed first. Fit the holders onto the shaft. Note that the machined side of each holder faces the weight.

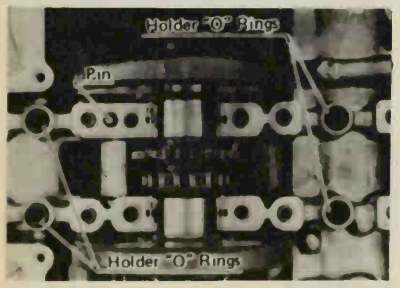
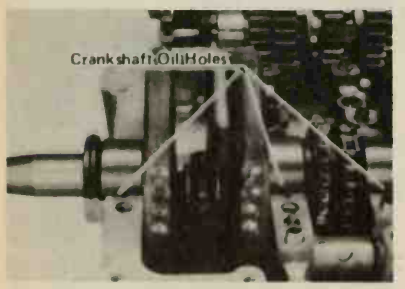
19. Bolt

Balancer assembly

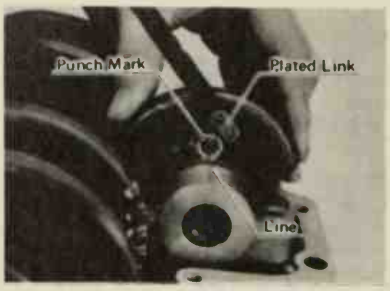


Install holders with the machined side facing the weight

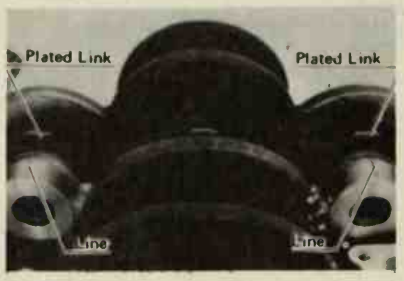


The chromed links must align with the sprocket punch marks

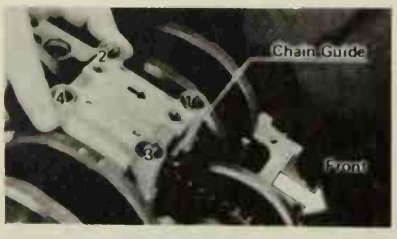
Install the assembly with the holder arrows pointing outward



The pin and O-rings must be in place



Turn the crankshaft so that the oil holes align with the crankcase mating surface



4. Install the chain on the balancer sprockets. The two chromed links on the chain must align with the punch marks on the sprocket tooth of each sprocket. Turn the holders so that the arrow on each holder points away from the crankshaft.

Align the chrome-plated link, sprocket punch mark, and holder line

Balancer assembly correctly installed. The weights must be directly upright.

The crankshaft bushing cap is installed with the arrow facing the front of the engine

5. Check that the holder O-rings and the pin are in place in the crankcase.

6. Turn the crankshaft so that the oil holes are even with the upper crankcase mating surface, as shown, and facing the front of the engine.

7. Holding the balancer assembly taut after alignment (Step 4), place one unit in position in the crankcase. Turn the sprocket punch mark so that it aligns with the mark on the holders. Engage the balancer chain with the crankshaft sprocket, and install the remaining unit, aligning the marks as before.

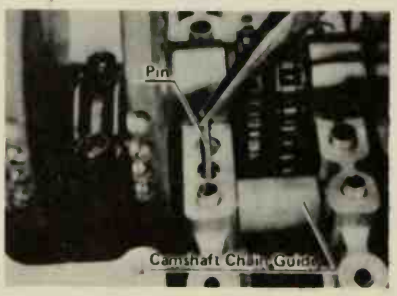
8. With the balancer in place, check that each chrome chain link is aligned with the holder marks. The balance weights must be directly upright, not cocked to either side.

9. Make sure that each holder is well-seated in its locating pin. Install the holder bolts and tighten to 10–11.5 ft lbs.

10. Install the balancer chain guides: one under the upper chain run, one in the crankshaft bushing cap.

11. Oil the crankshaft bushing cap lightly, and install it with the arrow facing the front of the engine. Install the screws, securing them with thread locking compound. Tighten the bushing cap-bolts in a cross pattern to 18–22 ft lbs.

Cranksahft



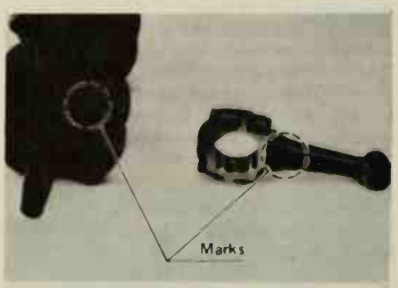
REMOVAL

1. Remove the top end components, including the pistons. Remove the crankcase cover components and split the crankcases. Remove the transmission and the balancer assembly. Refer to the preceding sections for procedures.

2. Remove any balancer holder O-rings which are loose to prevent loss. Remove the pin in the crankcase which secures the camshaft chain guide locating pin.

3. Remove the crankshaft and cam chain. Remove the chain guide, if desired, by pulling out the locating pin.

4. Remove the connecting rods, noting the alignment of the cap and rod marks. The caps must be installed correctly.



Removing the chain guide pin

INSPECTION

1. Check that the rods are not bent or twisted.

2. Check the condition of the rod bearings. Use Plastigage® to measure rod-crankshaft journal clearance which is set at 0.041–0.071 mm (0.0016–0.0027 in.). Serviceable limit is 0.1 mm (0.0039 in.).

Con rod and crankshaft marks

3. Rods and crankshaft journals are "sized." A mark, or a lack of a mark, on the rods is significant. Crankshaft journals will also have a mark or no mark—but this is not significant, since they refer to factory dimensions. Since the journals wear, they must be measured, and marked accordingly. Proceed as follows:

a. Measure the diameter of the rod journals. If diameter is 35.994–36.000 mm (1.4171–1.4173 in.), mark the journal ("1").

If diameter is 35.984–35.994 mm (1.4167–1.4171 in.), leave the journal unmarked.

NOTE: *Ignore any marks already present on the crankshaft.*

b. Note the mark or lack of mark on the rods. An unmarked rod has a big end diameter of 39.000–39.010 mm (1.5354–1.5358 in.). A marked rod has a diameter of 39.010–39.016 mm (1.5358–1.5361 in.).

This diameter is measured with the rod cap in place and properly torqued. It does not include the bearing inserts;

c. Bearing inserts are color coded, and are available in three thicknesses:
Blue 1.485–1.490 mm (0.05846–0.05866 in.)
Black 1.480–1.485 mm (0.05827–0.05846 in.)
Brown 1.475–1.480 mm (0.5856–0.05827 in.)

d. After measuring and marking the crankshaft and noting the con rod marks, select the proper bearing insert according to the following:

If the crank journal is marked, and the rod is not, use the BROWN inserts.

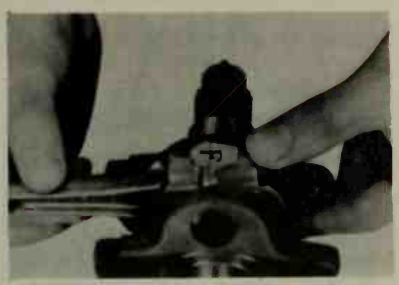
If both journal and rod are marked, use the BLACK inserts.

If the crank is unmarked, but the rod is, use the BLUE inserts.

If neither is marked, use the BLACK inserts.

4. After fitting new bearing inserts, check connecting rod side clearance.

5. Check crankshaft run-out.



6. Measure crankshaft main bearing diameter. Check main bearing clearance with Plastigage® and replace the main bearing inserts if excessive.

7. Install the bushing cap and tighten the bolts to the proper torque (18–22 ft lbs). Measure crankshaft thrust clearance as shown. Measure between the bushing cap and center portion of the flywheel. Standard is 0.10–0.20 mm (0.0039–0.0078 in.). If greater than 0.45 mm (0.0177 in.), the crankcases and the bushing cap must be replaced together.

NOTE: *Cap and cases are line-bored when assembled at the factory, and must therefore be replaced in sets.*

ASSEMBLY

1. Lubricate the rod bearings, and install the rods on the crankshaft, ensuring that the rod and cap marks align as shown. Oil the rod bolts and tighten the nuts to 24–27 ft lbs.

The rod caps must be fitted so that the marks align

Crankcase Assembly

1. Clean the case mating surfaces thoroughly. Blow out oil passages.

2. Install the main bearings inserts. Be sure that these and all other components are oiled during assembly.

3. Check that the transmission shaft locating pins and bearing set rings are in place.

4. If the camshaft chain guide was removed, install it. The grooved end of the guide pin goes toward the alternator side of the engine.

Engine and Transmission Specifications

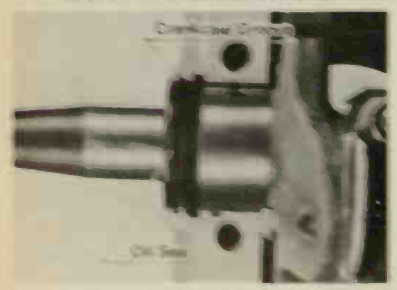
Check that the set rings and locating pins are in place



The grooved end of the chain guide locating pin must be on the dynamo (alternator) side

Lower crankcase half components

Upper crankcase half components

The alternator side oil seal is installed with the spring side facing the crankshaft. The ridge on the seal fits into the groove

5. Install the crank and cam chain. Note that the alternator side of the crankshaft is fitted with an oil seal which must be installed with the spring side facing toward the crank. The ridge on the seal must fit into the groove in the crankcase.

6. Install the cam chain guide pin.

7. Check that the oil passage O-ring and the balancer assembly holder O-rings are in place. Install the balancer assembly.

8. Install the crankshaft bushing cap with chain guide, arrow pointing toward the front of the engine. Install the cap-screw, securing them with thread locking compound. Install the cagbolts, tightening to 18–22 ft lbs in a cross pattern.

9. Install the shift drum and forks. Install the transmission shafts and gears. Check that the pushrod oil seal is in place. Be sure that the output (countershaft), oil cap is in place on the right-side of the shaft (lower crankcase half). Install the kick-starter assembly.

10. Apply a liquid gasket compound to the upper case half. Install the lower case half. Tighten the lower case 8 mm bolts in the order shown. Proper torque is 18–22 ft lbs. Tighten the bolts gradually and evenly until the proper torque is reached. Tighten the 6 mm bolts gradually and in the order shown to 5.8–7.3 ft lbs.

11. Tighten the upper crankcase bolts to 5.8–7.3 ft lbs.

12. The remainder of the procedure is the reverse of disassembly. Refer to the preceding sections.

Engine and Transmission Specifications (cont.)

	Standard (mm/in.)	Serviceable Limit (mm/in.)
Shift fork guide pin diameter		
2nd	7.985–8.000/0.3144–0.3150	7.93/0.312

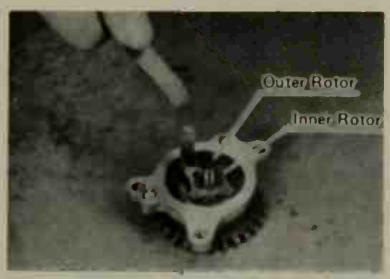
Crankcase bolt tightening order

LUBRICATION SYSTEM

OIL PRESSURE

1. Remove the oil pressure indicator switch, and connect the oil pressure gauge adapter (57001-400).
2. At engine operating temperature, pressure should be 57 psi at 4,000 rpm.
3. If pressure is low, check the oil pump.

Checking oil pressure

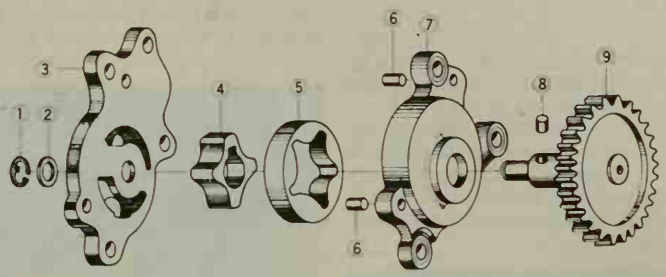


OIL PUMP

Removal

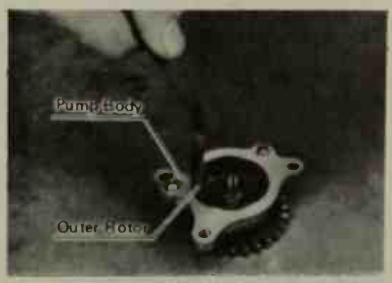
1. The pump is located on the right-side of the lower crankcase half. Access to the pump is obtained by removing the clutch. Refer to "Engine and Transmission" for procedures, if necessary.

Inspection



1. Measure inner-to-outer rotor clearance. Standard is 0.025–0.115 mm (0.0010–0.0045 in.). Replace the rotors if clearance exceeds 0.21 mm (0.0083 in.).
2. Check wear to the sides of the rotors by laying a straightedge across the pump and checking clearance between the straightedge and the rotors. Standard clearance is 0.03–0.09 mm (0.0012–0.0035 in.). Replace the rotors if clearance exceeds 0.15 mm (0.0059 in.).

Measuring inner rotor-to-outer rotor clearance

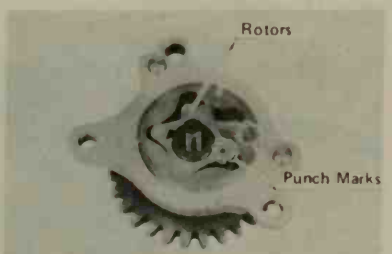


Checking rotor side wear

1. C-ring
2. Washer
3. Body inner half
4. Inner rotor
5. Outer rotor
6. Pin
7. Body outer half
8. Pin
9. Pump drive gear

Oil pump components

Checking outer rotor-to-pump body clearance



3. Check the clearance between the outer rotor and the pump body. Standard clearance is 0.10–0.15 mm (0.004–0.006 in.). Replace either the outer rotor or the pump body (depending on which is worn), if clearance exceeds 0.25 mm (0.0098 in.).

Disassembly

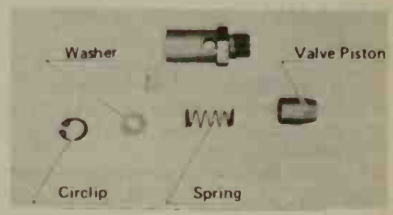
1. Remove the C-ring and washer from the gear shaft.
2. Separate the body halves and remove the rotors.
3. Remove the shaft pin to remove the gear from the body half.

Assembly

1. Assembly is the reverse of disassembly. Note that the sides of the rotors with the punch marks face away from the gear when installed.

Install rotors with the punch marks facing outward

Installation

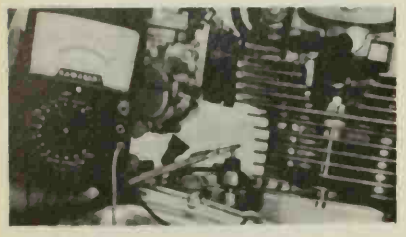


1. Oil the pump internals thoroughly before installation. Use new O-rings if necessary. Be sure that the O-rings are in place.

OIL PRESSURE RELIEF VALVE

1. The oil pressure relief valve is located in the lower crankcase half.
2. To remove the valve, separate the case halves as outlined in "Engine and Transmission." Unscrew the valve from the case.
3. To disassemble the valve, remove the circlip, and take out the washer, spring, and valve piston.

Removing the oil pressure relief valve



Pressure relief valve components

4. Measure the diameter of the piston. Measure the inside diameter of the valve body. Standard clearance is 0.020–0.103 mm (0.0008–0.0041 in.). Replace either the piston or the body (depending on which is worn), if clearance exceeds 0.13 mm (0.0051 in.).
5. Measure the free-length of the spring. Standard value is 20.6 mm (0.811 in.). Serviceable limit is 19.0 mm (0.748 in.).
6. Assembly is the reverse of disassembly. Use thread locking compound when installing the valve in the crankcase.

OIL PRESSURE INDICATOR SWITCH

1. If the bulb fails to light when the ignition switch is turned on, disconnect the wire from the pressure switch.
2. Check for continuity between the switch terminal and the switch body. If resistance is noted, or if there is no continuity, the switch is defective. If there is continuity (no resistance), check the bulb and wiring.

Checking the oil pressure indicator switch

3. The warning bulb should go off when the engine passes 1,500 rpm. If it does not, stop the engine and disconnect the switch lead. Connect an ohmmeter or continuity light between the switch lead and the engine (ground). There should be no resistance when the engine is off, and infinite resistance (no continuity) when rpm is above 1,500.
4. If continuity is noted with the engine turning over 1,500 rpm, check oil pressure. If oil pressure is satisfactory, replace the indicator switch. Use thread locking compound when installing the switch. Tighten it to 10.0–11.5 ft lbs.

FUEL SYSTEM

Refer to "Carburetors" in the "General Information" section for carburetor theory, inspection, and troubleshooting.

GAS TANK

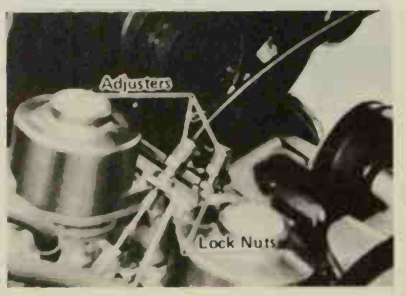
Removal

1. Turn off the fuel petcock. Slide the fuel line clamps off the petcock fitting, and disconnect the two fuel lines from the petcock.
2. Open the seat. Unhook the rubber tank strap, and pull the tank backward and off the machine.

Installation

1. Installation is the reverse of removal.
2. Secure all fuel line connections. Check for leaks before operation.

CARBURETORS



Removal

The carburetors are removed together.
1. Remove the gas tank.
2. Remove the left and right sidecovers.
3. Loosen the rubber intake manifold clamp screws and the air cleaner duct clamp screws and move the duct clamps away from the carburetors.
4. Pull the carburetors out of the intake manifolds and move them as far as possible to the right-side of the motorcycle.

Loosening the carburetor clamp screws

5. Adjust the cable adjusters at the twist-grip to yield the maximum amount of throttle cable free-play. Unscrew each of the cable adjusters at the carburetors from its bracket and disengage each throttle cable from the pulley.
6. Remove the carburetors from the machine, taking care to pull the overflow and breather tubes out of their guide.

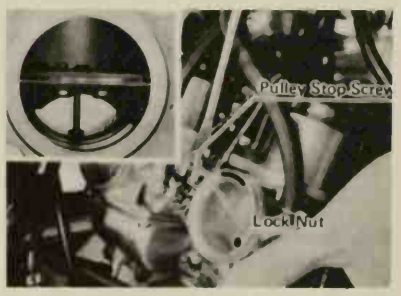
Cable adjusters are detached from their brackets to remove carburetors

Disassembly

1. Drain the fuel from each float bowl. Although not necessary for disassembly, the carbs may be removed from their mounting plate by removing the two screws which secure each one, and disconnecting the choke linkage and balance screw connection.
2. Remove the carburetor caps. Pull out the throttle slide and remove the slide gasket. To remove the needle, remove the retaining screw.

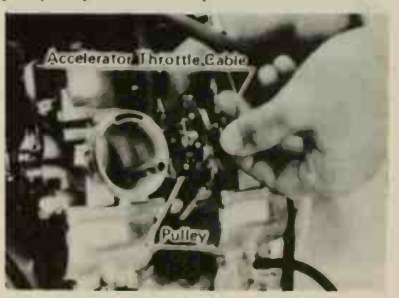
Removing the main jet and keeper spring

3. Remove the screw securing the cover plate made accessible by removal of the slide. Unscrew and remove the main and slow air jets.
4. Remove the float bowl screws, and take off the float bowl.
5. Lift out the jet keeper spring. Push out the float pivot pin. Remove the float and float needle.
6. Unscrew the float needle seat retainer, and pull out the seat.
7. Pull out the main jet. Turn the carb right side up and allow the needle jet to drop out.
8. Unscrew and remove the starter jet. Remove the pilot passage plug, and unscrew the pilot jet and slow jet.



Assembly

1. Reverse the disassembly procedure. Use new gaskets and O-rings.



Installation

1. Check that the butterfly valves are parallel to the carburetor bores when the pulley is rotated fully. If not, loosen the pulley stop screw locknut and turn the screw to make the adjustment. Tighten the locknut.
2. Engage the accelerator throttle cable with the pulley, and screw the cable adjuster all the way into its bracket. Install the decelerator cable in the same manner. Screw both cable adjusters out about halfway of their length.
3. The remainder of the procedure is the reverse of removal. Be sure that all lines are correctly routed and properly secured. Adjust the throttle cables.

Check for proper operation before riding the machine.

Use the pulley stop screw, if necessary, so that the butterfly valves are parallel to their bores when the pulley is opened as far as possible

Attaching the accelerator cable to the pulley

Carburetor Specifications

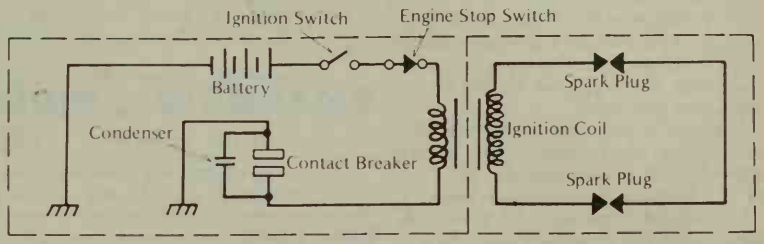
Type	CVB36
Main jet	125
Main air jet	60
Slow air jet	90
Pilot jet	35
Pilot screw (turns out)	1¼ ± 1¾
Fuel level (mm/in.)	33.5/1.32
Butterfly angle	10° 30′

ELECTRICAL SYSTEMS

IGNITION SYSTEM

1. The ignition system consists of a single set of points, a condenser, and the ignition coil. The coil has two leads—one for each plug—and the cylinders therefore fire at the same time. However, since only one cylinder is on the compression stroke at any time, there is a waste spark at the other cylinder.

2. Since the two plug leads are interdependent (one connected to each end of the secondary coil), disconnecting one lead will result in a lack of spark at both cylinders. Therefore, if one plug is dirty, fouled, or defective, neither cylinder will have spark.



3. If there is no spark, and common items such as fuse, plugs, points, and wiring connections have been checked, remove the plug caps and check for spark by grounding the leads against the cylinder head. If there is spark, one or both of the caps is defective. Replace both.

4. Check the condenser. If the proper test equipment is available, the condenser should rate 0.22 mfd. Alternately, check the condition of the points. Pitting, a burned-looking condition, or mounds and matching depressions are signs of arcing which is caused by a defective condenser. Replace both points and condenser if these conditions are noted.

5. Check the condition of the ignition coil primary winding by disconnecting the two primary winding leads and checking resistance across them (blue and red/yellow). Resistance should be 3.8–4.2 ohms.

6. If the primary winding is within these limits, check the secondary winding by measuring resistance across the two spark plug leads. It should be approximately 13K ohms.

7. If either of these tests indicates a resistance not within the given specifications, replace the coil.

Ignition circuit wiring

CHARGING SYSTEM

The charging system consists of the alternator, rectifier, and regulator.

Alternator

1. Before carrying out the following alternator output test, be sure that the battery is fully charged. A low or defective battery will cause misleading readings. If the battery will not hold a full charge, replace it.

2. Remove the left sidecover and the headlight. Disconnect the 6-wire connector beneath the sidecover and the 9-wire connector in the headlight shell. Disconnect the white rectifier lead from the battery positive lead.

3. Set a DC voltmeter to the 30v range. Connect the positive meter lead to the rectifier white lead and the negative meter lead to ground on the frame.

4. Remove the right sidecover. Disconnect the green and the brown regulator leads from terminals "F" and "I." Connect these two leads together.

NOTE: *Carry out the test as quickly as possible and disconnect the green and brown leads from each other as soon as the test is finished. Be sure that the leads are insulated from the frame.*

5. Start the engine and allow it to idle at 1,100–1,300 rpm. The voltmeter should read 14v DC or more. If less than this amount, either the alternator or the rectifier is defective.

CAUTION: *Do not let the engine turn above idle speed or the electrical components may be damaged.*

6. If the proper voltage reading was not obtained, check the rectifier as outlined in the following procedure. If the rectifier is satisfactory, check the alternator current output as follows.

7. Connect a 1 ohm-200W variable resistor, one lead to the rectifier white lead and the other to ground on the frame. Set the resistor at its maximum resistance and start the engine. Adjust the resistor to maintain a voltmeter reading of 14.5v, while gradually raising rpm to 5,000.

8. Stop the engine. Disconnect the voltmeter and the resistor lead to the rectifier white wire.

9. Connect an ammeter, set to the 30a DC range, to the variable resistor and to the rectifier white wire. This will put the meter, resistor, and rectifier in series. Be sure that all connections are tight. Start and run the engine at 5,000 rpm. The meter should read 13a DC. If the current reading is lower, the alternator is defective.

To determine which alternator component is faulty, proceed as follows:

10. Remove the right sidecover and disconnect the plug just below the regulator. With an ohmmeter, check the resistance between each of the three leads. Resistance should be 0.4–0.6 ohms. If any measurement shows infinite resistance, the armature has an open circuit and must be replaced.

11. With the highest meter range set to operate, measure resistance between each of the three leads and the frame (ground). Resistance should be infinite in each case. If a reading less than this is noted, the armature must be replaced as there is a short circuit.

12. Using the low range on the ohmmeter, check resistance between the field coil leads: green and black. It must be 4.8 ohms. An infinite reading indicates a break in the field coil, while a lower one indicates a short. In either case, replace the coil.

Rectifier

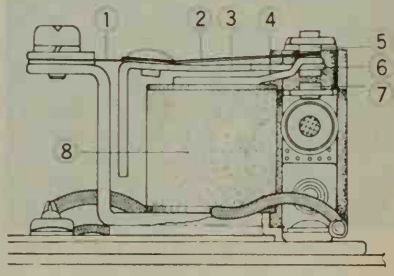
1. A full-wave rectifier with six diodes is used. An ohmmeter is used to check the rectifier.

2. Remove the left sidecover, disconnect the white rectifier lead from the battery and disconnect the rectifier black lead. The engine must be off.

3. Remove the right sidecover and disconnect the plug below the regulator.

4. Using the 10 or 100 ohm meter range, check resistance between the white lead and each yellow lead in turn, and then between the black lead and each yellow lead. Resistance measurements must be taken in both directions: that is, reverse the meter probes after each reading and take another.

Note the readings. If there is low resistance in one direction, there must be 10 times the amount when the leads are reversed. If any set of readings are either low or high in both directions, the rectifier must be replaced.



Regulator

1. Remove the left sidecover and disconnect the 6-wire connector. Remove the headlight and disconnect the 9-wire connector in the shell.

2. Set a voltmeter to the 30v DC range and connect it across the battery. Start the engine and run it at 1,600 rpm. The meter should read 14–15v.

NOTE: *As in the alternator test, the battery must be fully charged.*

3. Increase engine speed. At 4,000 rpm, the meter reading should again be 14–15v.

1. Spring
2. Spring
3. Armature
4. Adjuster arm
5. Point P_1
6. Point P_0
7. Point P_2
8. Relay coil

Voltage regulator components

NOTE: *Proceed to 4,000 rpm from a starting point of 1,600. If rpm returns to idle speed, increase it gradually to 1,600 and then to 4,000.*

4. If voltage was not correct in both cases, proceed with the following checks:

NOTE: *If the machine is still under warranty, the regulator should be replaced at this point.*

5. Remove the right sidecover; disconnect the black, green, and brown regulator leads from terminals "E," "F," and "I." Remove the regulator cover.

6. With the ohmmeter set to the low range, check the resistance according to the chart:

Regulator Resistance

Terminal	Point P_o	Resistance	Results
F—I	Position 1①	0 Ω	If more than 0 Ω, points P_o and P_1 are dirty or fouled.
	Position 2②	about 9 Ω	If no reading, resistor Rf is open. If no resistance, there is a short. Replace regulator.
F—E	Position 1①	about 100 Ω	If no reading, the relay coil is open. If no resistance, there is a short. Replace regulator.
	Position 2②	0 Ω	If more than 0 Ω, points P_o and P_1 are dirty or fouled.

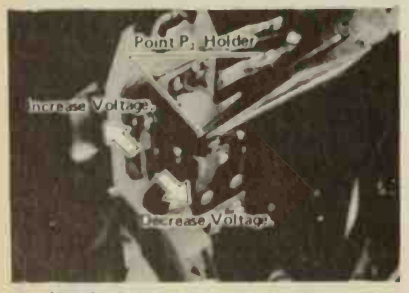
① Points P_o and P_1 are in contact by spring force.
② Points P_o and P_1 are in contract by pressing on the armature with a finger.

7. Clean points with solvent if necessary. If badly pitted, use emery cloth. If the points cannot be cleaned to achieve zero ohms resistance, replace the regulator.

8. Press down on the armature and check the gap. It should be 0.3 mm (0.012 in.). If not correct, bend the P_2 holder.

9. Check the gap between P and P_0. It should be 0.30–0.45 mm (0.012–0.018 in.). If adjustment is needed, bend the holder for P_1.

10. Assemble the regulator and make all connections. Recheck regulator output as described previously. If voltage was too high, or too low, adjust be bending the adjusting arm. Bending the arm out away from the machine will increase the output voltage and vice versa.



11. Recheck output. At 2,000 rpm, output should be 14–15v. Adjust again, if necessary as in Step 10.

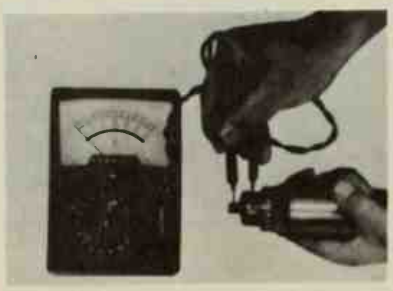
12. Check output at 4,000 rpm. If voltage was too high or too low, bend the P_2 holder. Bend it toward the machine to increase voltage, and vice versa.

13. Recheck at 2,000 and 4,000 rpm.

Bending the adjuster arm to correct regulator output

Bending the P_2 holder to correct regulator output

STARTER MOTOR



1. Refer to "Engine and Transmission" for removal and installation procedures. See "Left Crankcase Cover Components, Alternator, and Starter Assembly."

2. Disassemble the starter motor by removing the body screws.

3. Carbon brush length is 11.0–12.5 mm (0.4–0.5 in.) new. Serviceable limit is 6.0 mm (0.24 in.).

4. Clean the commutator surface with a solvent, polishing with fine emery cloth if necessary.

5. Clean out the commutator grooves and check their condition. Standard groove depth is 0.5–0.8 mm (0.02–0.03 in.), while the serviceable limit is 0.2 mm (0.008 in.).

Checking the starter motor armature for continuity between segments

6. There must be little or no resistance between each of the commutator segments. Use low meter range when checking. Resistance between the segments and the armature shaft must be infinite. Use high range when checking.

7. Check resistance between the positive carbon brush and the starter motor lead. There must be no or very little resistance. If considerable resistance is noted, the field coils must be replaced. Use the lowest meter range when making this check.

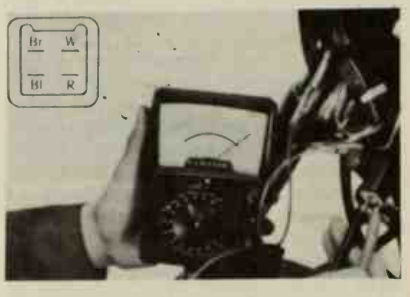
8. Check resistance between the positive carbon brush and the starter motor body. It must be infinite, or there is a short necessitating replacement of the field coils. Use the highest meter range when making this check.

Solenoid

1. After disconnecting the motor lead from the solenoid, connect an ohmmeter, set on the low scale, across the solenoid terminals. Push the starter button. Resistance when the button is pushed must be zero. If higher, replace the solenoid.

2. If the solenoid does not click when the starter button is pushed, disconnect the black and yellow/red solenoid leads and check resistance across the terminals. It must be close to zero ohms. If higher, replace the solenoid.

3. Check that voltage is getting to the solenoid from the battery. If so, replace the solenoid if it failed any of the above tests.



SWITCHES

Igntition Switch

1. In the "Off" position, all four switch leads must be insulated (no continuity) from each other.

2. In the "On" position, there must be continuity between the white and brown leads and between the blue and red leads.

3. In the "Park" position, there must be continuity between the white and red leads; none between the others.

Checking ignition switch operation

Headlight Dimmer Switch

1. In the "high beam" position, there must be continuity between the blue and red/black leads.

2. In the "low beam" position there must be continuity between the red/yellow and blue leads.

Brake Light Switches

DISC BRAKE

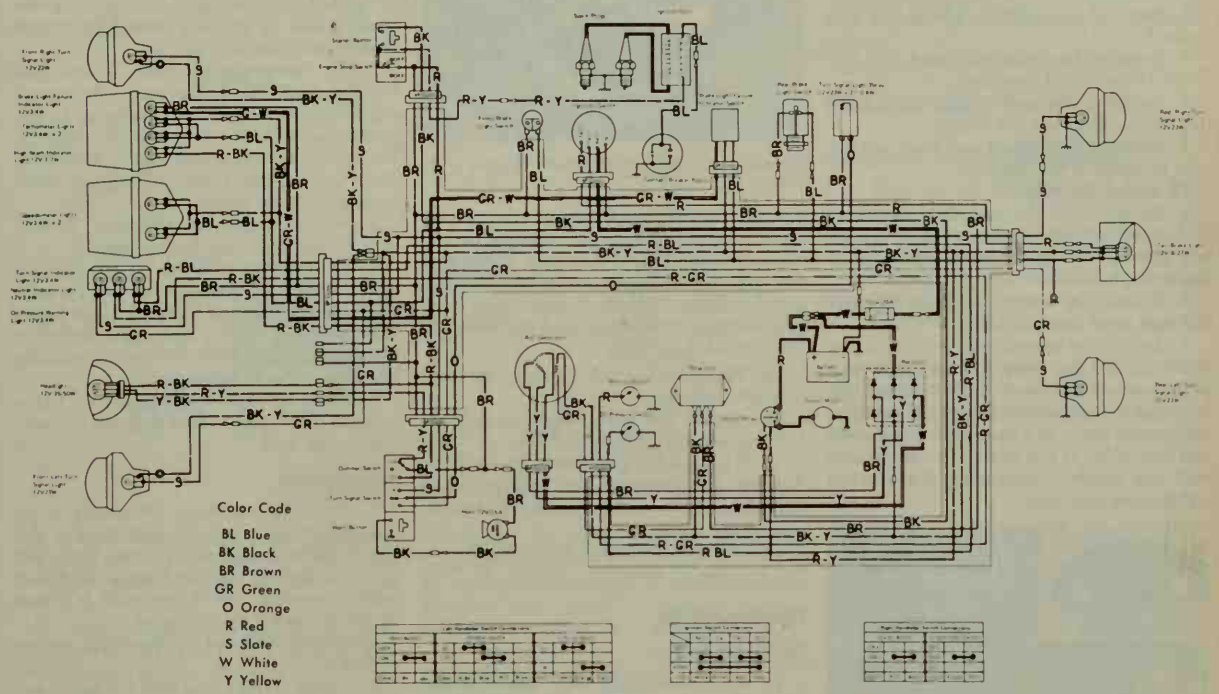
1. Disconnect the leads from the switch which is just above the lower triple clamp. Continuity should exist when the brake lever is pulled. If not, replace the switch.

2. Protect plated or painted surfaces from possible brake fluid spillage when removing the switch.

3. Apply thread locking compound to

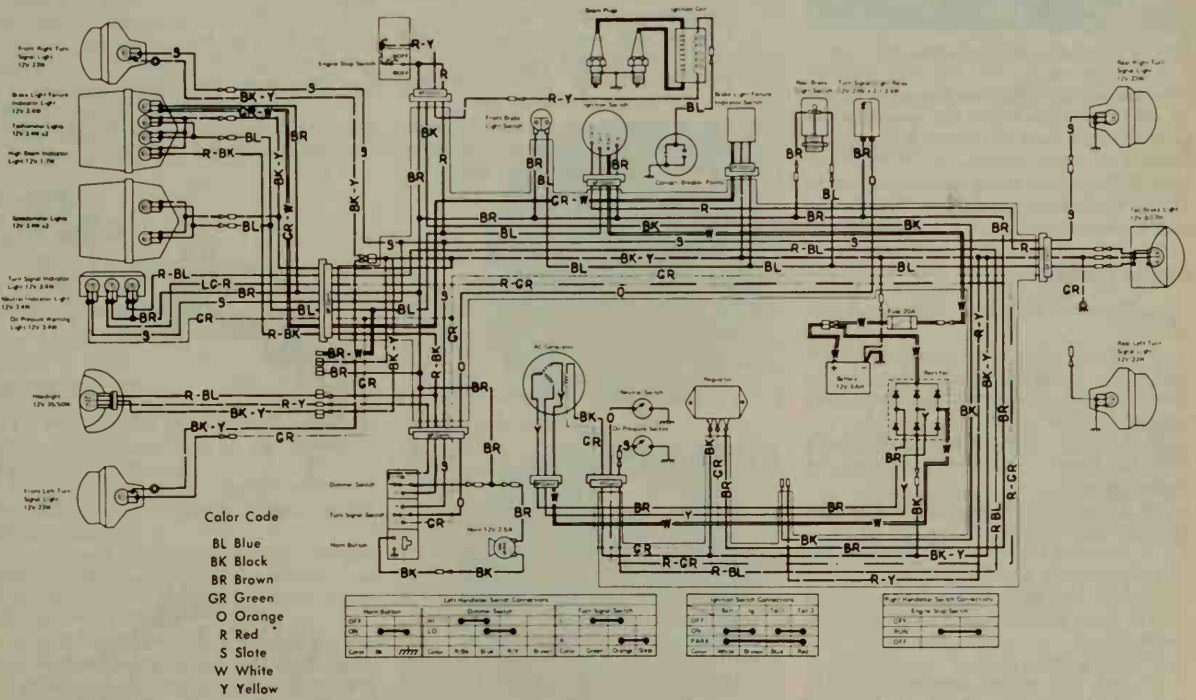
the threads of the new switch, but not on the lower quarter of the threads to avoid contamination of the brake fluid.

4. Bleed the brake lines.



DRUM BRAKE

1. Front drum brake light leads are in the headlight shell (blue and brown).



2. Rear brake light switch leads are accessible at the rear of the gask tank.

3. Continuity between the leads must be present when the brake lever or pedal is applied, or the switch must be replaced.

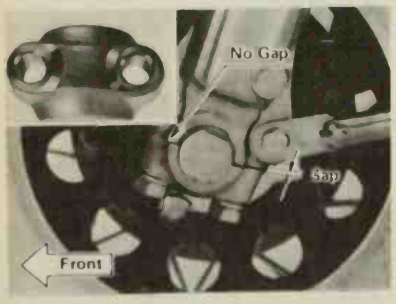
WIRING DIAGRAMS

KZ400D

KZ400S

CHASSIS

FRONT WHEEL



Removal and Installation

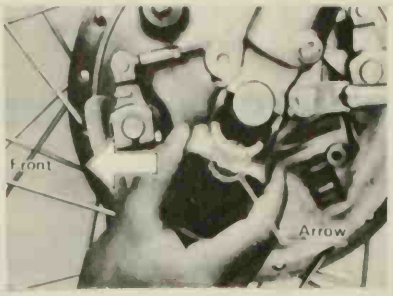
DISC BRAKE

1. Support the front wheel off the ground.
2. Remove the axle nut cotter pin. Remove the nut and washer.
3. Remove the axle clamp nuts from the slider. Remove the clamp.
4. Support the wheel and pull out the axle to remove the wheel.

To install the wheel:

5. Be sure that the speedometer cable is located on the inside of the fender bracket. Fit the speedometer gear housing to the wheel.
6. Install the wheel, slipping the axle through from the disc side.
7. Install the axle clamp. Note that the arrow on the bottom of the clamp must point toward the front of the motorcycle. The clamp is machined unevenly so that there will be a gap between the clamp and the slider at the rear of the slider. Install the washers and nuts, but do not tighten them.

Install the axle clamp as shown



8. Install and tighten the axle nut to 72–94 ft lbs. Check that the speedometer gear housing does not move when this is done. Use a new cotter pin.
9. Tighten the front axle clamp nut to 13.0–14.5 ft lbs, then tighten the rear nut to the same torque.

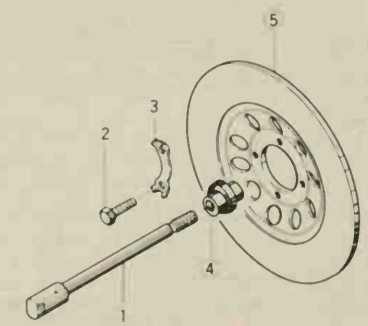
DRUM BRAKE

1. Support the front wheel off the ground.
2. Remove the brake cable cotter pin and unscrew the adjusting nut to disconnect the cable from the brake plate. Take out the brake lever fitting.
3. Disconnect the speedometer cable from the brake plate after removing the securing bolt.
4. Unbolt the brake anchor from the slider and the brake plate.
5. Remove the axle nut. Remove the axle clamp nuts and the clamp.
6. Lift the wheel slightly, and pull out the axle, then remove the wheel from the machine.

To install the wheel:

7. Put the wheel into position between the sliders. Insert the axle from the brake plate side. Install the axle clamp.

The axle clamp arrow points toward the front of the motorcycle



Install, but do not tighten, the clamp nuts. Note that the arrow stamped on the clamp points toward the front of the motorcycle. The clamp is machined unevenly. When installed, there will be a gap between the clamp and the slider at the rear of the slider.

8. Fit, but do not tighten, the axle washer and nut.
9. Install the brake anchor, tightening the nuts to 19.5–22.0 ft lbs.
10. Tighten the axle nut to 72–94 ft lbs. Tighten the forewardmost clamp nut to 13.0–14.5 ft lbs, and then tighten the rear one to the same torque.
11. The remainder of the procedure is the reverse of removal.

Disassembly

DISC BRAKE

1. To disassemble the speedometer gear housing, disconnect the cable. Pull out the gear drive with snap-ring pliers. Remove the bush and pinion after drilling out the locating pin. Pack the assembly with grease prior to assembly.
2. Unbolt and remove the disc. Remove the disc-side hub cap.
3. Pry out the disc side grease seal. Remove the bearing retainer circlip.
4. Using a drift, tap around the outer race of the speedometer gear side wheel bearing until the disc side bearing is driven out.

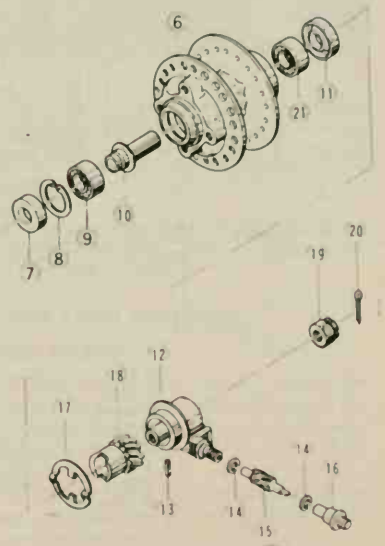
1. Axle
2. Bolt
3. Lockplate
4. Cap
5. Brake disc
6. Wheel hub
7. Grease seal
8. Circlip
9. Wheel bearing
10. Spacer
11. Grease seal
12. Speedometer gear housing
13. Pin
14. Washer
15. Speedometer pinion
16. Bush
17. Gear drive
18. Speedometer gear
19. Axle nut
20. Cotter pin
21. Wheel bearing

5. Remove the remaining grease seal and speedometer drive. Remove the remaining wheel bearing by tapping out from the inside.

DRUM BRAKE

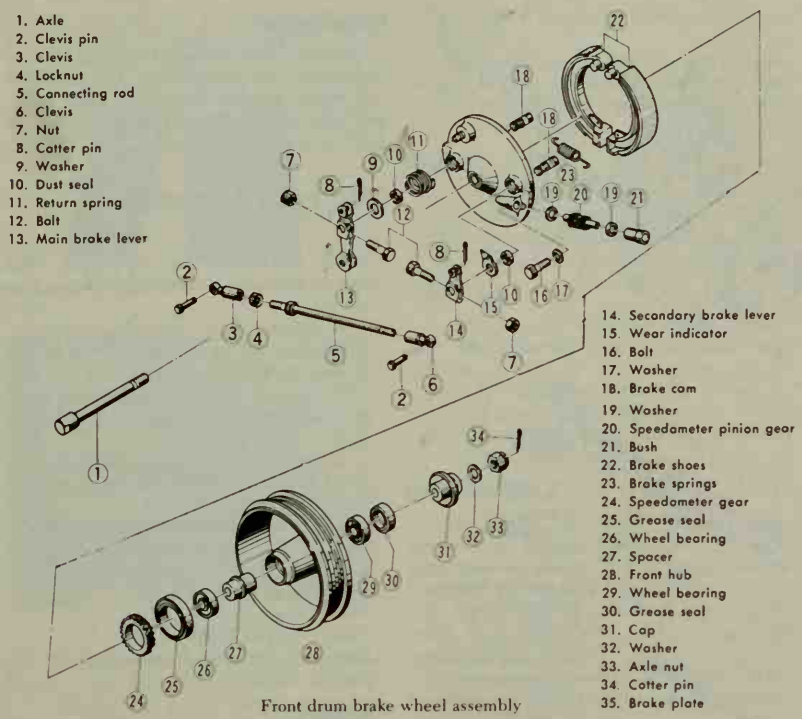
1. Remove the brake linings from the brake plate by pulling them apart until free of their cams.
2. To remove the brake levers and linkage from the brake cams, first mark the positions of the levers relative to the cams. Remove the pinch-bolts. Remove the levers, return spring, wear indicator, etc. Push the cams out of the brake plate noting the dust seals.
3. Remove the speedometer pinion gear by unscrewing the bushing.
4. Remove the hub cap (axle nut side).
5. Pry out the grease seal. With a suitable drift, tap around the race of the right-side wheel bearing until the left-side bearing is free. Remove the remaining bearing in the same manner.
6. Remove the speedometer gear using a gear puller. Remove the remaining grease seal.

Inspection



1. Axle run-out (max. standard) is 0.1 mm (0.004 in.). Serviceable limit is 0.2 mm (0.008 in.). Although it may be possible to straighten slightly bent axles, those with a run-out which exceeds 0.7 mm (0.028 in.) must be replaced.

Measured run-out is the total gauge variation.



2. Check wheel bearings for rough rotation, binding, looseness, etc., after removing old grease and oiling lightly.
3. Grease seals which have been removed must be replaced with new ones.

If the seals are still in place, check for obvious damage, hardening, etc.

4. For brake disc inspection, refer to the "Disc Brake" section, following.
5. Check brake lining thickness. Standard is 4.75–5.20 mm (0.19–0.20 in.). Serviceable limit is 2.5 mm (0.10 in.).

Front disc brake wheel assembly

Front drum brake wheel assembly

6. Check brake drum inside diameter. Standard is 180.0–180.2 mm (7.086–7.094 in.). Serviceable limit is 180.75 mm (7.116 in.).

7. Check brake spring free-length. Standard is 46.7–47.3 mm (1.84–1.86 in.). Serviceable limit is 48.5 mm (1.91 in.).

8. Brake cam diameter (standard) is 14.957–14.984 mm (0.5889–0.5899 in.). Serviceable limit is 14.83 mm (0.584 in.). Cam hole diameter is 15.000–15.027 mm (0.5906–0.5916 in.). Serviceable limit is 15.18 mm (0.598 in.).

9. Wheel bearing numbers are as follows:

Disc brake: #6302
Drum brake:
left #6302Z
right #6302

Assembly

DISC BRAKE

1. Pack bearings before assembly. Press them into place with a suitable driver. Press in new grease seals.

2. Tighten the disc bolts to 11.5–16.0 ft lbs.

DRUM BRAKE

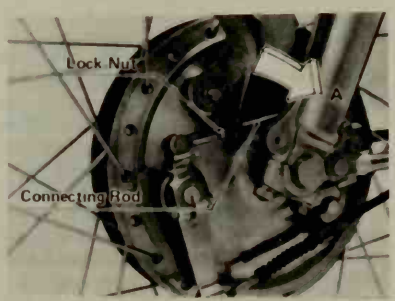
1. Grease the speedometer pinion gear, and replace it with the washers. Screw in the bushing.

2. Grease the cams lightly and install them. Grease the brake pivot pins. Install the linings.

3. Be sure to fit the dust seals to the cams. Install the brake wear indicator so that the point is just to the right of the "E" in "RANGE."

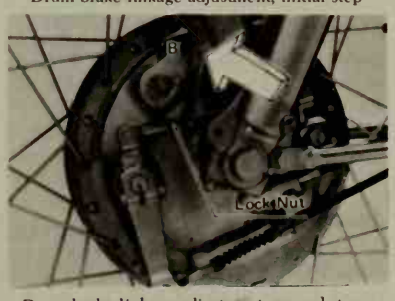
4. Fit the brake linkage, engaging the end of the return spring into its hole in the brake plate, then push on the levers aligning the reference marks made before removal.

5. Assemble the hub, packing the bearings with grease and pressing them in with a suitable drift. If the speedometer gear was removed, peen it in four places for security after pressing it on.



6. The remainder of the procedure is the reverse of disassembly.

LINKAGE ADJUSTMENT



1. Fit the wheel to the motorcycle and secure it at all points.

2. Support the front wheel off the ground.

3. Loosen the connecting rod locknut and turn the rod one turn in the direction shown.

Drum brake linkage adjustment, initial step

Drum brake linkage adjustment, second step

4. Spin the wheel slowly and turn in the cable adjusting nut until the shoe controlled by the main brake lever just touches the drum.

5. Continue turning the wheel, and turn the connecting rod in the direction "B" shown until the secondary shoe just touches the drum.

6. The brakes are now synchronized. Tighten the connecting rod locknut. Adjust the cable as outlined in "Maintenance."

REAR WHEEL

Removal and Installation

1. Disconnect the brake anchor from the brake plate.

2. Disconnect the brake light switch spring from the brake pedal. Remove the brake adjusting nut from the brake rod. Disconnect the rod from the brake lever.

3. Remove the axle nut. Take out the axle.

4. Remove the axle spacer from the right-side of the wheel. Move the wheel as far as possible to the right to detach it from the coupling and remove it from the motorcycle.

To install the wheel:

5. Reverse the removal procedure. The axle is inserted from the left-side of the wheel. Tighten the brake anchor nut to 19.5–22 ft lbs. Then tighten the axle nut to 94–116 ft lbs.

Disassembly

1. Mark the position of the lever relative to the brake cam. Remove the pinch-bolt, wear indicator, and dust seal.

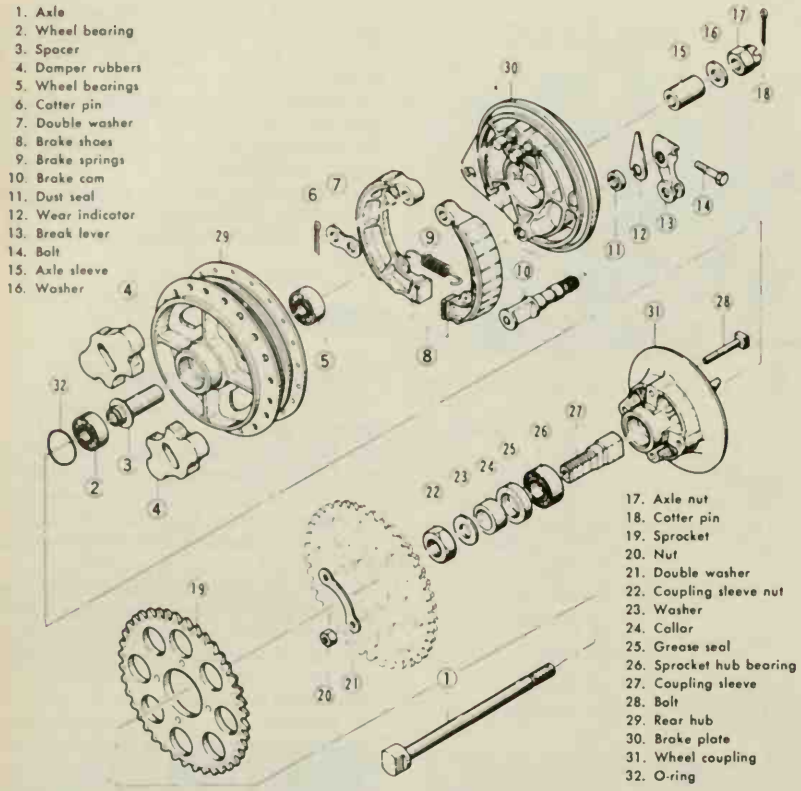
2. Remove the brake lever. Pull the brake shoes, complete with the cam, out of the brake plate. Spread the shoes to disassemble.

3. Reach through the hub with a long punch and tap out the right-side wheel bearing. Remove the spacer and tap out the left-side bearing from the inside of the hub.

Inspection

1. Axle run-out (max. standard) is 0.05 mm (0.002 in.). Serviceable limit is 0.2 mm (0.008 in.). Although it may be possible to straighten slightly bent axles, those with a run-out which exceeds 0.7 mm (0.028 in.) must be replaced.

Measured run-out is the total gauge variation.



2. Check wheel bearings for rough rotation, binding, looseness, etc., after removing old grease and oiling lightly.

3. Check brake lining thickness. Standard is 5.35–6.05 mm (0.21–0.24 in.). Serviceable limit is 2.5 mm (0.10 in.).

4. Check brake drum inside diameter. Standard is 180.0–180.2 mm (7.086–7.094 in.). Serviceable limit is 180.75 mm (7.116 in.).

5. Check brake spring free-length. Standard is 56.0 mm (2.20 in.), while serviceable limit is 58.0 mm (2.28 in.).

6. Brake cam diameter (standard) is 16.957–16.984 mm (0.6676–0.6687 in.). Serviceable limit is 16.83 mm (0.663 in.). Cam hole diameter is 17.000–17.027 mm (0.6693–0.6704 in.). Serviceable limit is

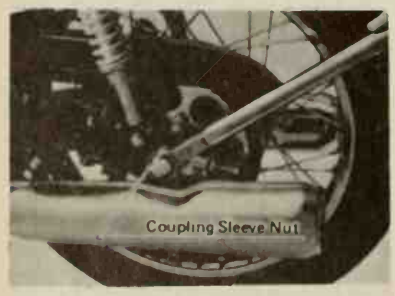
Rear wheel and sprocket assembly

17.18 mm (0.676 in.).

7. Wheel bearing numbers are as follows:

Left: #6303
Right: #6303Z

Assembly



1. Grease the cam lightly before installation. Grease the brake plate pins as well.

2. Assembly is the reverse of disassembly. When fitting the brake wear indicator, have it point just to the right of the "E" in "RANGE."

SPROCKET ASSEMBLY

Removal

1. Disconnect the drive chain. Follow the rear wheel removal procedure as previously outlined, and in addition, remove the coupling sleeve nut and washer. The wheel and sprocket assembly can then be removed from the motorcycle together.

Loosening the coupling sleeve nut

Disassembly

1. Bend down the locking tabs on the sprocket nuts. Remove the nuts and the sprocket. Detach the coupling from the rear wheel.

2. Pull out the sleeve and collar.

3. Remove the grease seal by prying it out.

4. Use a suitable drift to tap out the coupling bearing. The bearing is driven out of the sprocket side of the coupling.

Inspection

1. Check condition of the coupling rubber dampers in the wheel hub. Replace any which are damaged.

2. Check the condition of the coupling bearing in the same manner as wheel bearings. Repack with new grease before installation.

3. Check the sprocket teeth for condition. Check diameter. Standard is 217.4 mm (8.56 in.). Serviceable limit is 215.5 mm (8.48 in.).

4. Sprocket run-out is less than 0.3 mm (0.012 in.); replace the sprocket if it is warped more than 0.5 mm (0.020 in.).

5. Chain condition can be checked by stretching the chain with about 25 lbs pressure and measuring the length of a 20-pin section of chain. Standard length is 317.5 mm (12.50 in.); replace the chain if the measurement is over 323 mm (12.7 in.).

Assembly

1. Reverse the disassembly procedure. Repack the bearing with grease. Tighten sprocket nuts to 25–31 ft lbs.

Installation

Refer to "Rear Wheel Removal and Installation" for procedures. Be sure that the chain masterlink spring clip is installed with the closed end facing the direction of chain rotation.

DISC BRAKE SERVICE

When servicing the hydraulic disc brake system, observe the following precautions:

a. Brake fluid absorbs moisture. Therefore, never add fluid from an old or an unsealed container;

b. Do not add fluid which has been pumped out of the system. Add new fluid only;

c. Protect all plated and painted surfaces from possible contact with spilled brake fluid;

d. Do not mix types of brake fluid. Use DOT 3 brake fluid only. The following types are recommended:

Atlas Extra Heavy-Duty
Shell Super Heavy-Duty
Texaco Super Heavy-Duty
Wagner Lockheed Heavy-Duty
Girling Amber

Flushing

1. Attach a clear plastic hose which will fit snugly to the caliper bleed nipple and put the other end in a quantity of brake fluid in a suitable container.

2. Open the bleed nipple and apply the brake lever in slow, even strokes until all of the old fluid is pumped out.

3. Close the bleed nipple. Refill the reservoir with fresh fluid. Open the nipple, apply the lever, and, holding it against the handgrip, close the nipple and quickly release the lever.

4. Repeat this procedure until the new fluid begins to come out of the hose.

5. Bleed the air from the system.

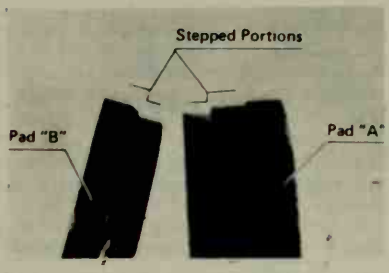
Bleeding

This should be done after flushing, or if any brake line junction has been disconnected, or if the brake lever feels spongy or the brake is inefficient.

1. Top up the fluid reservoir if necessary.

2. With the reservoir cap off, slowly pump the lever several times until no air bubbles can be seen rising from the passages at the bottom.

3. Replace the cap. Fit a length of plastic hose which will fit snugly to the caliper bleed nipple, immersing the other end of the hose in a quantity of brake fluid in a suitable container.



4. Apply the brake lever several times until it becomes hard. Hold it tightly and loosen the bleed nipple, then close it quickly.

5. Release the lever. Repeat this procedure until brake fluid only comes out of the hose, and no air bubbles.

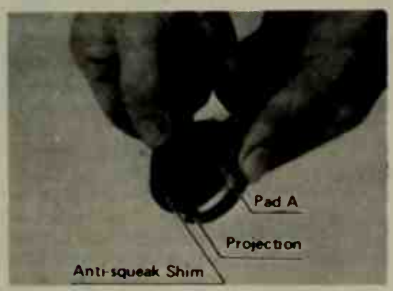
Pad Replacement

1. When either pad is worn down to the stepped portion, replace both as a set.

2. Remove the front wheel. Remove the screw from the inner caliper half, tak-

Replace pads when either is worn to the stepped portion

Removing pad B



ing off its washer and the metal plate. Remove the inner pad ("B").

3. Apply the brake lever until the outer pad ("A") is pushed out.

4. Loosen the bleed nipple slightly, push the piston in as far as possible, then tighten the nipple.

5. Place the shim on the rear of the outer pad, shim projection over pad projection, align the pad projection with the slot in the bottom of the caliper, and insert the pad.

6. Install the "B," metal disc, and screw. Use thread locking compound on the screw.

Fit the shim projection over the pad projection

7. Check reservoir fluid level.

NOTE: *After fitting new pads, avoid hard application of the brake for at least 50 miles. Replace the dust seal and piston fluid seal every other time the pads are replaced. Refer to "Caliper" for procedures.*

Disc

1. The disc may be checked in place.

2. Measure thickness. Standard is 6.95–7.05 mm (0.27–0.28 in.). Serviceable limit is 5.5 mm (0.22 in.).

3. Check run-out. Standard is 0.1 mm (0.004 in.) or less. Serviceable limit is 0.3 mm (0.012 in.).

NOTE: *If run-out is excessive, check that the reading is not being caused by bad wheel bearings before replacing the disc.*

4. The disc is easily removed by unbolting it from the wheel after the wheel is removed. Tighten the nuts to 11.5–16.0 ft lbs for installation.

Caliper

CAUTION: *Caliper parts (except disc and pads) are cleaned with new brake fluid, isopropyl alcohol, or ethyl alcohol ONLY. Do not use anything else.*

REMOVAL

1. Disconnect the brake line at the caliper and plug the end to prevent fluid spillage.

2. If the caliper holder is to be removed loosen the two allen bolts.

3. Remove the two mounting bolts and take off the caliper.

DISASSEMBLY

1. Remove the pads. Apply compressed air to the brake line fitting to force out the piston. If the piston cannot be removed, replace the caliper.

2. Being very careful of the caliper walls, remove the dust seal and the fluid seal from the caliper.

3. Remove the allen bolts previously loosened and pull out the caliper holder.

Removing the piston from the caliper with compressed air

INSPECTION

1. Check the dimensions of all parts against the specifications given in the "Chassis Specifications" chart at the end of this section.

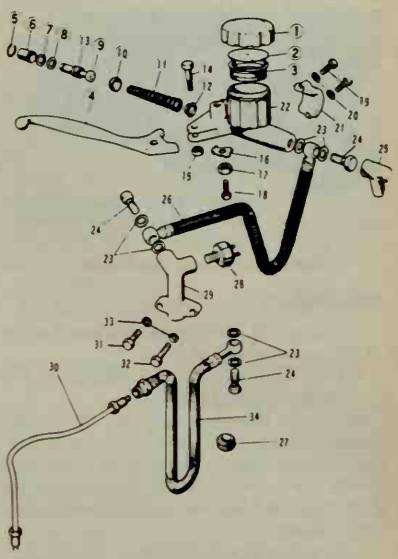
2. Replace the fluid seal if leakage around the pad is noted, if there is a large difference in wear between the pads, or if the seal is stuck to the piston.

ASSEMBLY

1. Clean caliper internals (except pads) with new brake fluid, isopropyl alcohol, or ethyl alcohol.

2. Assembly is the reverse of disassembly. Be sure that the caliper holder dust cover is properly secured. Coat the sides of the piston with brake fluid before inserting it into the caliper.

INSTALLATION



1. Installation is the reverse of removal. Tighten allen bolts to 22–26 ft lbs, and mounting bolts to 18–24 ft lbs. Tighten banjo bolts to 18–24 ft lbs.

2. Bleed the system.

Master Cylinder

REMOVAL

1. Remove the right-side mirror.

1. Cap	18. Bolt
2. Plate	19. Bolt
3. Diaphragm	20. Washer
4. Brake lever	21. Master cylinder clamp
5. Dust seal stopper	22. Master cylinder body
6. Dust seal	23. Washer
7. Retaining ring	24. Banjo bolt
8. Piston stopper	25. Dust cover
9. Piston assembly	26. Hose
10. Primary cup	27. Grommet
11. Spring assembly	28. Brake light switch
12. Check valve assembly	29. 3-way joint
13. Secondary cup	30. Pipe
14. Bolt	31. Bolt
15. Nut	32. Bolt
16. Lockwasher	33. Washer
17. Nut	34. Hose

Master cylinder assembly

2. Slip off the banjo fitting dust cover and disconnect the brake line from the master cylinder; note the washer on either side of the banjo.

3. Remove the two clamp bolts, taking care that fluid is not spilt, and remove the master cylinder.

Disassembly

1. Remove the reservoir cap and diaphragm and pour out the brake fluid.

2. Remove the brake lever. Use the special master cylinder stopper remover to remove the dust seal stopper and then take out the dust seal.

3. Remove the retaining ring and remove the stopper, piston, primary cup, spring, and check valve out of the master cylinder. Do not remove the secondary cup from the piston.

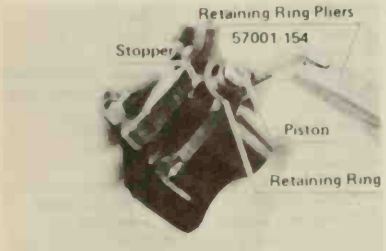
Inspection

1. Check the master cylinder components against the standard specifications given in the "Chassis Specifications" chart at the end of this section.

2. Check for obvious defects to the master cylinder bore and the piston body.

3. Inspect the rubber parts for damage or rotting and swelling. The cups should be slightly larger than the cylinder bore. If leakage at the master cylinder has occurred, replace both cups. Replacement of the secondary cup requires replacement of the piston as well.

Removing the dust seal stopper



ASSEMBLY

1. Clean all parts in new brake fluid or isopropyl or ethyl alcohol.

CAUTION: *Do not use anything else to clean brake parts.*

2. Smear the parts and the inner walls of the master cylinder with brake fluid.

3. Check that the primary cup and check valve are installed facing the right direction, and are not misaligned during installation.

Installing the retaining ring

4. Install the check valve, spring, primary cup, and piston. Fit the piston stopper.

5. Install a new retaining ring, ensuring that it is properly seated in its groove. Install the dust seal and stopper.

6. The remainder of the procedure is the reverse of disassembly.

INSTALLATION

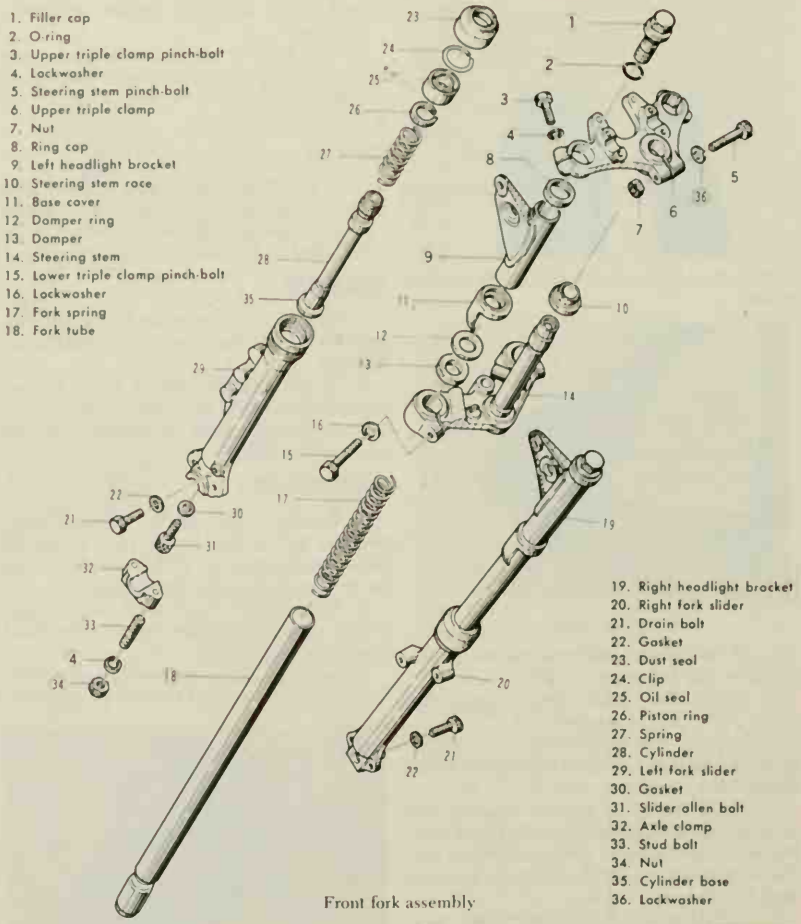
1. When installing the master cylinder, note that the small projection on the clamp goes on the twist-grip side.

2. Tighten the upper bolt first to 4.3–6.5 ft lbs, then the lower bolt to the same torque. Tighten the banjo bolt to 18–24 ft lbs and bleed the system.

FRONT FORKS

Removal

1. Remove the front wheel. Remove the fender.



2. On disc brake models, unbolt the caliper, supporting it out of the way to avoid bending the pipe.

3. If disassembly of the fork leg is required, loosen the filler cap(s) at this point.

4. Loosen the upper and lower triple clamp pinch-bolts.

5. Pull out the fork leg twisting it as necessary until it is free of the triple clamps.

6. Remove the remaining fork leg in the same manner.

Front fork assembly

Disassembly

1. Remove the filler cap and take out the fork spring. Pour the fork oil out, pumping the slider to remove it all.

2. Pry up the dust seal from the top of the slider.

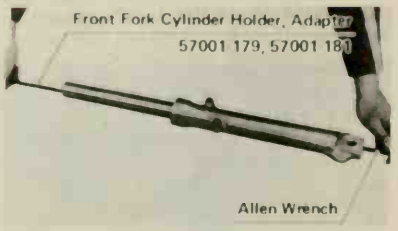
3. Insert the special piston holder to secure the cylinder and remove the allen bolt from the bottom of the slider. It may be possible to remove the allen bolt without the tool, but if the cylinder assembly begins to turn as the bolt is loosened, the tool will be necessary.

4. Pull the fork slider from the fork tube. Remove the cylinder components from the top of the fork tube.

5. Remove the slider oil seal clip and pull out the oil seal. Remove the cylinder base from the slider.

Inspection

1. Check spring free-length. Standard is 475 mm (18.7 in.). If either spring is compressed below 465 mm (18.3 in.), both springs should be replaced to ensure equal damping characteristics.



2. Check damper components for wear. Replace as necessary.

Assembly

1. Use new fork slider oil seals.

2. Install the cylinder base in the slider.

3. Press a new oil seal into the slider after lubricating the seal's outer side to facilitate assembly. Install the clip.

Removing the slider allen bolt with the special tool

4. Install the cylinder assembly in the fork tube inserting it so that the end protrudes from the bottom of the fork tube.

5. Oil the inner lips of the slider seal, fit the bottom of the cylinder into the cylinder base, sliding the slider all the way onto the fork tube.

6. Use thread locking compound on the allen bolt and tighten it.

7. Install the slider dust seal. Refill the forks with the correct grade and quantity of oil (refer to "Maintenance"). Fit the spring (close coils toward the top of the fork) and the filler cap.

Installation

1. Install the fork leg into the triple clamps until the edge of the top of the tube is flush with the upper triple clamp surface.

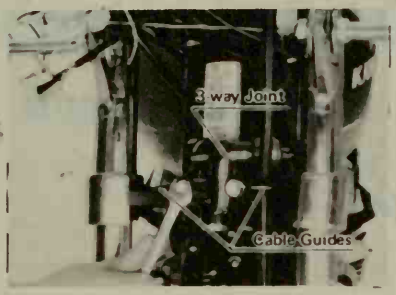
2. Tighten the upper triple clamp pinch-bolt to 11.5–13.0 ft lbs, and then the lower triple clamp pinch-bolt to 14.5–22.0 ft lbs.

3. Tighten the filler cap to 18–22 ft lbs.
4. Install the disc brake caliper, if fitted, tightening the mounting bolts to 19–23 ft lbs.
5. The remainder of the procedure is the reverse of removal.

STEERING STEM ASSEMBLY

Bearing Adjustment

1. To check bearing adjustment, support the front wheel off the ground. Grasp the lower ends of the fork sliders and push and pull them back and forth. No movement should be noted. If there is, the bearings are too loose.
2. Move the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the bearings are either too tightly adjusted, or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If noise is noted, the bearings are damaged or some are missing.



Adjusting the steering head bearings

3. With the front end off the ground, release the forks from a position several degrees off the centerline of the motorcycle. The forks should fall to either side when this is done. If they do not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some are missing.
4. To adjust the steering stem bearings, support the front wheel off the ground, loosen the steering stem bolt and the pinch-bolt. Use the special wrench to tighten or loosen the steering stem locknut (just under the upper triple clamp), until bearing action conforms to those standards in Steps 1–3.
5. Tighten the steering stem nut to 40 ft lbs. Tighten the pinch-bolt to 11.5–13.0 ft lbs. Momentarily loosen the lower triple clamp pinch-bolts, and then tighten them to 14.5–22.0 ft lbs. Recheck bearing adjustment. If proper adjustment is not possible, the bearings and races may be worn and in need of replacement.

Removal

1. Drain the disc brake fluid, if applicable.
2. Remove the front wheel. Unbolt the master cylinder from the handlebar, disconnecting the brake line from the joint on the lower triple clamp.
3. Remove the caliper and the lower brake hose.
4. Remove the front fender. Remove the forks.

Removing the disc brake joint

5. Disconnect the tach cable from the tach. Disconnect the brake light switch leads from the switch on disc brake models.
6. Remove the disc brake hose joint from the lower triple clamp.
7. Take the headlight out of the shell and disconnect the leads. Disconnect the turn signal and wiring harness leads in the headlight shell. Remove the shell.
8. Hold the instrument panel, remove the two securing nuts and remove the unit.
9. Remove the steering stem nut. Loosen the upper triple clamp pinch-bolt. Tap the underside of the triple clamp with a plastic mallet until the headlight brackets, complete with turn signals, can be removed. Continue tapping the triple clamp until it can be freed from the steering stem and hung to one side.
10. Hold the steering stem assembly in place, and unscrew and remove the steering stem locknut. When the nut is removed, lower the steering stem from the frame lug. Watch the balls in the lower race as they will fall out as the stem is lowered. The upper balls are accessible after removing the cap.

Inspection

1. The bearing balls are standard ¼ in. in size, and 19 are used in each race.
2. Clean balls in solvent. Wipe old grease off races. Check the balls for rust, dents, pitting, and other damage. Check that the race surfaces are perfectly smooth and without dents, cracks, or ripples.
3. If any parts are damaged, replace bearings and races as a set.
4. Remove races from the frame by punching them out. Drive new races straight in.
5. Remove the steering stem race, if necessary, with a hammer and punch. The race is pressed onto the stem.

Installation

1. Lubricate the races with bearing grease and press 19 balls into the frame race and the steering stem race. Raise the stem carefully into position and screw on the stem locknut.
2. The remainder of installation is the reverse of removal. When fitting the headlight brackets, note that the ring cap goes on the top and the damper, damper ring, and stem base cover are at the bottom.

SHOCK ABSORBERS

Removal

1. To remove one of the shock absorbers, remove the grab bar mounting nuts, loosen the top shock nuts, and remove the grab bar. Lifting up the rear wheel to avoid damage to the shock bolt threads, remove the lower shock bolt. Remove the capnut and washers and remove the shock absorber.
2. To remove the other shock, repeat the procedure.

Inspection

1. Check for damping by compressing the shock absorber as much as possible, then releasing. If the shock springs quickly back to full length, the damping unit is defective.

Replace shocks in pairs even if only one is bad.

2. Shock absorber dampers are sealed units and cannot be disassembled.

Installation

1. Reverse the removal procedure. Mounting point torque is 19.5–24.0 ft lbs for both upper and lower mounts.

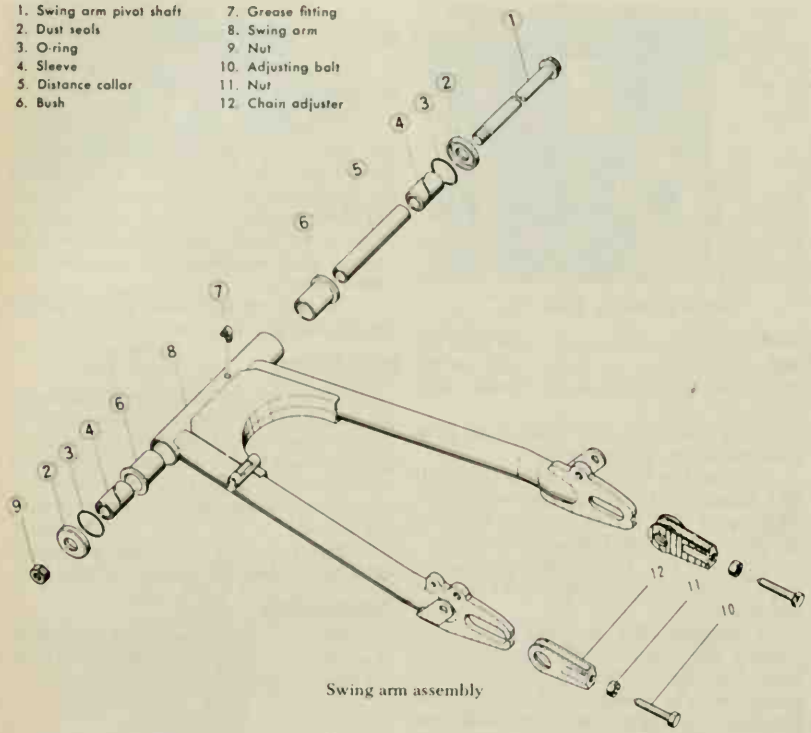
SWING ARM

Inspection

1. Remove the rear wheel, sprocket assembly, and shock absorbers.
2. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.
3. Check that the rear wheel mounting plates are parallel.
4. Grasp the swing arm and attempt to move it from side to side. Any noticeable side play indicates worn bushings which will need replacement.

Removal

1. Proceed as above (Step 1).
2. Remove the swing arm pivot shaft nut and pull out the shaft. Remove the swing arm noting the dust cap on each end which will come off.
3. Remove the chain guard and brake anchor from the swing arm.



Disassembly

1. Pull out the sleeve from each side of the swing arm. Remove the distance collar.
2. Measure bush inside diameter. Tap out the bush from each side, if worn. If bushes are removed, they must be replaced with new ones.

Inspection

1. Measure the outside diameter of the sleeves. Standard is 21.979–22.000 mm (0.8653–0.8661 in.). Serviceable limit is 21.95 mm (0.864 in.). Replace sleeves as a set of either is worn.
2. Check the inside diameter of each bush. Standard is 22.030–22.063 mm (0.8673–0.8686 in.). Serviceable limit is

1. Swing arm pivot shaft
2. Dust seals
3. O-ring
4. Sleeve
5. Distance collar
6. Bush
7. Grease fitting
8. Swing arm
9. Nut
10. Adjusting bolt
11. Nut
12. Chain adjuster

Swing arm assembly

22.26 mm (0.876 in.). Replace the bushes as a set if either is worn.

3. Check pivot shaft run-out. Standard is 0.1 mm (0.004 in.) or less. Replace the shaft if run-out exceeds 0.2 mm (0.008 in.).

Assembly

1. Oil new bushes and press them into place.
2. Lubricate the sleeves with chassis grease before installation.

Installation

1. Installation is the reverse of removal. Insert the pivot shaft into the frame from the right. Ensure that the dust caps are in place. Tighten the shaft nut to 72–94 ft lbs. Check that the swing arm pivots freely.

General Torque Specifications①

GENERAL INFORMATION

SERIAL NUMBER LOCATION

In order to prevent possible confusion when purchasing parts, always refer to the engine and frame serial numbers. The frame number is stamped on the left side of the steering lug, while the engine number is behind the cylinders on the top right side of the crankcase.

Frame number location

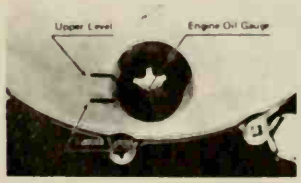
Engine number location

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in the "General Information" section.*

LUBRICATION

Motor Oil



For use in all temperatures, Kawasaki recommends SAE 20W-50 or SAE 10W-40 motor oil, service rating "SE" or "SF."

Checking Oil Level

1. Check the oil level when the engine is warm.
2. A sight glass is provided at the lower part of the clutch case. The oil level should be between the upper and lower level marks.

Changing Oil

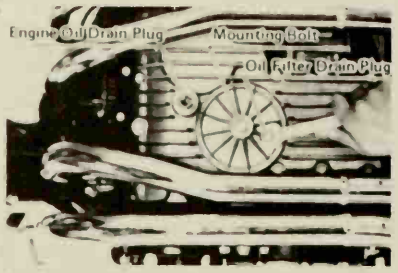
1. Change oil at 2,000 mile intervals or 60 days (summer)/30 days (winter); whichever comes first.

Oil level view window

2. Use 20W-50 or 10W-40 oil, service rated "SE" or "SF."
3. For the 900, engine oil capacity is 3.5 qts, minus filter. If oil *and* filter are being changed, capacity is 4.2 qts. For the 1000, capacities are approximately 3.2 qts minus the filter, and 3.9 qts if both oil and filter are changed.
4. Run the engine until normal operating temperature is reached, and place the motorcycle on its center stand.
5. Remove the engine and oil filter drain plugs, and allow the oil to drain into a suitable receptacle.
6. Remove the oil filter, if it is to be replaced, at this time by removing the filter mounting bolt, and dropping out the filter.
7. Rotate the engine several times, with the key off, to assure complete drainage.
8. Wipe off any metal filings which may be stuck to the magnetic drain plug, and install the plug. Intall the filter assembly, or filter drain plug only, as the case may be.
9. Torque the drain plug to 29 ft lbs (4.0 kg/m), the filter mounting bolt to 18 ft lbs (7.5 kg/m), and the filter drain plug to 16 ft lbs (2.2 kg/m).
10. Fill the engine with oil. The oil level should be between the two lines at the level window located on the right side crankcase clutch cover.
11. Check level after the engine has been running several minutes.

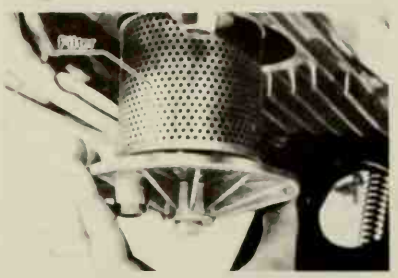
Oil Filter (Disposable)

1. A disposable cartridge oil filter is fitted, and should be changed every 4,000 miles or every other oil change.
2. When installing a new filter, make sure that the spring and both O-rings are in good condition, and replace them as necessary. The filter mounting assembly should be cleaned with clean gasoline, and blown dry, before the new filter is installed.
3. After securing the bolt to 18 ft lbs (2.5 kg/m, replenish the oil supply, and run the engine to check for any possible oil leaks.
4. Note that engine oil capacity is 4.2 qts for the 900 and 3.9 qts for the 1000 when changing this filter.

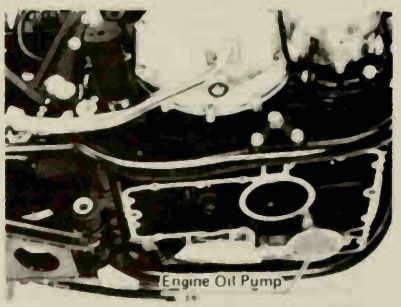


Oil Filter (Strainer)

The oil strainer is located at the oil pump pickup, and may be removed for cleaning after the oil pan is unbolted and lowered as described in the "Lubrication System" section. The strainer is secured to the pump body by 3 screws.

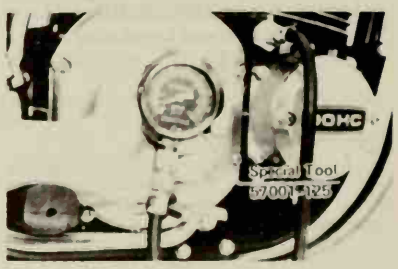


Clean the strainer in solvent, or replace it with a new one if it is damaged, then install the strainer and oil pan using a new pan gasket. After refilling the engine with oil, start the engine and check for oil leaks.



Oil Pressure

The engine oil pressure should be checked once a year, or whenever an oil pressure problem is suspected. Either the factory gauge (Part No. 57001-125), or a suitable substitute, can be connected at the oil gallery access hole at the right side of the engine after the plug has been removed. The gauge should read 2.8 lbs/in.^{2} (0.2 kg/cm^2) with the engine running at 3,000 rpm, and the engine oil temperature approximately 140° F (60° C), or operating

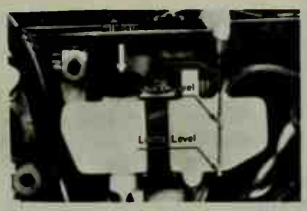


Engine and oil filter drain plug and filter mounting bolt locations

Removing the oil filter assembly

Oil pump oil filter location

Checking oil pressure



temperature. If the reading proves unsatisfactory, determine and correct the fault (restricted oil passage, clogged filter, pressure relief valve failure, etc.). Consult the "Lubrication System" section for additional information.

NOTE: *Apply Loctite® to the plug threads before installing it in the gallery access hole.*

Chain Oiler (73–74 Models)

The 73 and 74 models are equipped with a drive chain oiler, which, in conjunction with hand lubrication using a chain lubricant, is intended to keep chain wear to a minimum. The tank for the oiler is located under the seat, and has a dipstick and a filler cap. The tank should be kept filled with 30W or 40W oil.

The pump can be adjusted for oil flow. "0"

Keep the tank filled with 30 or 40W

Pump cover location

Pump output adjuster

or "1" supplies the least oil, and "5" is for maximum output. The chain should be kept wet, but not dripping.

Do not rely on the oiler to provide all the necessary chain lubrication these machines require. Every 200 miles, or more often if used in wet or dusty conditions, the chain should be hand lubricated.

Front Forks

1. The change interval is 6,000 miles or one year.

2. Recommended oil is SAE 10W or 10W20, non-detergent.

3. Fork capacities (per fork leg) are as follows:

900 (1973–75)	5.7 oz./170 cc
900 (1976)	6.5 oz./192 cc
1000 (1977–81)	5.7–6.0 oz./170–178 cc

Add an additional 0.6 oz. (15 cc) per leg if the forks have been disassembled.

4. To change the oil, remove the drain screw from the bottom of each slider and pump the slider up and down to expel the oil. Install the drain screws. Support the front wheel off the ground.

5. Loosen the upper triple clamp pinch bolts and remove the fork top bolts. Add the correct amount of oil to each fork leg.

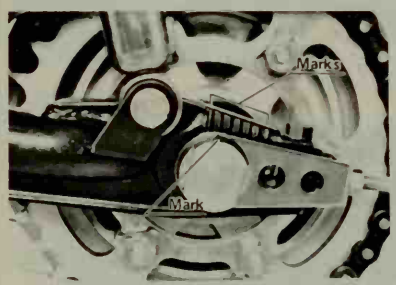
SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about 30–35 mm (1.2–1.4 in.) of total up-and-down free-play measured in the middle of the lower chain run.

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on the center stand so that the rear wheel is off the ground;



b. The transmission should be placed in neutral;

c. The chain should be clean and well-lubricated;

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably worn sprockets, which should be replaced as soon as possible.

3. To adjust the chain, first back off the rear brake adjuster nut on drum rear brakes. Loosen the brake anchor nut on disc brake models, loosen the nut on the caliper anchor.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

Rear wheel alignment marks

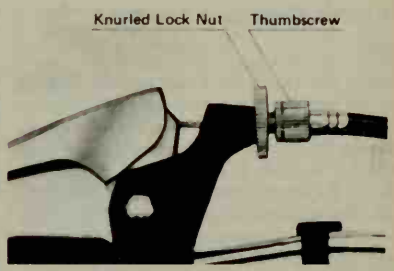
5. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately correct.

6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

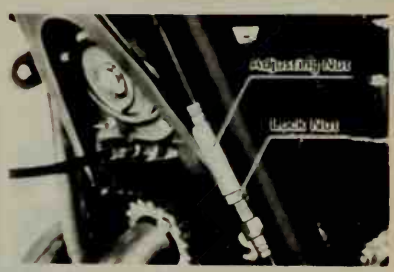
7. Tighten the axle nut and adjuster bolt nuts and check the chain tension. The chain tension should also be checked with the weight of a rider sitting on the motorcycle when it is off the center stand; the chain should still have at least ½ in. of free-play. Correct if necessary. After adjustment is correct, torque the axle nut to 72–100 ft lbs.

Fit a new cotter pin. Tighten the brake anchor nut. Readjust the rear brake on drum brake models.

NOTE: *If the engine sprocket is removed, be sure to reinstall it so that the stamped numbers face the engine. Otherwise, chain alignment will be incorrect.*



Clutch

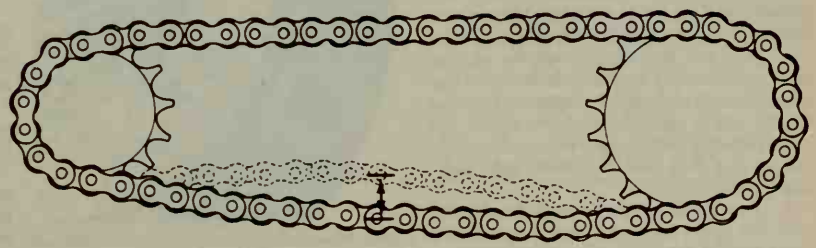


1. Loosen the knurled locknut at the hand lever, turn the thumbscrew into its seat to provide maximum cable play, then secure the locknut.

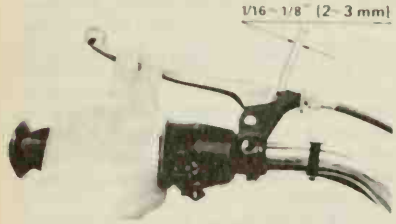
2. Loosen the locknut at the center of the cable, and screw in the adjuster to provide maximum cable play.

3. Remove the cover to gain access to the pushrod adjusting screw.

4. Loosen the locknut, and back out the adjusting screw until it turns loosely.



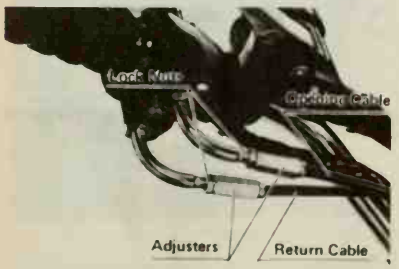
Cable adjusting points



Drain plug location

Chain slack should be measured at the middle of the lower run

5. Gently turn in the adjusting screw to the point where it suddenly becomes hard to turn, then back it out ½ turn from that point, and secure the locknut while holding the screw steady with a screwdriver.



6. Making sure that the cable sleeve ends do not catch on the edge of the cable seat, take up the cable play at the cable center until there is from 1/16–1/8 in. (2–3 mm) play at the hand lever, then secure the cable center adjuster locknut.

7. Make fine adjustments at the hand lever, if necessary, until the cable play is within its specified limits, then secure the thumbscrew locknut, and replace the oil pump cover.

Throttle Cables

900

Adjust the cables by loosening the locknut on the opening cable, and adjusting out any slack before securing the locknut again. Loosen the locknut on the closing cable, and adjust it so there is about 1/16 in. (2 mm) of play in the throttle grip, then secure the locknut. The adjustment may be varied according to personal preference and riding style, however, too tight an adjustment may cause the cables to stretch prematurely.

Always adjust the opening cable first

1000

1. There should be about 2–3 mm of throttle grip play.

2. With the throttle grip pushed completely closed, check that there is no clearance between the cable bracket and the pulley stopper.

3. If adjustment is necessary, loosen the locknuts and screw both cable adjusters in fully to give maximum throttle play.

4. Turn out the adjuster on the closing cable until there is no clearance between the cable bracket and pulley stopper when the throttle grip is pushed completely closed.

5. Turn the adjuster on the opening cable out to give 2–3 mm of throttle grip play. Tighten the locknuts.

6. If the cables cannot be properly adjusted with the upper adjusters, use those on the lower ends of the cables.

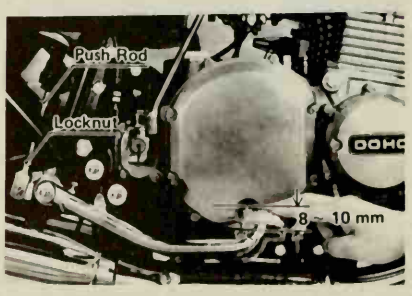
Brakes

FRONT DISC BRAKE

1. The front disc brake is automatically adjusted when in use, and therefore the condition of the brake pads should be checked periodically for wear. When either pad is worn down to the red or green limit line, the pads should be replaced.

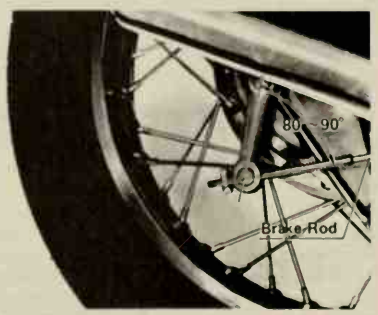
2. The brake lever is adjustable; however, the need for adjustment, other than to reduce vibration of the lever, indicates excessive wear of some of the brake components.

3. Adjust the lever by loosening the locknut, and turning the adjusting bolt a fraction of a turn so that the lever has less than 3/16 in. (5 mm) of play. Hold the adjusting bolt steady while securing the locknut, and make sure that there is still play in the lever after the locknut is tightened.



4. The brake fluid should be drained and refilled, along with a careful check of each component in the system once each year, or every 6,000 miles.

REAR DISC BRAKE



1. Check the pads periodically for wear and replace the set when they are worn to the stepped portion.

2. The brake pedal should have 8–10 mm (0.32–0.40 in.) of freeplay before the pushrod contacts the master cylinder piston. Adjust, if necessary, by loosening the pushrod locknut and turning the pushrod. Tighten the locknut and check brake operation. Readjust the brake light switch, if necessary.

3. Brake pedal position should be 20–30 mm (0.8–1.2 in.) below the top of the footpeg. If it is too high, loosen the pushrod locknut and turn the pushrod to give plenty of freeplay. Use the adjusting bolt to adjust pedal height. Tighten the pushrod locknut and check pedal freeplay.

Rear brake pedal freeplay

Correct brake rod to lever angle when the brakes are applied

REAR DRUM BRAKE

1. Check the position of the brake pedal in relation to the right front foot rest. It should be about 1/16 in. (2 mm) lower than the foot rest, and can be adjusted by loosening the adjusting bolt locknut, and rotating the bolt until the desired adjustment is attained. Be sure to secure the locknut, once a suitable adjustment is arrived at.

2. Apply the brake and note the angle formed between the actuating lever and the brake rod. If the angle is not within 80–90°, remove the lever and reposition it to correct the angle.

CAUTION: *The brake linings must be checked for wear before the lever is repositioned to avoid damage to the drum caused by worn linings. Wear indicators are fitted to late models.*

3. Make the fine adjustment by screwing in the brake rod adjusting nut until the brake pedal travel is within ¾–1¼ in. (20–30 mm) from the rest position to the fully applied position.

4. With the machine on the center stand, spin the rear wheel to check for dragging, and either readjust the brakes, or disassemble and repair the assembly to adjust for this.

NOTE: *An adjustment made with the machine on its center stand may not be the same once the machine is resting on both wheels.*

BRAKE LAMP SWITCH

The front brake lamp switch is hydraulically operated, and therefore needs no adjustment. The rear brake lamp switch is mechanical, and requires periodic adjustment to compensate for stretching of its spring, damage to the brake pedal, or to suit your preference for when the lamp comes on.

Adjust the switch by loosening the two mounting nuts, and moving the switch up or down so that the brake lamp will light after ½–¾ in. (15–20 mm) of pedal movement. Secure the locknuts when a suitable adjustment has been attained.

CAUTION: *Do not rotate the switch body itself while performing the adjustment, as this may damage the wiring.*

Rear brake light switch

Air Filter

The element should be cleaned every 3,000 miles.

To remove the filter element, open the seat, take the screen off the air cleaner, and pull the element out.

Clean the element with gasoline or some other volatile solvent, then blow it dry from the inside out with compressed air. Do not use any cleaner which will not evaporate completely.

Removing the filter element

Inspect the element and sponge gaskets for signs of wear or damage, and replace the element if either are damaged. The gaskets can be glued on if they've come loose and are still in good condition. Be careful, when installing the element, not to crimp the gaskets.

Replace the element every 6,000 miles or after 5 cleanings.

Fuel System

The fuel filter, located in the fuel tap, and the fuel lines, should be removed and cleaned at the prescribed intervals, or whenever fuel delivery problems are suspected. Simply turn the fuel tap to the stop ("S") position, and unscrew the cup to gain access to the filter. Fuel flow at both the on and reserve positions can be checked at this time.

If there is any indication of water in the gas, turn the tap to the reserve position, and allow the fuel to flow out into a suitable container until only pure gas comes out. Remove the drain plugs from the bottom of each carburetor, and drain the float bowls also.

CAUTION: *Do not start the engine until any spilled gasoline has completely evaporated, or has been wiped up. If the tap allows any gas to pass while in the stop position, the tap should be replaced, or gas may leak into the crankcase and dilute the oil.*

The sediment cup must be removed to gain access to the filter

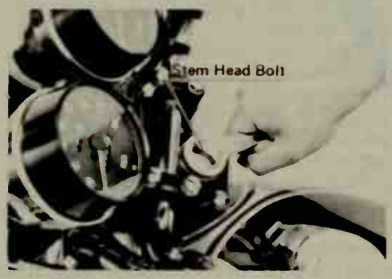
Clean the filter screen and cup, and reinstall them on the tap using a new O-ring, if necessary. Inspect the fuel lines for cracks or damage, and replace them as necessary. Straighten out any kinks or sharp bends in the lines, and make sure that the filler cap vent is not plugged, as this can interfere with normal fuel delivery.

Steering Stem Bearings

Check for proper adjustment by supporting the front wheel off the ground, grasping the fork sliders and pushing and pulling them in line with the motorcycle. No free-play should be felt. If it is, the bearings are too loosely adjusted.

Turn the forks slowly from lock-to-lock. Movement should be free, smooth, and noiseless. When released from a position a few degrees off center, the forks should fall freely to the side. If they do not, the bearings are too tightly adjusted. If the bearing movement is rough or noisy, the bearings and races are probably worn.

Adjust the bearings in the following manner:



1. Loosen the steering stem head bolt, and the clamp bolt shown in the accompanying illustration.

Loosening the steering stem rear clamp bolt

Make the adjustment slightly snug if the bearings and races have just been replaced

Tightening the lower triple clamp bolt

Periodic Maintenance Intervals ①

Daily
- Brake adjustment
- Engine oil level
- Cable adjustments
- Chain slack
- Lights and safety devices

Weekly
- Battery electrolyte level
- Spokes for tightness
- Tire pressure (cold)

Every 2000 Miles
- Change engine oil
- Clean and gap plugs
- Adjust points and check timing
- Check chain wear
- Clean fuel system

Every 3000 Miles
- Clean air filter
- General lubrication

Every 4000 Miles
- Replace oil filter
- Check valve clearance

Every 6000 Miles
- Renew brake fluid
- Change fork oil
- Replace air cleaner element

Every 12000 Miles
- Repack wheel bearings

① Based on normal usage after break-in is completed

2. Use a suitable hook spanner to turn the steering stem locknut down to tighten the steering, or up to loosen it.

Maintenance Data

	900	1000
Engine Capacity (qt/l)		
Oil change only	3.5/3.3	3.2/3.0
Oil and filter	4.2/4.0	3.9/3.7

1976: 7.1/207

Recommended Lubricants

Engine
SAE 20W-50, "SE" or "SF"
SAE 10W-40, "SE" or "SF"

Chain oiler
SAE 30W
SAE 40W

Front Forks
SAE 10W, non-detergent

Control Cables
Motor oil
Graphite-based lubricant
Molybdenum disulphide-base lubricant

Tach, Speedometer Cables
Light-duty, lithium-base grease

Wheel Bearings, Steering Stem Bearings
Waterproof, medium weight bearing grease

Grease Fittings
Waterproof, medium-weight chassis grease

Chain
SAE 90W

3. Secure the head bolt and clamp, then loosen the two lower clamp bolts to let them reseat themselves, and retighten the bolts evenly. The upper clamp bolts should be torqued to 12–13 ft lbs (1.6–1.8 kg/m), and the two lower clamp bolts should be torqued to 40–43 ft lbs (5.4–6.0 kg/m).

TUNE-UP

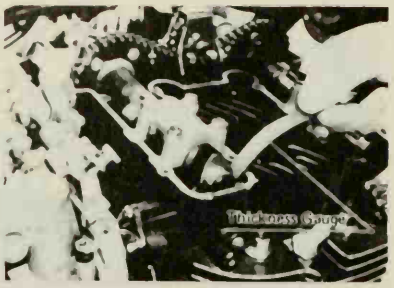
NOTE: *Common tune-up procedures are explained in detail in the "General Information" section.*

VALVE CLEARANCE

Before you start read the following:

An oil film can form between the adjusting shim and the top of the valve which can cause misleading measurements. You may find that the clearance isn't what you expected it to be after the correct shim is installed, and this film is the reason. To avoid this, do the following:

1. Measure the clearance as directed in the "Adjustment" Section.
2. Remove and measure the shim to determine what you need (i.e., if the clearance is 0.006 in., a 0.002 in. shim will result in a clearance of 0.004 in.).
3. Kick the engine through a couple dozen times with the spark plugs out and the ignition switch "Off" to remove the film, then measure the clearance again.



CAUTION: *Never rotate the engine with any of the adjusting shims removed as this may damage the cam and tappet.*

NOTE: *The type of valve tappets used in all models up to engine number Z1E-08979 have caused shim fracturing problems on some machines. If your machine is equipped with this type of tappet, consult the "Engine Disassembly, Camshafts" Section for additional information.*

Adjustment

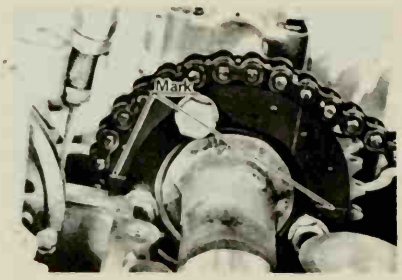
1973 MODELS

1. Open the seat all the way and remove the fuel tank, then remove the valve cover and cover gasket. Remove the spark plugs.
2. Rotate the engine so that the cam lobe (the highest portion of the cam) for the valve to be checked is pointing directly away from the valve lifter.

Be sure that the gauge is between the shim and the cam lobe

Using the special tool to remove the shim

3. Measure the clearance between the cam and the valve shim using a thickness gauge. The clearance should be within 0.002–0.004 in. (0.05–0.10 mm) for both the intake and exhaust valves. If the feeler gauge of the proper clearance will not fit between the cam and the shim, or if it slides through with little or no resistance, the clearance should be adjusted. It should be noted that some of the valves may not require adjustment. Clearance is correct if the next size thinner gauge fits easily and if the next size thicker will not fit, or fits with great resistance.
4. If the clearance is in need of adjustment, rotate the engine so that the cam lobe presses the lifter down, install the special tool (Part No. 57001-109) as illustrated, then rotate the engine so that the cam lobe points directly away from the tappet, and remove the shim.



NOTE: *The tappet is notched so that the shim can be grasped.*

5. If the valve clearance was less than 0.002 in., use a thinner shim; if the clearance was greater than 0.004 in., use a thicker shim. Shims are available in 0.05 mm increments from 2.00 mm to 3.20 mm. Consult the accompanying Valve Adjustment Chart.
6. If the valve seat is worn to the point where the smallest shim will not provide the correct clearance, check for excessive wear or burning of the valve and seat. Bring the clearance within the specified limits by removing the valve and grinding down the top of the stem slightly while holding the valve in a V-block to keep it at right angles to the side of the grinder. There must be at least 0.16 in. (4.1 mm) of stem above the valve spring collar groove.

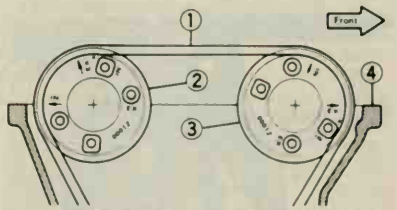
1974–78 MODELS

Marks are inscribed on the camshaft sprocket to facilitate the valve adjustment procedure.

1. Check valves when the engine is cold.
2. Remove the gas tank and valve cover. Remove the spark plugs.

Sprocket alignment marks

3. Check that the cam cap bolts are torqued to 8.8 ft lbs.
4. Working with one of the camshafts, turn the engine over until the marks on the cam sprocket align with the cylinder head mating surface.
5. Check the clearance at the two closed valves.
6. Turn the sprocket 180° until the marks align again, and check clearance at the other two valves.
7. Repeat the procedure with the other camshaft.
8. Clearance is adjusted in the same manner as outlined for 1973 models (see above), Steps 2–6.



1979 AND LATER MODELS

Check clearance as outlined above for earlier models.

Correct clearance is 0.002–0.006 in. (0.05–0.15 mm) for both intake and exhaust valves.

Be sure that the correct cam sprocket marks are used (see illustration).

When fitting new shims, be sure that the correct chart is referred to.

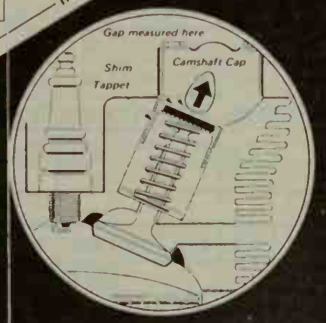
Late model cam sprockets: Cam chain (1), intake sprocket (2), exhaust sprocket (3), head mating surface (4)

CAMSHAFT CHAIN

1978 and Earlier

Wear to the chain and chain guide roller causes excessive slack in the chain which must be adjusted out periodically. Adjust the chain every 1,000 miles, or when performing a tune-up, or whenever it becomes noisy enough to warrant an adjustment. Chain noise can be heard as a rattle at an idle speed, or a high-pitched whine while running.

Cam chain adjuster



Valve Adjustment Chart (900)

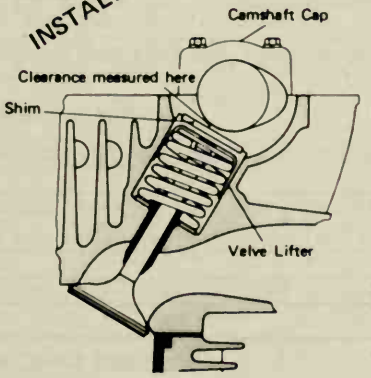
VALVE CLEARANCE

INSTALL THIS SHIM

© KAWASAKI MOTORS CORP.
1973/Printed in U.S.A.



1. To use the chart, locate the measured gap on the vertical column on the left. Find the thickness of the old shim in the top horizontal column and look down that column to find the required new shim.
2. If the valve clearance is greater than 0.10mm (.004"), use a thicker shim to correct to the specified clearance.
3. If the valve clearance is less than 0.05mm (.002"), select a thinner shim. NOTE: If there is no clearance between the shim and the cam, select a shim which is several sizes smaller and then remeasure the gap.
4. Do not put shim stock under the shim. This may cause the shim to pop out at high rpm.
5. NOTE: Check the valve clearance with the cam lobe pointing directly away from the valve, as pictured. Checking the clearance at any other cam position may result in improper valve clearance.

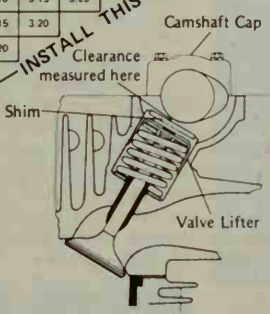
INSTALL THIS SHIM

1. Measure valve clearance (cold).
2. Check present shim size.
3. Match clearance in vertical column with present shim size in horizontal column.
4. The shim specified where the lines intersect is the one that will give you the proper clearance.

NOTES: 1. Check the valve clearance with the proper method in text (Pgs. 15 ~ 16). Checking the clearance at any other cam position may result in improper valve clearance.

2. If there is no clearance between the shim and the cam, select a shim which is several sizes smaller and then remeasure the gap.



CAUTION 1. Do not put shim stock under the shim. This may cause the shim to pop out at high rpm.

2. Do not grind the shim. This may cause it to fracture.

1. Align the sprocket mark with the cylinder head surface, and measure the clearance (cold).
2. Check present shim size.
3. Match clearance in vertical column with present shim size in horizontal column.
4. Select one of the shims specified where the lines intersect. Either shim will give you the proper clearance.

NOTE: If there is no clearance between the shim and the cam, select a shim which is several sizes smaller and then remeasure the clearance.

CAUTION
1. Do not put shim stock under the shim. This may cause the shim to pop out at high rpm, causing extensive engine damage.
2. Do not grind the shim. This may cause it to fracture, causing extensive engine damage.
3. Check the valve clearance with the proper method in the text. Checking the clearance at any other cam position may result in improper valve clearance.

Allowing the chain to go unadjusted will increase the rate of wear, cause unnecessary noise, and may lead to chain failure. When adjusting the chain no longer keeps it from making noise, either the chain is stretched out, or the guide rollers are worn out, and either or both must be replaced.

ADJUSTMENT

1. Remove the points cover. Turn the engine over a couple of times in the normal direction of rotation, then align the "T" mark for either set of pistons with the stationary timing mark.
2. Loosen the cam chain adjuster locknut and back out the adjusting bolt. Then retighten the bolt and secure the locknut.

NOTE: *When rotating the engine, turn it only in the normal direction of rotation. Do not turn it backwards if you pass the timing mark.*

1979 and Later

ADJUSTMENT

Cam chain tension is set automatically on these models. No manual adjustment is required.

CONTACT BREAKER POINTS

Breaker Point Gap Adjustment

FEELER GAUGE METHOD

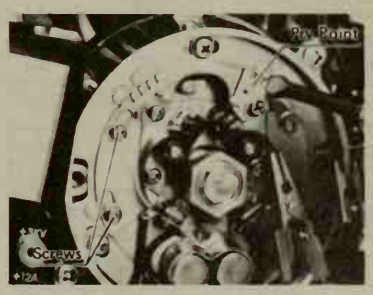
1. Rotate the crankshaft until the points set to be adjusted is at its widest opening (the highest point of the cam lobe). Check the gap using a suitable thickness gauge. If the gap is not within the specified limits of 0.012–0.016 in. (0.3–0.4 mm), loosen the screws and use a screwdriver at the pry point to increase or decrease the gap as necessary. The optimal setting is 0.014 in. (0.35 mm), and the thickness gauge should move between the points with some slight resistance; the next larger and smaller sizes should be obviously too thin and too thick respectively. Recheck the adjustment after securing the screws, and run a business card through the points to remove any dirt from the thickness gauge.
2. Rotate the engine until the other points set is at its widest position, and adjust them in the same manner.

DWELL METER METHOD

1. Although setting breaker point gaps with a feeler gauge as outlined above should produce fairly accurate results, the use of a dwell meter is even more accurate.
2. Connect the dwell meter: one lead to ground on the engine, the other lead to the points' wire terminal or spring.
3. Select the 8-cylinder or 4-cylinder scale.
4. Start and idle the engine at 800–1,000 rpm. Dwell should be 23° when read on an 8-cylinder scale, or 46° on a 4-cylinder scale.
5. If dwell is not correct, adjust the point gaps as outlined above so that the meter gives the correct reading.

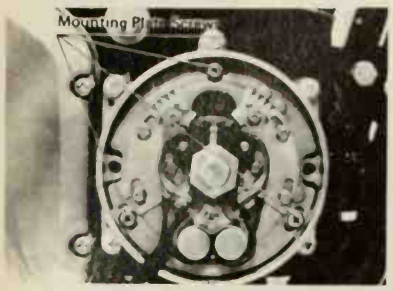
Ignition Timing

The breaker points on the left fire cylinders 1 and 4. Those on the right fire cylinders 2 and 3. Timing is set for each pair of cylinders.



Timing marks "1.4" and "2.3" on the advancer are for the left and the right side points respectively.

STATIC TIMING



1. Clean and adjust the points as described in the "Contact Breaker Points" Section.
2. Rotate the engine until the "F" mark on the timing advancer for the set of points to be adjusted is slightly to the left of the timing mark located just above the advancer.
3. Connect a timing light or ohmmeter to the appropriate set of points with one lead on either the leaf spring or the points wire mounting bolt, and the other on a ground

Aligning the timing mark

Adjusting the points adjusting plate

Mounting plate mounting screws

(i.e., an engine cooling fin, the frame, etc.). Turn on the ignition switch, if a timing light without a power source is used.

NOTE: *Leaving the key on will cause the points to burn and pit, so leave it on only when necessary.*

4. Rotate the engine until the "F" mark is aligned with the timing mark. The light should react as the two come together. If it does, the timing is correct and you should now do the other set of points; if not, go on to the next step.

5. Loosen the adjusting plate mounting screws, and use a screwdriver at the pry point to position the points so that they just begin to open as the timing marks come into alignment. Always rotate the engine back past the point of alignment by a few degrees before trying again. If the adjusting plate will not travel far enough to arrive at a suitable adjustment, loosen the 3 mounting plate screws and rotate the plate to provide more room for adjustment. Secure the screws and recheck the timing before going on to the other set of points.

DYNAMIC TIMING

1. Clean and adjust the points as described in the "Contact Breaker Points" Section.

2. Run the engine until its normal operating temperature is reached, and adjust the idle, if necessary, to within 800–1,000 rpm as described in the "Carburetor Synchronization and Adjustment" Section.

3. Connect the strobe light according to the manufacturer's instructions, so that the impulses from cylinders 1 and 4 are monitored. Aim the light at the timing marks. The "F" 1.4 mark should be aligned with the timing index mark. If it isn't, loosen the mounting screws, and use a screwdriver at the pry point until the marks do line up.

4. Repeat the above steps on the "F" 2.3 mark.

5. Advance the engine speed to about 2,900–3,100 rpm and check both sets of points. If the timing is off, the advance mechanism is probably at fault.

NOTE: *The idle speed can be regulated by either the throttle stop screw or the throttle grip tensioner.*

6. If the timing is unsteady, remove the contact breaker plate assembly and examine the advance unit. Look for weak or broken springs, or a bent advancer shaft. If either spring is defective, replace both of them. If the advancer shaft is bent (noticeable as the engine is turned over), remove the advancer unit and bend the shaft until total run-out is less than 0.004 in. (0.1 mm), or replace the assembly. When reinstalling the advance unit, make sure that the pin is located in the hole.

ELECTRONIC IGNITION

The ignition timing is pre-set. Due to the nature of the system, no routine maintenance is required.

CARBURETOR SYNCHRONIZATION AND ADJUSTMENT

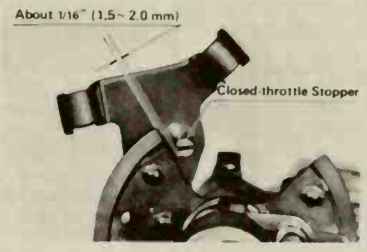
Preliminary Adjustment

1973 MODELS

Perform the following operations as a prelude to the actual adjustment anytime the carbs are rebuilt or replaced, of if the engine idles especially rough.

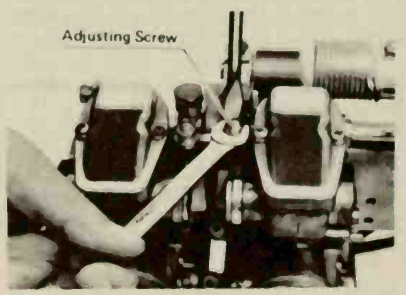
1. Remove the carburetors.

2. Turn the throttle stop screw in or out until there is about ⅜ in. (10 mm) between the bracket and the underside of the screw head.

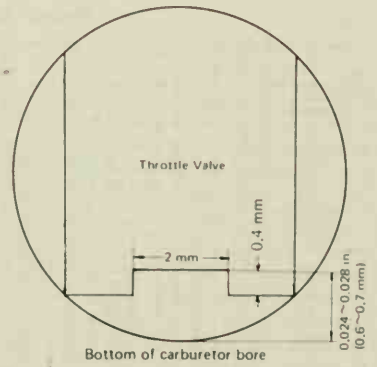


3. Loosen the closed-throttle stopper locknut, and rotate the eccentric stopper screw until there is about 1/16 in. (1.5–2.0 mm) clearance between the stopper and the top of the pulley.

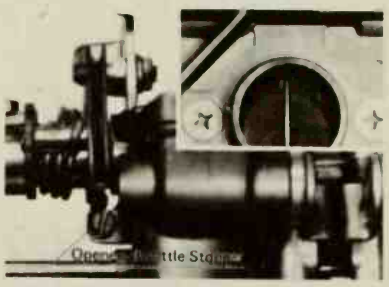
4. Locate the notch cut into the throttle valve, then loosen the locknut and rotate the adjusting screw until there is about 0.024–0.028 in. (0.6–0.7 mm) clearance between the notch and the bottom of the carburetor bore, and secure the locknut.



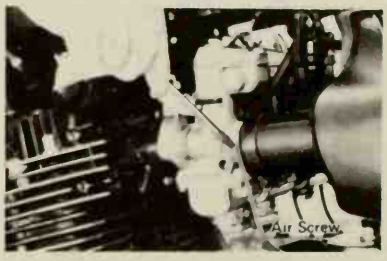
NOTE: *This is a very delicate operation which must be performed on each of the carbs, so that the adjustment is as close as possible for all 4.*



Throttle stop screw adjustment



Closed-throttle stopper adjuster



Throttle valve adjusting screw and locknut

Throttle valve clearance

Adjusting the opened-throttle stopper

Adjusting the pilot mixture

5. Open the throttle by rotating the pulley until the bottom edge of the lowest of the 4 throttle valves is even with the top of the carburetor bore, then rotate the open-throttle stopper screw so that the pulley is stopped at that point.

6. Gently turn each of the carburetor pilot screws into their seats, then back them all out 1½ turns.

1974–76

1. The procedure is to be carried out anytime the carburetors have been rebuilt or replaced, or if the engine runs very roughly.

2. The procedure for 1974 and later models is essentially the same as for 1973 models as outlined above except for the following points:

a. The clearance between the closed throttle stopper and the top of the pulley (Step 3) should be 2–3 mm (about ⅛ in.).

b. The pilot screws (Step 6) should be turned 1¼ turns off their seats.

Adjustment

1973–76

1. Turn the pilot screws in until they bottom lightly, then turn each of them out 1½ turns on 1973 models or 1¼ turns on 1974 and later machines. Run the engine for at least 5 minutes until normal operating temperature is reached, then adjust the engine idle speed

using the throttle stop screw until the idle speed is about 800–1,000 rpm according to the tachometer.

2. Adjust the pilot screw on each carburetor to that position where the highest idle speed is reached. If the idle speed exceeds the limits given in the previous step, lower the idle speed to within the limits using the throttle stop screw.

NOTE: *If any pilot screw can be turned to within ½ turn from its seat without any appreciable rise in idle speed, there is probably something wrong inside that carb.*

3. Turn in each pilot screw evenly some small arbitrary number of turns (i.e., ¼–½ turn), then readjust the idle speed to within the specified limits.

4. Adjust the manifold vacuum of each carburetor using one of the following methods, depending on the equipment available. The machine should be standing in a good airflow to keep the engine operating temperature down.

Without Vacuum Gauges

This procedure is very imprecise by its very nature and should not be attempted except in "emergency" situations. Vacuum gauges are virtually essential.

1. Pay careful attention to the exhaust noise, and place your hands behind the mufflers to feel the exhaust pressure.

2. Compensate for any variations in exhaust noise or pressure by making adjustments to the throttle valve adjusting screws for the carburetor(s) in question. Use either the special tool (Part No. 57001-120), or suitable substitutes to loosen the locknut and rotate the adjusting screws. Backing the screw(s) out will increase pressure, and turning it in will decrease it. Try to keep the idle speed as low as possible while maintaining a balanced pressure for all 4 carbs. Be sure to secure each locknut while holding the adjusting screw steady with a screwdriver.

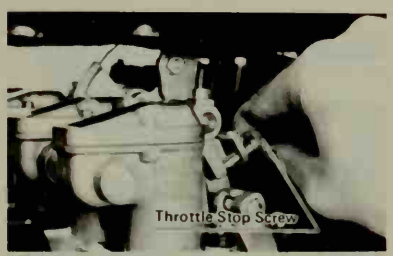
CAUTION: *If the special tool is not available, you can use a screwdriver and a box-end wrench, but be careful not to bend or place excessive pressure on any of the adjusting screws while loosening or securing the locknuts as this may cause damage to the carburetor.*

NOTE: *Adjusting the vacuum on one carb will cause changes in the pressure on all of the others, so be prepared to compensate for this.*

3. Readjust the pilot screws on any carburetors which have been readjusted, then readjust the idle speed to within 800–1,000 rpm by adjusting the throttle stop screw.

With Vacuum Gauges

1. Remove the rubber caps from the vacuum fittings on the cylinder head (Engine Nos. up to Z1E-01000) or carb holders (Engine No.s from Z1E-02174), and attach the vacuum gauges.



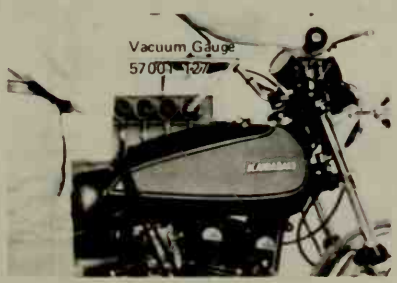
2. With the engine running at idle speed, close down the vacuum gauge intake valve until the gauge needle flutters less than 2 cm Hg (0.8 in. Hg).

3. The normal manifold vacuum gauge reading is 20–23 cm Hg (8–9 in. Hg) for each cylinder. If any gauge reads less than 15 cm Hg (6 in. Hg), recheck the pilot screw adjustment, and make sure that the carb holder hose clamps and spark plugs are secure.

4. Balance the carbs by readjusting the throttle valve adjusting screws as described in Step 2 of the "Without Vacuum Gauges" Section. All of the carbs should be adjusted to within 2 cm Hg (0.8 in. Hg) of each other. Read the Caution after Step 2.

5. Open the throttle and allow it to snap shut several times while watching to see if the vacuum gauge readings remain the same. Readjust any carburetor whose reading has changed.

6. Remove the vacuum gauges, replace the rubber covers, readjust the pilot air screws on any carbs which have been adjusted, and adjust the idle speed to about 800–1,000 rpm.

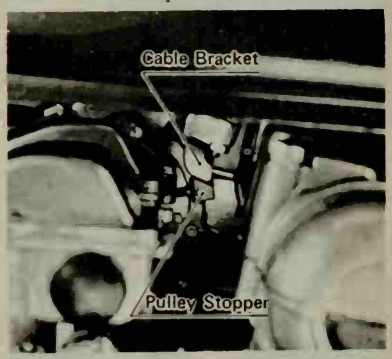


Adjusting the throttle stop screw

Vacuum gauge fitting (shown is a later model; earlier models were pressed into the head)

Adjusting the throttle valves using the special tool

Vacuum gauge installation



NOTE: *Inability to obtain synchronization or proper idling may be due to incorrect carburetor float levels, obstruction of air or fuel passages, etc. Refer to "Fuel Systems."*

Preliminary Adjustment
1977–80

1. The preliminary adjustment should be carried out anytime the carburetors have been rebuilt or replaced or if the engine runs very roughly.

2. Turn the idle adjusting screw to give 1.6–2.0 mm (about 1/16 in.) between the throttle cable bracket end and the stopper on the pulley.

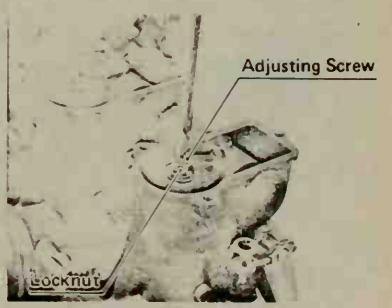
3. Push the throttle completely closed. Clearance between the bracket end and the stopper should be zero, and should return to 1.6–2.0 mm when the throttle is released. If it will not do this, replace the cable bracket.

4. Remove the carburetors from the motorcycle.

5. Remove the carburetor caps.

6. On each carburetor, loosen the adjusting screw locknut and turn the screw so that there is 0.7 mm (0.028 in.) between the throttle valve and the bottom of the carburetor bore. Tighten the locknuts and install the carburetor caps.

7. Open the throttle pulley until the bottom edges of the carburetor valves are even with the top of the carburetor bores. Adjust the pulley stop screw so that the pulley travel will be stopped at that point.



8. Remove the carburetor float bowls.

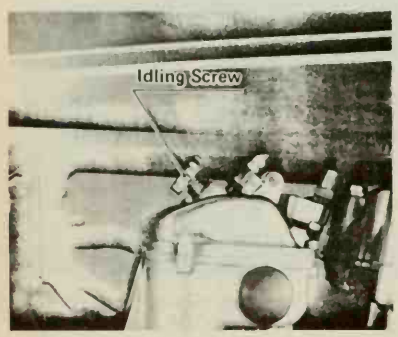
9. Turn each pilot screw in until it bottoms lightly, then back each one out 1¼ turns. Install the float bowls.

10. Refit the carburetors and adjust the cables.

Adjustment
1977–80

1. Start the engine and allow it to reach operating temperature.

Adjusting the throttle valves

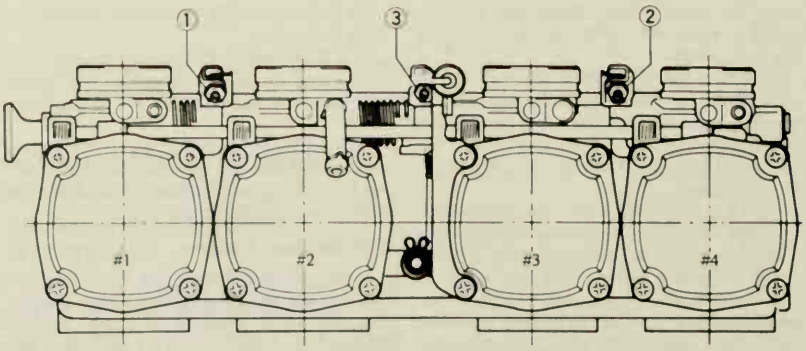


2. Use the idling screw to set the idle speed to 950–1050 rpm. Snap the throttle open a few times to ensure that the idle speed does not change.

3. Remove the gas tank and install an auxilliary tank to supply fuel to the carburetors during the synchronization procedure. Install the vacuum gauge set.

4. With the engine idling and at operating temperature, not the vacuum gauge readings. Normal vacuum should be 24–28 cm Hg (8–9 in. Hg), with the difference between cylinders being less than 2 cm Hg (0.8 in. Hg).

5. If the vacuum difference between cylinders is more than 2 cm Hg, remove the carburetor caps, loosen the adjusting screw locknuts, and turn the adjusting screw(s) so that idle vacuum for all four cylinders is as close as possible.



6. Tighten the adjusting screw locknuts. Readjust the idle speed, if necessary. Open and close the throttle a few times to ensure that the adjustments remain the same.

1981

These models are fitted with CV-type carburetors.

Adjustment procedure is basically the same as described for 1977–80 models, above. Note the following points:

CV carburetor synchronization screws (1,2,3)

a. disconnect the fuel tap and two vacuum switch hoses. Put the petcock on the "prime" position.

b. the adjustment screws are accessible without removing carburetor caps. There are three of them. Use the adjustment screw on the left to lower cylinder No. 1 vacuum. Use the screw on the right to lower cylinder No. 4 vacuum. The center screw will lower cylinders Nos. 1 and 2 simultaneously.

ENGINE AND TRANSMISSION

NOTE: *For engine rebuilding techniques and component inspection methods, refer to the "Engine Rebuilding" section under "General Information."*

ENGINE REMOVAL AND INSTALLATION

Removal

1. Remove the engine and oil filter drain plugs, and allow the engine to drain thoroughly.

NOTE: *If the engine will not run and therefore cannot be warmed as an aid in draining the oil, kick it through several times to assure as complete a drainage as possible.*

2. Remove the plastic side covers, open and unhook the seat, turn the fuel tap to the "S" poition, disconnect the fuel lines, disengage the gas tank tang from the rubber retaining band, and pull the tank off from the back.

3. Disconnect the black and green ignition coil leads at the coils, then disconnect the spark plug leads at the plugs.

Disconnecting the coil leads

Removing the carburetor assembly

Removing the air cleaner assembly

Removing the keepers

4. Unscrew the tachometer cable at the cylinder head, and place it out of the way.

5. Disconnect the blue connector at the electrical panel, then disconnect the starter wire at the starter relay terminal.

6. Remove the right footrest, then unbolt the battery ground wire (–) from the engine.

7. Loosen the 8 clamps which secure the carburetor assembly, then pull the assembly off to the rear. The throttle cables can now be discounnected at the pulley with greater ease.

8. Remove the screen from the top of the air cleaner, slide back the clamp on the oil breather hose, disconnect the hose, and remove the air cleaner assembly.

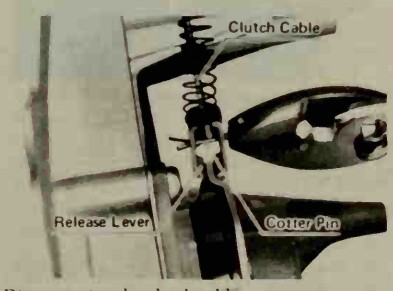
9. Remove the nuts which secure the exhaust pipe collars, free the collars from the cylinder head studs, and remove the split keepers.

10. Remove the exhaust system rear mounting bolts, then push the two mufflers on either side forward to remove them. If you wish to contend with each pipe individually, disconnect the muffler connecting hose clamp from each pair.

11. Remove the left front footrest, shift lever, and starter cover and gasket.

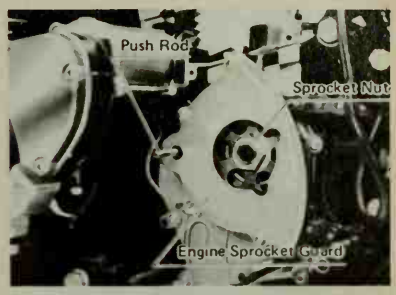
12. Remove the chain oiler pump cover, if fitted, disconnect the inlet hose from the pump, and plug it with a screw as shown in the illustration.

13. Remove the chain cover, pull the cotter pin out of the clutch release lever, disengage the clutch cable, remove the engine sprocket guard, and remove the clutch pushrod from the driveshaft.

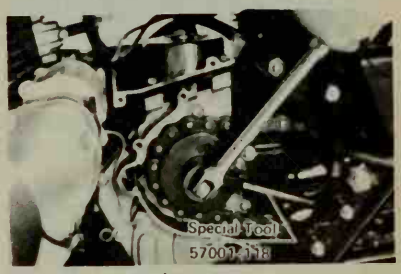


14. Bend back the lockwasher locking tab, secure the sprocket with either the special tool (Part No. 57001-118), or a suitable substitute, and remove the sprocket nut and sprocket.

15. On rear disc brake models, remove the rear brake master cylinder bolts and side cover bracket. Remove the brake lamp switch and spring, back off the brake rod adjusting nut until maximum pedal play is reached, then loosen the brake pedal position adjusting bolt locknut, and back out the bolt so that the pedal is held down, out of the way.

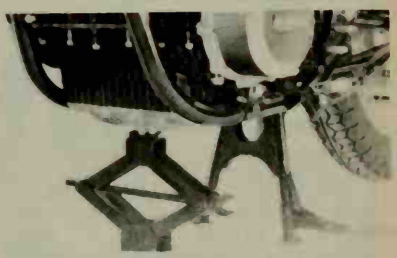


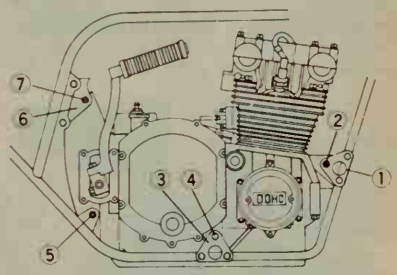
16. Jack or lever the engine up to take the weight off the mounting bolts, then remove the nuts from the 3 long engine mounting bolts.



Securing the intake hose

Disconnecting the clutch cable





Removing the sprocket nut

17. Remove the short engine mounting bolt from the lower center mounting on each side, the right rear engine mounting bracket

Keeping the pedal out of the way

Engine mounting bolt locations

1. Front bracket
2. Front bolt
3. Lower center bracket
4. Lower center bolt
5. Rear lower bolt
6. Rear upper bracket
7. Rear upper bolt

The brackets must be clear before the engine can come free

bolts, the center and right side front mounting brackets, and the 3 long bolts.

18. With the engine held level, slowly lift it up about 1 in., then move it to the right slightly until the rear of the engine slips over the lower right rear mounting.

19. Raise the front of the engine a little so that it will clear the frame, then drop down the left side, and pull the engine out diagonally and upwards to the right.

Installation

1. Mount, but do not secure, the 3 engine mounting brackets before inserting the engine bolts. Insert the engine bolts, secure the bracket mounting bolts, and then tighten the engine mounting bolts. The 3 long bolts are inserted from the left side of the machine. Two spacers go on the rear upper bolt; a long one on the left side of the engine, and a short one on the right side. Secure the bracket bolts to 14.5–16.5 ft lbs (2.0–2.3 kg/m), the 3 long (12 mm) bolts to 47–50 ft lbs (6.5–7.0 kg/m, and the two shorter bolts (10 mm) to 26–29 ft lbs (3.5–4.0 kg/m).

2. Install the engine sprocket with the chain already on it, and secure the sprocket nut to 87–108 ft lbs (12–15 kg/m). A new lockwasher should be used, and the chain adjustment can be loosened if the sprocket and chain will not go on the shaft. Note that the sprocket must be installed with the stamped numbers facing the engine. Otherwise chain alignment will be incorrect.

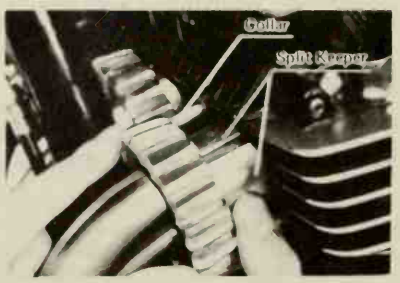
3. An oil seal guide (Part No. 57001-130), or a suitable substitute, should be used when installing the chain cover in order to avoid damaging the rubber seal. The pin in the output shaft must be aligned with the groove in the chain oil pump shaft before the cover will go on, on models with a rear chain oiler.

4. Install the carburetor assembly, taking care that the clamps are secured well enough to prevent any air leaks.

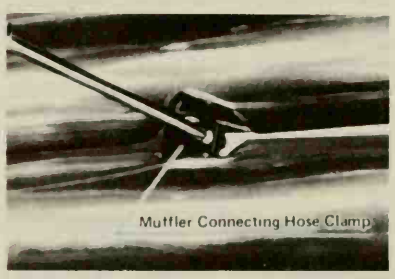
5. Install the inside mufflers first, and then the outside ones. The collar can be used to hold the split keeper while installing the pipe. Secure the muffler connecting hose clamp to prevent any exhaust leaks, then secure the rear mounting bolts and the bolts at the cylinder head, in that order.

6. Connect the spark plug wires to the plugs. The wires are numbered in accordance with their respective cylinders counting from left to right.

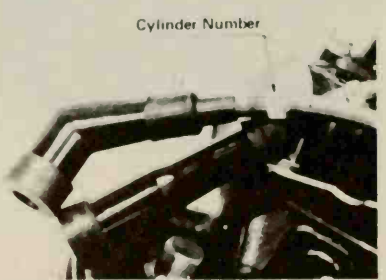
7. Replenish the oil supply with high quality (SE) oil, and kick the engine through several times to circulate the oil before firing it up. Refer to the "Maintenance" Chapter for capacities.



8. Give the machine a thorough going over, and make all the necessary adjustments.



Using the guide to protect the cover oil seal



Lining up the pin and groove

Installing the split keepers and collar

Securing the hose clamp

Put the right leads on the right plugs

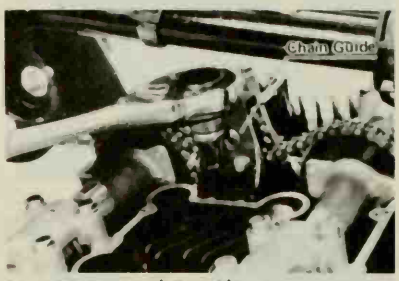
TOP END

Camshafts

REMOVAL

1. Remove the gas tank.

2. Remove the tool tray. Remove the air cleaner silencer.



3. Disconnect the spark plug leads. Remove the contact breaker cover and gasket.

4. Turn the engine over until the "T" mark for cylinders 1 and 4 lines up with the timing mark.

5. Remove the valve cover and gasket.

6. Remove the chain guide sprocket, then unbolt the camshafts caps and separate the split bushing halves for installation in their original positions unless they are to be replaced. Remove the camshafts.

7. Unscrew the tachometer cable, and remove the tach pinion to avoid any possible damage to the camshaft worm during the installation procedure.

Removing the cam chain guide

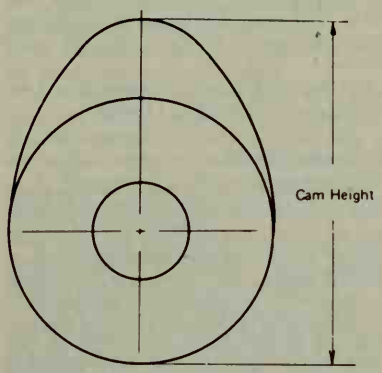
Removing the bushings and caps

Removing the exhaust camshaft

INSPECTION

1. Clean all parts in a suitable solvent, then blow them dry.

2. Inspect the camshafts for signs of wear, scored lobes, or damage, and replace them as necessary based on the following information.



a. Measure the height of each cam lobe with a micrometer, and replace the cam as necessary if the lobes are worn past their serviceable limits as given below:

900

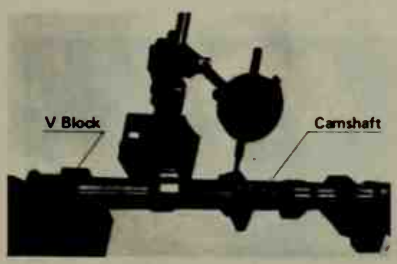
	Standard	*Service Limit*
Intake	1.4276 ~ 1.4307 in. (36.26 ~ 36.34 mm)	1.4236 in. (36.16 mm)
Exhaust	1.4079 ~ 1.4110 in. (35.76 ~ 35.84 mm)	1.4039 in. (35.66 mm)

1000

	Standard	Service Limit
Intake	1.4256 ~ 1.4327 in. (36.21 ~ 36.39 mm)	1.4220 in. (36.12 mm)
Exhaust	1.4059 ~ 1.4200 in. (35.71 ~ 35.89 mm)	1.4024 in. (35.62 mm)

Make the measurement along here

b. Measure the diameter of each of the camshaft bearing surfaces with a micrometer, and replace the camshaft as necessary if either bearing surface is worn past its serviceable limit:



Standard	Service Limit
0.9633 ~ 0.9638 in. (24.467 ~ 24.480 mm)	0.9614 in. (24.420 mm)

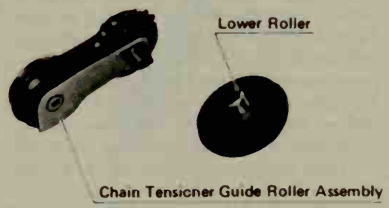
Measuring the bearing surfaces

3. Remove the cam chain sprocket from the camshafts, keeping them separate for replacement in their original locations, and place the shafts on V-blocks so that they ride on the bushing surfaces, or in a lathe. Rotate the shafts and use a dial indicator to check run-out along the sprocket mounting surface. Replace any cam whose run-out exceeds the service limit given below:

Standard	Service Limit
under 0.0008 in. (under 0.02 mm)	0.004 in. (0.10 mm)

Checking camshaft run-out

4. Inspect the camshaft bushings for signs of wear, scoring, or damage, and replace them as a set per camshaft if worn past their serviceable limit of 0.0063 in. (0.16 mm). The standard clearance between the bushings and the camshafts is 0.008–0.0025 in. (0.020–0.064 mm). Measure the clearance in the following manner:



Checking bearing wear with plastigage

a. Remove the camshafts and cut sections of Plastigage® to the width of the bushing, and place a strip on the lower half of each bushing, parallel to the camshaft, and so that the plastigage will be between the bushing and the shaft.

b. Fit the cam chain over the sprocket so that the cam is held stationary, and fit and secure the caps and bolts as directed in the "Camshaft Installation" Section.

c. Remove the camshaft and use a micrometer to measure the plastigage in order to determine the camshaft/bushing clearance. Excessive clearance in any of the 4 bushings for each of the camshafts will necessitate replacing all 4 bushings for that cam.

5. The cam chain is of the endless variety, and should not be removed unless replacement is necessary. In most cases excessive chain noise can be traced to wear of the guide rollers, in which case they should be replaced.

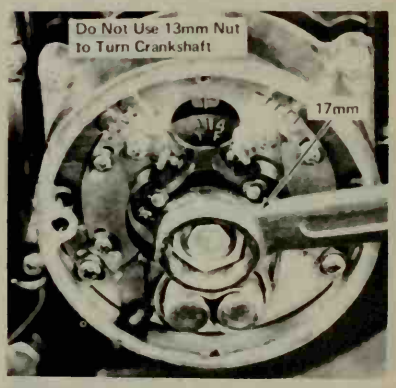
Check these for wear

Consult the "Crankshaft" Section for cam chain replacement information if this becomes necessary.

6. Inspect the cam sprockets for signs of wear or damaged teeth, and replace them as necessary. If one sprocket is damaged, the chances are good that the other is also in need of replacement, and the chain has probably also been affected. It's best, for that reason, to replace the sprockets and chain as a complete system.

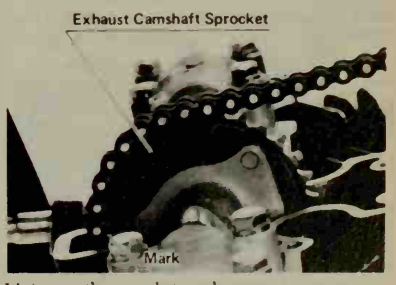
NOTE: *On models with engine numbers before Z1E-04654, there have been instances of severe engine damage caused by the sprocket mounting bolts loosening and backing out. A new shouldered bolt (Part No. 92003-41) is available, and should be used to replace the original bolts. Use Liquid Lock-Super (Part No. K41012-014) or a suitable thread locking compound, and torque the bolts to 7 ft lbs (1.0 kg/m).*

A sprocket secured with a new type bolt



INSTALLATION AND CAMSHAFT TIMING

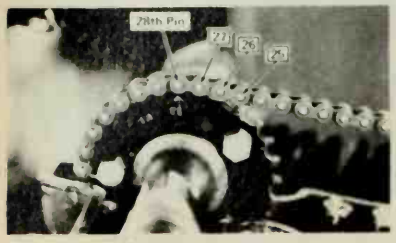
1. Installation is basically in the reverse order of removal. Use new gaskets whenever possible.



2. Remove the breaker point cover, then rotate the crankshaft, using a wrench on the large crankshaft nut while holding the cam chain up so that it doesn't get caught and so that the slack between the crankshaft and the exhaust cam sprocket is taken up, until the "T" alignment mark for cylinders 1 and 4 is aligned with the timing mark. This brings the number 1 and 4 pistons into the TDC (top dead center) position.

3. Slip the exhaust camshaft through the cam chain, and position it so that the mark on the sprocket is aligned with the cylinder head surface and facing toward the front of the engine, then pull the chain taut and fit it onto the exhaust camshaft sprocket. The camshafts have "L" and "R" marked on them for installation purposes.

CAUTION: *The chain must be properly seated on the crankshaft and chain guide or the timing will not be accurate.*



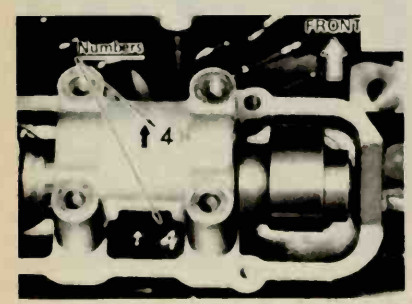
Rotate the engine forward

Lining up the sprocket mark

4. Starting with the next chain link pin above the one which coincides with the exhaust sprocket mark, count to the 28th, then slip the intake camshaft through the chain so the 28th pin and the "28" mark on the intake camshaft sprocket are aligned as illustrated.

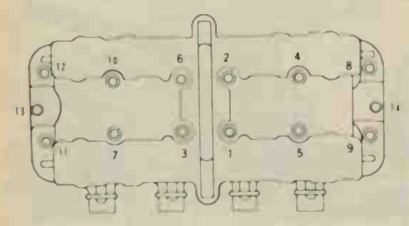
Lining up the 28th pin and mark

Start counting here



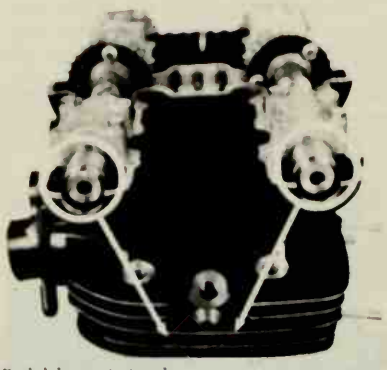
NOTE: *Do not begin counting at the exhaust sprocket mark; start at the next pin above that point.*

5. Position all the split bushing halves in their original locations unless they've been replaced.



6. Position the camshaft caps so that the arrow points toward the exhaust side, and so that the number on the cap matches the number on the head.

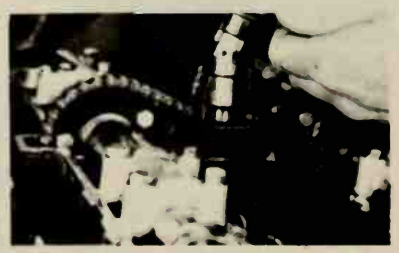
7. Seat the camshaft by partially tightening the left-side cap bolts, then fully torque all of the bolts to 105 in. lbs (1.2 kg/m) in the order shown in the accompanying illustration.



CAUTION: *If you are bench assembling the head without the cam chain installed, great care must be taken not to bend any valves by securing the bearing caps with the cams improperly positioned. Be sure that the cam lobes do not depress both valves of any one cylinder at the same time, and place styrofoam, under the head to prevent bending the valves on the bench surface. Do not tighten both camshafts into place at the same time, and do not secure the caps until the valve timing is set (Step nos. 2–4) with the cam chain in position.*

Match the stamped numbers when installing the bearing caps

Cylinder head bolt tightening pattern



Both lobes pointing down . . .

. . . will cause the valves to hit . . .

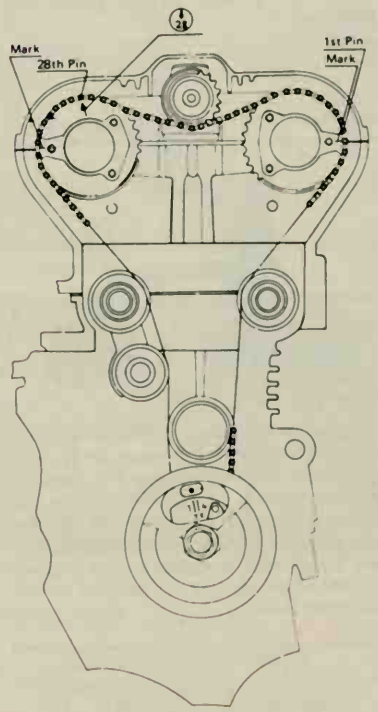
. . . and this is the result

8. Liberally oil the cam assembly, then install the chain guide sprocket assembly, and adjust the cam chain tension as described in the "Tune-Up" Chapter.

9. Rotate the crankshaft 2 or 3 complete revolutions until number 1 and 4 pistons are at TDC ("T" mark aligned with timing mark), then check that the marks on the exhaust and intake camshaft sprockets are properly aligned, as illustrated, indicating that the cam timing is correct.

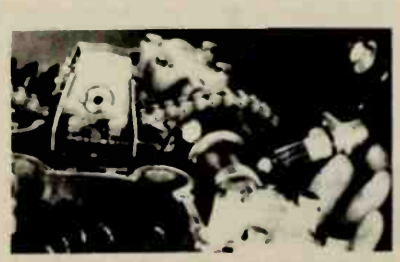
Securing the chain guide

CAUTION: *Do not attempt to rotate the engine by using a wrench on the camshaft sprocket mounting bolts; use the large nut on the crankshaft instead. If any unusual resistance is felt when rotating the engine, stop immediately and make sure that the timing is correct or valve damage may occur.*



10. Install the tachometer pinion and cable, then mount and secure the valve cover and cover gasket to 70 in. lbs (0.8 kg/m) torque.

11. Adjust the valve clearances as described in the "Tune-Up" Chapter.



Cylinder Head

The cylinder head is made of aluminum alloy into which the valve guides are pressed, and the valve seats are cast. The valve seats must be cut to their specified angles to assure efficient sealing, and to prevent the valve from overheating by promoting heat dissipation.

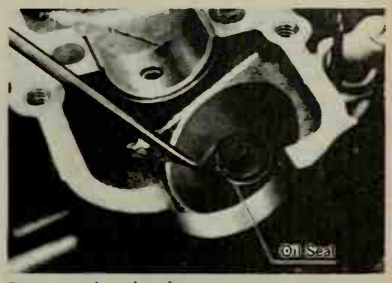
Normal wear to the valve lifter and cam surfaces can be adjusted for up to 0.04 in. (1.0 mm). Once this limit has been exceeded through seat wear or grinding, the valve stem end can be ground down to increase clearance. The head will have to be replaced if the adjustment limit is exceeded again.

Timing mark alignment

Installing the tachometer pinion

REMOVAL AND DISASSEMBLY

1. Fully open the seat, and remove the tank.
2. Remove the exhaust system as described in Steps 9 and 10 of the "Engine Removal" Section.
3. Remove the carburetor assembly after loosening the 8 hose clamps which secure it.
4. Remove the camshafts as described in the "Camshafts Removal" Section.
5. Disconnect the spark plug wires from the plugs, and remove the plugs.
6. Remove the bolt from either end of the heat, and the 12 cylinder head nuts using either the special tool (Part No. 57001-111) or any suitable socket wrench.
7. Remove all of the valve tappets and shims, keeping them separate for installation in their original locations.
8. Remove the cylinder head and head gasket. Tap the head with a soft mallet to break it free from its seat if necessary.
9. Compress the valve springs, using either the special tool (Part No. 57001-107) or a suitable substitute, until the split keepers can be removed, then remove the valve, springs, and spring retainer, keeping them separate for installation in their original locations.

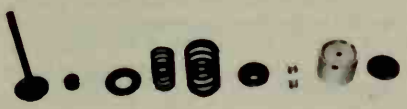


NOTE: *All of the valves do not necessarily have to be removed, however this is the recommended practice.*

10. Remove the oil seal from the valve guide, then heat the area around the guide with a torch to about 250°-300° F (120°-150° C), and drift the guide out from the bottom of the head using either the special drift (Part No. 57001-108) or a suitable substitute.

NOTE: *Do not remove any guide which doesn't have to be replaced. Any guide oil seal which is damaged or removed should be replaced. Consult Step 4 of the following section for additional information.*

Removing the head bolts



Removing the oil seal

6. Outer valve spring
7. Valve spring seat
8. Oil seal
9. Valve guide
10. Circlip
11. Exhaust valve
12. Inlet valve

INSPECTION

1. Clean all parts other than seals and gaskets in a suitable solvent, then blow them dry. Carbon deposits on the piston and head assemblies can be softened with a decarbonizing solvent, and scraped off with a blunt instrument such as a butterknife. Do not use a caustic soda solution to clean aluminum parts such as the head and pistons, however, it may be used on the valves. Avoid gouging the piston crown or removing any metal. It is not necessary to restore the components to a like-new condition. Periodically, as you work, wipe the surface clean with a clean rag soaked in clean gasoline. If this is done with the cylinder still in place, you can catch the carbon flakes by pressing a line of grease around the piston on top of the rings. Rotating the piston will leave the grease ring with the carbon trapped in it on the cylinder, and it can then be wiped out. The cylinder head assembly should be disassembled before being decarbonized.

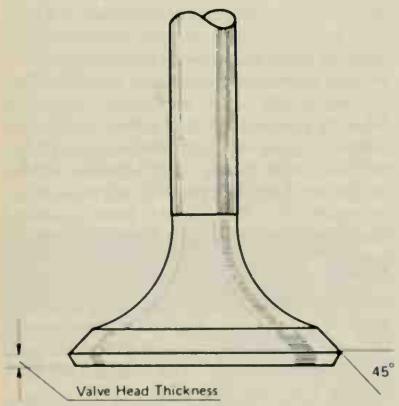
2. Inspect the cylinder head for warpage on the gasket surface by laying a straightedge across the head and measuring the distance between the straightedge and the gasket surface with feeler gauges. The standard warpage is under 0.002 in. (0.05 mm), and the serviceable limit is 0.10 in. (0.25 mm). If the warpage exceeds this limit, the head must be replaced. It is possible to straighten a warped head using one of the following procedures:

Checking the head for warpage

a. Place a sheet of fine grit emery paper on a flat surface and move the head around in a figure-eight motion while applying mild pressure. It is better to work slowly with mild pressure than quickly with heavy pressure. Don't remove any more metal than is necessary.

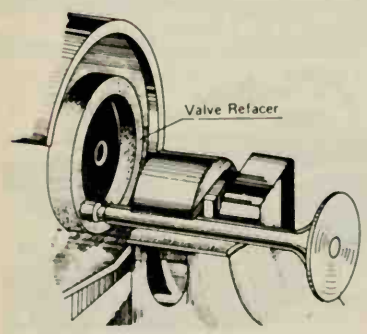
b. An alternative method is to use a piece of glass and a fine valve grinding compound instead of the emery paper.

c. Check the results with Prussian blue dye or red lead. To do this, lay out some very fine sandpaper on a flat surface. Coat the gasket surface on the head with the dye and allow it to dry. Move the head very gently over the sandpaper just long enough to remove the dye, then look at the gasket surface. If the head is flat, all of the dye will have been removed. If there is still dye on the heat, repeat the entire process, replace the head, or consult your local dealer.



3. Inspect the valves for a worn, bent, burned, or damaged condition, and replace them as necessary. Perform the following operations on each valve:

a. Measure the valve head thickness using vernier calipers, and replace the valve if the head is thinner than the service limit given below:



Standard	*Service Limit*
0.034 ~ 0.045 in. (0.85 ~ 1.15 mm)	0.020 in. (0.5 mm)

b. Carefully inspect the seating surface of the valve and the condition of the stem, and repair the valve if possible using a valve refacer. The valve seating surface angle is 45°.

c. Place the valve in a pair of V-blocks,

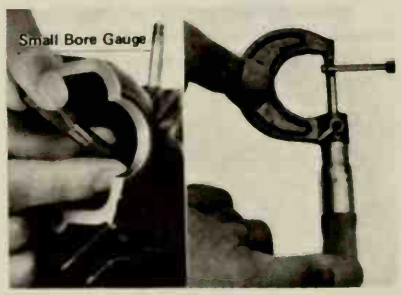
Measure valve head thickness here

Refacing the valve stem

and check its run-out with a dial indicator. The valve must be replaced if its run-out exceeds the service limit of 0.002 in. (0.05 mm).

d. Measure the valve stem in at least 4 places using a micrometer held at right angles to the stem, and replace the valve if it is worn past the service limits given below at any point:

	Standard	*Service Limit*
Intake	0.2742 ~ 0.2748 in. (6.965 ~ 6.980 mm)	0.272 in. (6.90 mm)
Exhaust	0.2738 ~ 0.2744 in. (6.955 ~ 6.970 mm)	0.272 in. (6.90 mm)



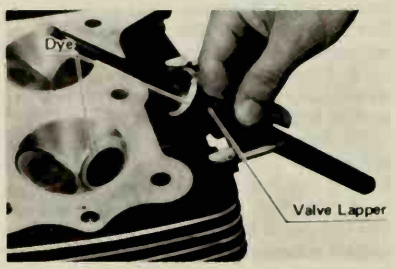
4. Measure the bore of each valve guide in at least 4 places, using a small bore gauge and a micrometer, and replace the guide if any of the measurements exceed the service limits given below:

Standard	*Service Limit*
0.2756 ~ 0.2762 in. (7.000 ~ 7.015 mm)	0.279 in. (7.08 mm)

If a bore gauge and micrometer are not available, insert a new valve into the guide, set a dial indicator against the stem, and move the stem back and forth to measure valve/valve guide clearance, then do it again while moving the stem in a direction at right angles to the first measurement. The guide will have to be replaced if the valve/valve guide clearance exceeds the service limits given below:

	Standard	*Service Limit*
Intake	0.002 ~ 0.005 in. (0.050 ~ 0.124 mm)	0.010 in. (0.25 mm)
Exhaust	0.003 ~ 0.006 in. (0.071 ~ 0.142 mm)	0.009 in. (0.24 mm)

5. Inspect the valve seat for signs of wear, scoring, burning, or damage, then measure the width of the seat. The seat must be smooth



Measuring valve guide inside diameter

Measuring valve/valve guide clearance

Valve seat dimensions

Checking valve/valve seat contact

and undamaged, and must measure 0.04–0.06 in. (1.0–1.5 mm). 30°, 45°, and two 60° cutters are available for valve seat repairs. Proceed in the following manner:

NOTE: *The following procedure will be of value only if the valve and seat are in good condition.*

a. Remove the valve and apply machinist's dye to the valve seat, then use a lapper to tap the valve lighty into place. The dye pattern on the valve will give an indication of the condition of the seat. Compare it with the illustration.

b. Carefully cut the seating surface with the 45° cutter, taking care to remove only as much metal as is necessary to provide a good surface.

c. Carefully cut the area inside the seting surface with the 30° cutter, and cut the area outside the seating surface with the 60° cutter. If done properly, the seating surface should be within the specified limits all the way around.

6. If the seat has just been cut, or if the seat looks alright and you just wish to ensure a good seal between the seat and valve, lap the valves in at this time in the following manner:

a. Lightly oil the valve stem and insert it into the guide.

b. Apply a light coat of lapping compound to the seat. It is best to apply a few evenly spaced daubs rather than a random application, and it's a good idea to start off with coarse compound and finish with fine compound.

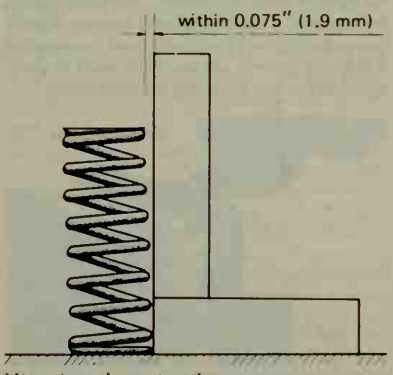
c. Slip a gas line, or a valve lapper, over

Cutting a valve seat

Lapping in a valve

the stem and rotate it back and forth in your hands while applying mild pressure against the seat by pulling on the gas line. Stop and clean the seat periodically to check on your progress.

d. Clean the seat area when smooth, and assemble the valve. Pour some gas into the spring side of the head and allow the head to sit. If there is no leakage through the seat after 15 minutes, the lapping has been successful.



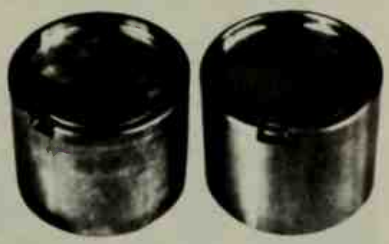
7. Inspect the valve springs for a pitted, collapsed, or damaged condition, and replace them as necessary. Perform the following checks also:

a. Measure the valve spring free lengths using vernier calipers, and replace the springs as a complete set if any are shorter than the serviceable limits given below:

	Standard	Service Limit
Inner	1.42 in. (36.0 mm)	1.38 in. (35.0 mm)
Outer	1.55 in. (39.3 mm)	1.50 in. (38.0 mm)

Checking valve spring free length

b. Stand each spring up on a flat surface, and set a perpendicular reference point next to it. If any spring is tilted more than 0.075 in. (1.9 mm) on 900 models or 0.059 in. (1.5 mm) on 1000 models, replace it.



Measuring valve spring tilt

NOTE: *Valve springs should always be replaced as a complete set to assure efficient operation.*

8. Inspect the valve tappets and adjusting shims for signs of wear or damage and replace them as necessary.

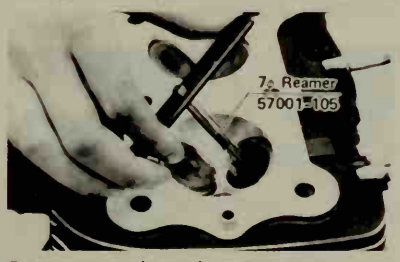
NOTE: *The type of valve tappets used in all models up to engine number Z1E-08979 have caused shim fracturing problems on some machines. A new redesigned tappet (Part No. 12032-005) is available as a replacement for the old type (Part No. 12032-004). It is recommended that all old style tappets be replaced. The new type of tappet, recognizable by the lack of a navel in the tappet/shim mating area, can be used in conjunction with the shim already in use, however this is not recommended as the old shim may have begun to fracture.*

The old style tappets should be replaced

ASSEMBLY AND INSTALLATION

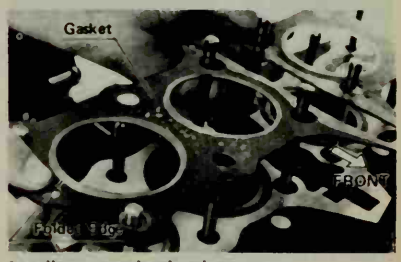
1. Assembly is basically in the reverse order of disassembly, and installation is in the reverse order of removal. Use new gaskets, valve guide seals, O-rings, and valve split keepers.

2. Install the circlip in its groove in the valve guide, and liberally oil the guide. Heat the area around the guide hole with a torch to about 250°–300° F (120°–150° C), and drive the guide in from the top of the head using either the special tool (Part No. 57001-108) or a suitable drift, until the circlip reaches its seat.



3. Use a 7 mm reamer to ream the guides. This must be done even if the old guides are used. Always rotate the reamer to the right, and keep rotating it as it's withdrawn.

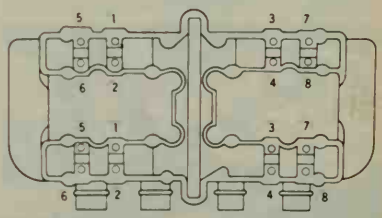
4. Lap the valve into its seat as directed in the preceeding "Inspection and Repair" Section.



5. Install the tappets and shims to their original locations.

6. Use a new head gasket to prevent compression leakage, and install the gasket so the side with the wider folded-over metal edges is facing up.

Drifting in a valve guide



Reaming out a valve guide

Installing a new head gasket

7. Tighten the cylinder head nuts gradually and evenly to 25 ft lbs (3.5 kg/m) on 900 models or 27–31 ft lbs (3.7–4.3 kg/m) on the 1000 in the order shown in the accompanying illustration.

Bolt tightening pattern

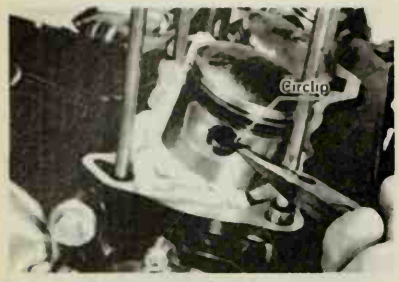
8. Secure the two end bolts to 105 in. lbs (1.2 kg/m).

9. Adjust the valve clearances before installing the valve cover, and use a new cover gasket.

Cylinder and Piston

REMOVAL AND DISASSEMBLY

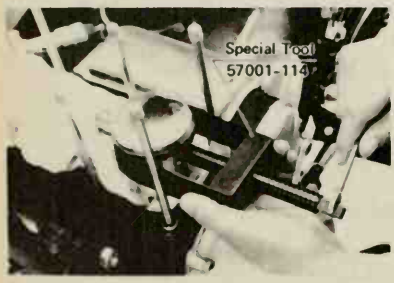
1. Remove the cylinder head as described in the previous Section, then remove the cam chain tensioner assembly and guide sprocket.



Removing the tensioner and guide sprocket assemblies

2. Loosen the cylinder block by gently tapping up on alternate ends with a soft mallet, then lift the cylinder and gasket off the crankcase studs. A pry point at the crankcase joint is provided on some models.

CAUTION: *As you lift the cylinder block, stuff clean rags in the crankcase openings to prevent foreign matter, such as broken*



rings, from falling into the crankcase, and to prevent possible piston damage caused by pistons striking the crankcase studs.

3. Remove the piston pin circlips with a pair of needle-nosed pliers, then remove the piston pin with the special tool (Part No. 57001-114 for the 900, 57001-910/914 for the

Removing the piston pin circlip

1000) or a suitable substitute. The pins can be removed also by heating the piston crown with a torch, and driving the pin out while carefully supporting the connecting rod to prevent damage to it or the big end bearings. Keep the pins with their pistons, and mark the pistons for replcement in their original positions.

Removing the piston pin

4. Remove the piston rings using either the special tool (Part No. 57001-115), a suitable substitute, or by hand, taking care not to damage the piston. When removing rings by hand, spread the ring ends with your thumbs, and

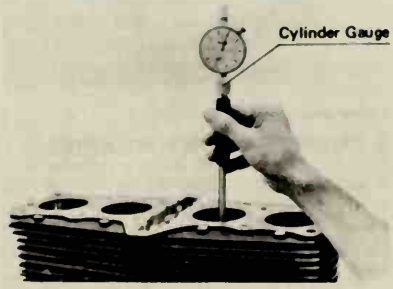
Removing the rings with the special tool

push up on the opposite side of the ring to remove it.

NOTE: *Do not remove the rings unless you are planning to replace them, as rings shouldn't be reused once they've been removed.*

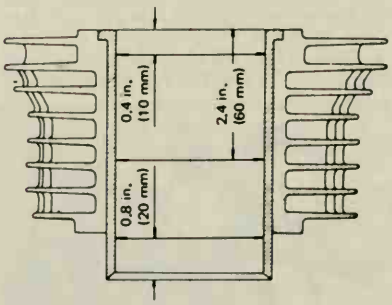
INSPECTION

1. Clean all parts other than gaskets, O-rings, and seals, in a suitable solvent, then blow them dry taking care to blow clear all oil passages. Decarbonize all components as described in the preceding "Inspection" Section. Piston ring grooves can be cleaned with a broken piece of piston ring.



2. Inspect the cylinder block for damage to the cooling fins or either of the gasket mating surfaces, or for badly scored cylinder walls, and replace the assembly as necessary. Use a cylinder gauge to check the cylinder wall dimensions of each cylinder in the three areas shown, and take two measurements at 90° from one another, at each location. If any of the measurements exceeds the service limits given below, or if there is a difference of more than 0.002 in. (0.05 mm) between any two measurements, all the cylinders will have to be bored and honed.

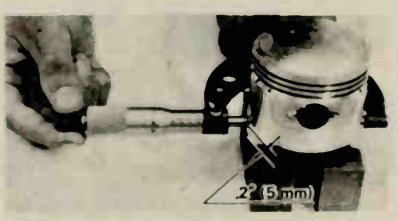
900



Standard	Service Limit
2.5984 ~ 2.5992 in. (66.000 ~ 66.019 mm)	2.602 in. (66.10 mm)

1000

Standard	Service Limit
2.7559 ~ 2.7567 in. (70.000 ~ 70.019 mm)	2.7598 in. (70.10 mm)



Measuring the cylinder bore

Cylinder bore measurement points

3. Measure the piston diameter at a point about 0.2 in. (5 mm) up from the bottom of the piston skirt and at right angles from the piston pin holes. Replace the piston if the diameter is under the service limits:

Measuring the piston

900

Standard	Service Limit
2.5956 ~ 2.5965 in. (65.93 ~ 65.95 mm)	2.590 in. (65.80 mm)

1000

Standard	Service Limit
2.7535 ~ 2.7543 in. (69.94 ~ 69.96 mm)	2.7480 in. (69.8 mm)

4. Subtract the piston diameter from the cylinder measurement to arrive at the piston/cylinder clearance. The clearance must be returned to standard whenever the cylinder is replaced or bored, however, if only the piston is replaced, clearance may exceed the limit, but must not be less than the minimum clearance of 0.0025–0.003 in. (0.060–0.079 mm) (900) or 0.0020–0.0028 in. (0.050–0.069 mm) (1000).

5. When boring and honing the cylinders, adhere to the following rules:

a. The inside diameter of any cylinder must not vary by more than 0.0004 in. (0.01 mm) at any point along its bore.

b. Replacement pistons are available in 0.020 in. (0.5 mm) and 0.040 in. (1.0 mm) oversizes. If boring in excess of 1 mm over standard is every necessary, the cylinder block must be replaced since replacement sleeves are not made available by the factory.

c. To avoid cylinder distortion due to unbalanced metal temperatures, bore the cylinders in either the 2-4-1-3 or 3-1-4-2 order.

d. Allow the metal to cool completely after boring before taking any measurements, as the diameter may change due to the temperature incease.

e. After the boring is completed, the piston/cylinder clearance should be returned to standard.

6. In the event of piston seizure in the bore, the cylinder should be honed, or at least smoothed out with #400 emery cloth, and the piston should be treated likewise. Make sure that the rings are till free if they aren't to be replaced. If the damage is heavy, the cylinder will have to be bored and the piston replaced. Try and determine why the piston seized before running the engine again. Look for air leaks, improper mixture adjustments, improper timing, or insufficient piston/cylnder clearance.

7. Inspect the piston rings and ring grooves for signs of wear or damage. The rings should be replaced if their condition is even slightly questionable, and the piston must be replaced if the ring grooves are unevenly worn or damaged. Make the following measurements:

Measuring the piston ring grooves

a. Measure the width of the ring grooves using a thickness gauge, and replace the piston if the grooves exceed the service limits given below:

900

	Standard	Service Limit
Top Groove	0.059 ~ 0.060 in. (1.50 ~ 1.52 mm)	0.063 in. (1.60 mm)
Second groove	0.059 ~ 0.060 in. (1.50 ~ 1.52 mm)	0.063 in. (1.60 mm)
Bottom groove	0.098 ~ 0.099 in. (2.50 ~ 2.52 mm)	0.102 in. (2.60 mm)

1000

	Standard	Service Limit
Top groove	0.048 ~ 0.049 in. (1.23 ~ 1.25 mm)	0.052 in. (1.33 mm)
Second groove	0.048 ~ 0.049 in. (1.22 ~ 1.24 mm)	0.052 in. (1.32 mm)
Bottom groove	0.099 ~ 0.100 in. (2.51 ~ 2.53 mm)	0.102 in. (2.60 mm)

b. Measure the thickness of the piston rings using a micrometer, and replace the rings if worn thinner than the service limits given below:

900

	Standard	Service Limit
Top ring	0.0567 ~ 0.0573 in. (1.440 ~ 1.455 mm)	0.0535 in. (1.36 mm)
Second ring	0.0579 ~ 0.0587 in. (1.470 ~ 1.490 mm)	0.055 in. (1.40 mm)
Oil ring	0.0973 ~ 0.0980 in. (2.470 ~ 2.490 mm)	0.0945 in. (2.40 mm)

1000

	Standard	Service Limit
Top and Second rings	0.0461 ~ 0.0469 in. (1.170 ~ 1.190 mm)	0.0433 in. (1.10 mm)

c. Measure the clearance between the ring grooves and rings using a thickness gauge at various pints around the piston, and replace the necessary components if the clearance exceeds the service limits given below:

900

	Standard	Service Limit
Top ring	0.0018 ~ 0.0031 in. (0.045 ~ 0.080 mm)	0.007 in. (0.18 mm)
Second ring	0.0004 ~ 0.0020 in.	0.006 in.
Oil ring	(0.010 ~ 0.050 mm)	(0.15 mm)

1000

	Standard	Service Limit
Top ring	0.0016 ~ 0.0032 in. (0.040 ~ 0.080 mm)	0.0059 in. (0.15 mm)
Second ring	0.0012 ~ 0.0028 in. (0.030 ~ 0.070 mm)	0.0059 in. (0.15 mm)

d. Measure ring end gap by placing the ring in a new cylinder, and using a thickness gauge to determine wear. If a new cylinder is not available, make the measurement at the bottom of the least worn cylinder where wear is minimal. If the gap is less than the limits given below, the ring ends can be filed as long as care is taken to file them flat, and if all burrs are removed. If the gap is worn greater than the service limits, the ring must be replaced.

900

Standard	Service Limit
0.008 ~ 0.016 in. (0.2 ~ 0.4 mm)	0.028 in. (0.7 mm)

1000

Standard	Service Limit
0.012 ~ 0.020 in. (0.30 ~ 0.50 mm)	0.032 in. (0.8 mm)

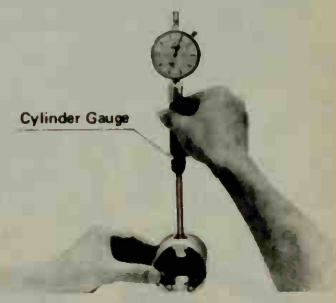
Measuring the piston ring end gap

NOTE: *Reusing used rings is not a recommended practice, however it can be done if the rings conform to all the specifications. For the best results, always replace rings in complete sets and hone all cylinders.*

e. Determine ring tension by measuring the ring gap while the ring is free. If the gap is less than the service limits given below, the ring is weak and should be replaced.

900

	Standard	Service Limit
Top ring	0.354 in. (9 mm)	0.236 in. (6 mm)
Second ring	0.354 in. (9 mm)	0.236 in. (6 mm)
Oil ring	0.315 in. (8 mm)	0.197 in. (5 mm)



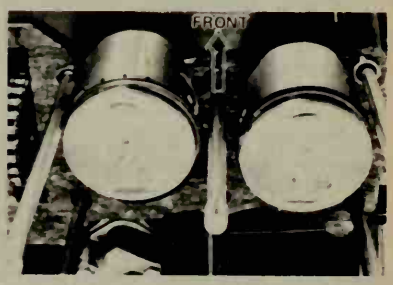
1000

	Standard	Service Limit
Top ring	0.28 in. (7.0 mm)	0.16 in. (4.0 mm)
Second ring	0.32 in. (8.0 mm)	0.20 in. (5.0 mm)

Determining ring tension

8. Measure the diameter of the piston pin using a micrometer, then measure the inside diameter of the piston pin hole in the piston, and the diameter of the connecting rod small end bearing. Replace the necessary components if the pin diameter is too small, or if the pin hole or bearing diameter is too large as indicated by the service limits given below:

	Standard	Service Limit
Piston pin	0.6691 ~ 0.6693 in. (16.994 ~ 17.000 mm)	0.6677 in. (16.96 mm)
Piston pin hole	0.6694 ~ 0.6701 in. (17.0035 ~ 17.0115 mm)	0.6724 in. (17.08 mm)
Small end O.D.	0.6694 ~ 0.6698 in. (17.003 ~ 17.014 mm)	0.6713 in. (17.05 mm)



Measuring the piston pin hole

NOTE: *When a new piston or pin is used, check that the piston-to-pin clearance is within the limits of 0.0026–0.00057 in. (0.0066–0.0145 mm), and that the pin-to-small end bearing clearance is within the limits of 0.00012–0.00079 in. (0.003–0.020 mm), and replace any necessary parts.*

ASSEMBLY AND INSTALLATION

1. Assembly is basically in the reverse order of disassembly, and installation is in the reverse order of removal. Use new gaskets, seals, O-rings, and piston pin circlips.

2. Liberally lubricate the piston pins before installing them, and install the pistons so that the arrow marked on the piston crown points forward.

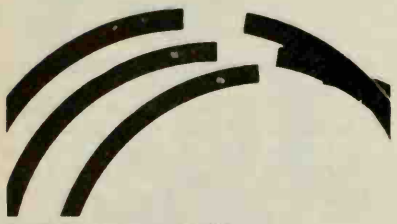
Be sure that the pistons are installed correctly

On 1000 models, if parts such as pistons or piston pins are being replaced, note the following:

a. Some piston pins are marked on the edge, and these should be used with pistons marked "A." Unmarked pins should be used with "B" pistons.

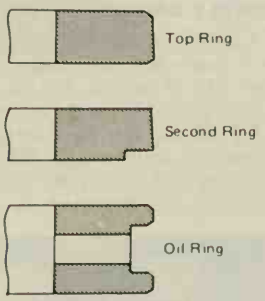
b. Install pistons marked "2" in cylinder bores with the same number, and unnumbered pistons in unnumbered bores.

CAUTION: *Do not attempt to drive in a pin without firmly supporting the connecting*



rod to prevent possible damage to the rod and big end bearing. Heat the piston crown with a torch or heated rags as an aid in installation.

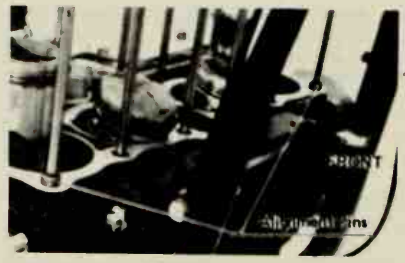
3. Always use new piston pin circlips, taking care to position the clip so that its open end is not aligned with either groove in the piston.



4. Install the piston rings with their lettered "N") side up. Be careful not to mix the first and second rings. The outer edge of the top ring is chamfered, and the lower outer edge of the second ring is notched as illustrated.

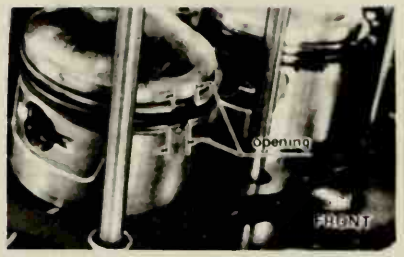
This will prevent the clip from coming free

Install the rings with the "N" up



The rings must go on the correct lands

NOTE: *The green coating on the top and bottom rings is to prevent scuffing, and is not intended to be permanent.*



5. Place the two alignment pins into the forward tension stud hole on either side of the crankcase. **Do not put the pins into the rear holes.** Apply a small amount of liquid gasket to the four innermost rear studs. Install the cylinder base gasket.

6. Rotate the top and bottom rings so that their end gaps are facing forward, and the center ring so that its gap faces the rear. On models with three-piece oil rings, stagger the rails about 30° on either side of the expander gap. Thoroughly lubricate the pistons and rings with fresh engine oil.

7. Lift up the cam chain so that it doesn't get caught, then rotate the crankshaft until all of the pistons are at about the same hight, and install the positioning rods (Part No. 57001-112 for the 900, 57001-532 for the 1000) to

Alignment pin installation

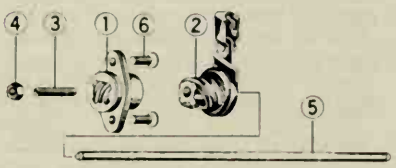
Aligning the ring gaps for maximum compression

Lining up the pistons with the special tool

hold them level. Wooden slats can be used effectively in place of the special tool.

8. Compress the piston rings using either the special positioning rod or ring compressors lubricate the cylinder walls thoroughly with fresh engine oil, and start the cylinder block down on the pistons. The ring compressors will have to be lowered and then removed as the rings enter the cylinder. Remove the positioning rod after the rings are in the bore.

NOTE: *It's a good idea to enlist the aid of a second set of hands during this operation so that one person can work with the cylinder block, and the other can keep track of the ring situation.*

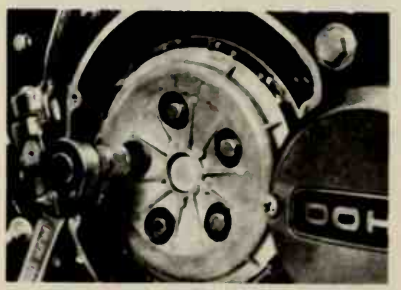


9. After the engine is fully assembled, tuned, and lubricated, crank it through several times before actually starting it to ensure adequate lubrication of the top end components.

CRANKCASE COVER COMPONENTS

Clutch

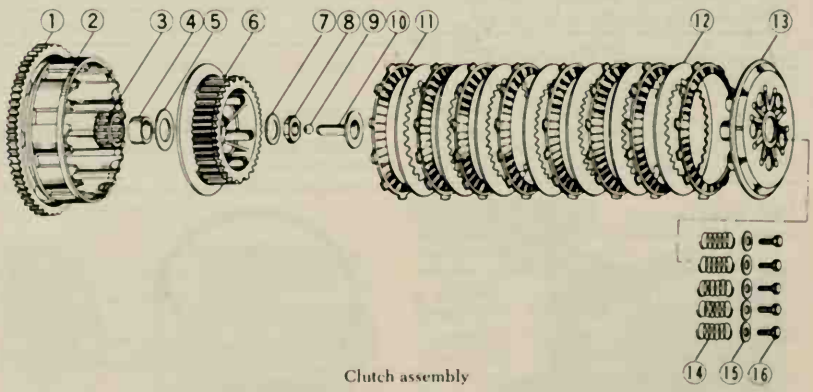
DISASSEMBLY



1. Drain the engine oil as described in the "Maintenance" section. The oil in the oil filter, and the filter assembly, can be left as is.

Clutch release mechanism assembly

1. Outer release gear
2. Inner release gear
3. Adjusting screw
4. Locknut
5. Pushrod
6. Screw

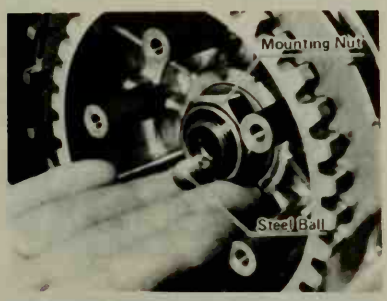


2. Remove the clutch cover and cover gasket, then remove the pressure plate bolts, clutch springs, and the pressure plate.

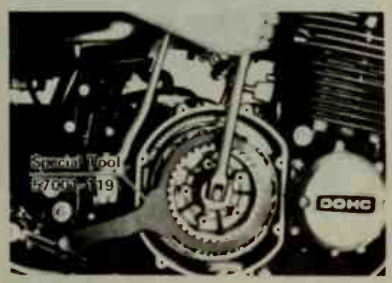
Removing the pressure plate bolts

3. Remove the clutch pushrod, and tilt the motorcycle so the steel ball (release bearing) will fall out.

NOTE: *The clutch assembly need not be further disassembled unless the clutch hub or housing is damaged.*



Clutch assembly



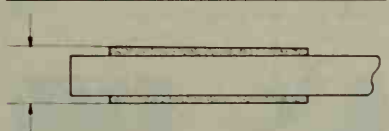
1. Reduction drive gear
2. Clutch housing
3. Needle bearing
4. Bushing
5. Washer
6. Clutch hub
7. Washer
8. Nut
9. Steel ball
10. Pusher
11. Friction plate
12. Steel plate
13. Pressure plate
14. Clutch spring
15. Washer
16. Bolt

4. Remove the clutch plates by either tilting the bike or by lifting them out with a hooked piece of wire, then keep the clutch hub from turning by using either the special tool (Part No. 57001-119) or a suitable substitute, and remove the hub mounting nut.

5. Remove the outer washer, the hub, and the inner washer. Clutch housing removal will necessitate complete engine disassembly with the engine removed from the frame as described in the "Splitting the Crankcases" Section.

Removing the release bearing

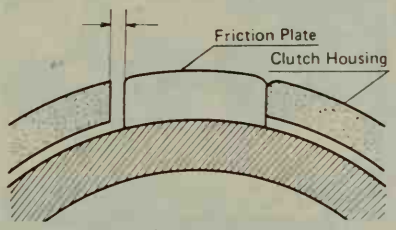
Removing the hub mounting nut



6. Remove the chain cover as described in the "Final Drive" Section of the "Chassis" section, then remove the clutch release inner gear by twisting it out, and the outer gear.

INSPECTION

1. Clean all parts other than the cover gasket and the friction plates in a suitable solvent, then blow them dry.



2. Inspect the clutch plates and discs for a worn, damaged, scored, or burned condition, and replace them as necessary. Friction discs should be replaced as a complete set if any are damaged or worn past the serviceable limits given below:

Standard	Service Limit
0.146 ~ 0.154 in. (3.7 ~ 3.9 mm)	0.134 in. (3.4 mm)

Measure friction plates here

3. Measure the clearance between the friction disc tangs and the fingers of the clutch housing using a thickness gauge. Excessive clearance will result in noisy operation. If you replace the discs check the clearance again, and if it still exceeds the service limit given below, replace the housing.

Standard	Service Limit
0.002 ~ 0.012 in. (0.04 ~ 0.30 mm)	0.020 in. (0.5 mm)

Measure clearance here

4. Place the clutch plates on a flat surface, and use a thickness gauge to measure warpage. Replace any plate if it is warped more than the limits given below:

	Standard	Service Limit
Friction plate	under 0.006 in. (under 0.15 mm)	0.012 in. (0.30 mm)
Steel plate	under 0.008 in. (under 0.20 mm)	0.016 in. (0.40 mm)

5. Inspect the clutch springs for a worn, pitted, or collapsed condition, and replace the entire set if any are worn past the following free length limits:

Standard	Service Limit
1.33 in. (33.8 mm)	1.27 in. (32.3 mm)

6. Inspect the clutch hub and housing for signs of wear or damage, and replace them as necessary. Light damage to any gear teeth can be repaired with an oilstone, but severely damage teeth, fingers, or hub splines will necessitate replacing the housing and/or hub.

7. Inspect the clutch pushrod, release bearing, and worm teeth of the release gears for signs of wear, pitting, or damage, and replace them as necessary. The release gears must be replaced as a set.

8. Inspect the pressure plate for signs of wear, fatigue, cracks, or severe warpage, and replace it as necessary.

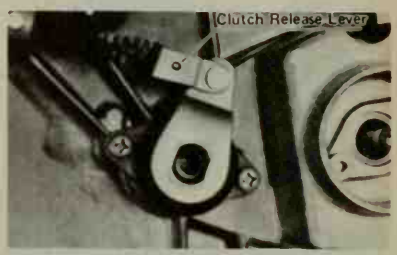
9. Inspect the clutch housing needle bearing for signs of discoloration, wear, or other visible damage and replace it if necessary.

10. Measure the outside diameter of the clutch housing bushing and the inside diameter of the housing and compare the values to the service limits. If either the housing or the bushing are to be replaced, replace the needle bearing as well.

	Standard	Service Limit
Housing inside diameter	1.4567 ~ 1.4573 in. (37.000 ~ 37.016 mm)	1.458 in. (37.03 mm)
Bushing outside diameter	1.2590 ~ 1.2596 in. (31.980 ~ 31.995 mm)	1.258 in. (31.96 mm)

ASSEMBLY

1. Assembly is basically in the reverse order of disassembly. Use a new cover gasket.



2. Keep the clutch hub from rotating as in the disassembly procedure, and secure the hub nut to 87–108 ft lbs (12–15 kg/m). Remember that the correct order is washer-hub-washer-hub nut.

NOTE: *The washer between the clutch hub and the hub nut has "outside" marked on it and must be properly installed.*

3. Install the friction and steel plates, starting with a friction disc and then alternating them.

4. Install the release bearing and pushrod in the driveshaft, then install the pressure plate, springs, washers, and mounting bolts, securing them in a cross pattern. Tighten the bolts to 78–98 in. lbs (0.9–1.1 kg/m).

5. Liberally lubricate the two release gears with cup grease before installing them. The release lever should be positioned as illustrated.

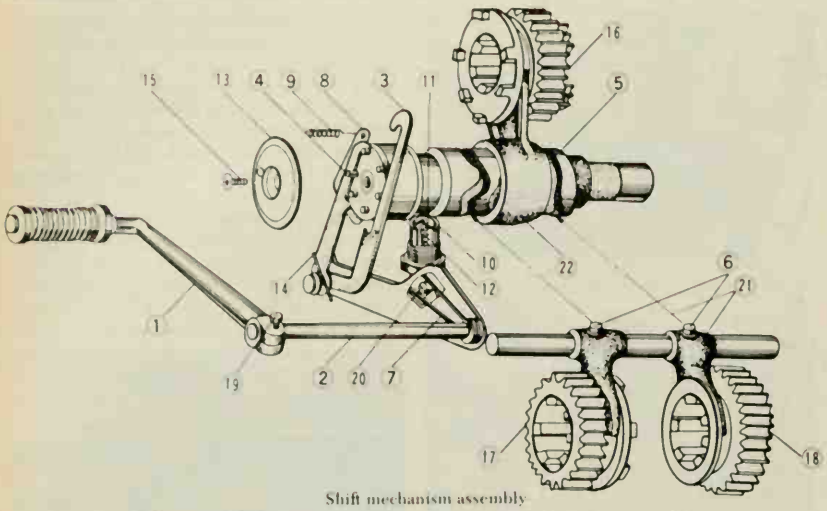
The release lever should be positioned like this

6. Secure the outer gear mounting after applying Loctite® or a suitable thread sealer, to the threads.

7. Refill the engine with oil.

External Shift Mechanism

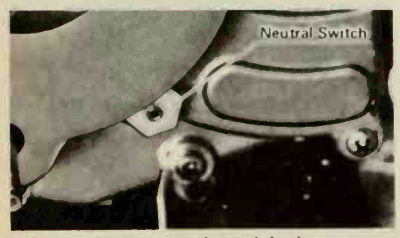
Operating the shift pedal (1) rotates the shifter shaft (2), causing the shift pawl (3) to catch on the appropriate shift drum pin (4), and this rotates the shift drum (5). Each shift fork pin (6) rides in a groove cut in the drum, so that as the drum turns the forks (21 and 22) are forced to move to the right or left as they follow the groove, causing the sliding transmission gears to move in and out of mesh. When the shift pedal is released after the next gear has been selected, the return spring (7) returns the pedal to its original position. A detent arm (8), held against the drum pin by the detent spring (9), keeps the drum from rotating which would cause the transmission to pop out of gear. A Neutral detent pin (11), fitted inside the shift drum positioning pin (10), and acted on by a spring (12), drops into the drum positioning groove when the drum is rotated into the Neutral position.



Worn or broken parts could allow the shift drum to turn randomly, resulting in damage to the transmission and engine (through overrevving). A transmission which will not shift can often be traced to a damaged return spring, shift pawl, or pawl spring, and a tired or broken detent arm spring can cause a transmission to stick in gear or pop out of gear under power.

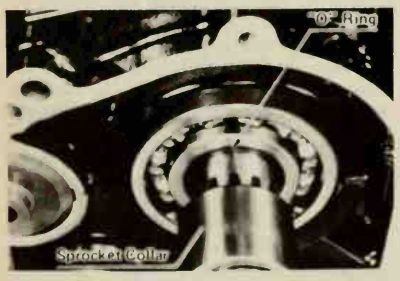
REMOVAL

1. Remove the chain cover and drivesprocket as described in the "Final Drive" Section of the "Chassis" section.



2. Disconnect the Neutral switch lead.

3. Remove the transmission cover, cover gasket, sprocket distance collar, and O-ring. A



Shift mechanism assembly

19. Bolt
20. Return spring pin
21. Shift fork
22. Shift fork

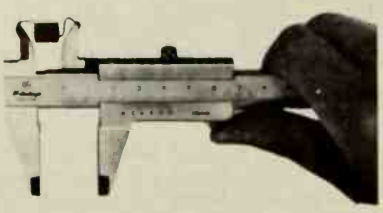
Disconnecting the neutral switch lead

bearing puller may be used if the collar proves difficult to remove.

4. Remove the shift lever assembly and detent lever mounting bolt, then unhook the spring and remove the lever.

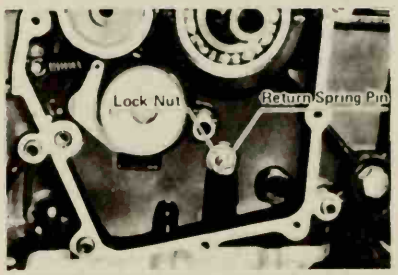
INSPECTION

1. Clean all parts other than gaskets and O-rings in a suitable solvent, then blow them dry.



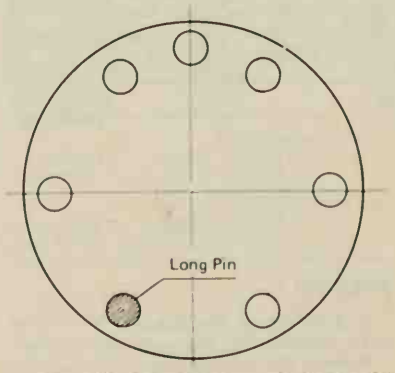
2. Inspect the shift lever spring, shift pawls, pawl spring, and detent arm spring for signs of wear or damage, and replace them as necessary.

3. Measure the free length of the detent arm spring using vernier calipers, and replace it if it is longer than the service limits given below:

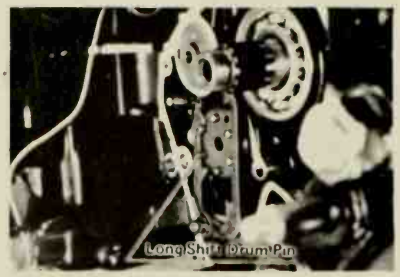


Standard	Service Limit
0.917 in. (23.3 mm)	0.984 in. (25.0 mm)

INSTALLATION

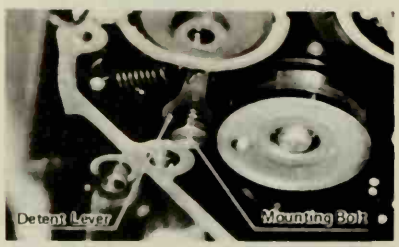


1. Check the return spring pin for a tight fit, and remove it and coat the threads with Loctite before installing it if it was loose.



Measuring the return spring free length

Make sure that the return spring pin is secure

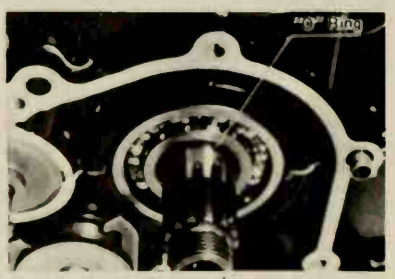


Correct positioning of the long pin is essential

Long pin installed

2. Make sure that the longest shift drum pin is in the position illustrated, if the pins were removed. Failure to properly position the long pin will keep the Neutral light from operating correctly.

3. Install the detent lever taking care to position it so that it rides on the shoulder of its mounting bolt, and so that it doesn't get caught between the bolt and crankcase.



The detent lever must be able to move freely

4. Install a new O-ring behind the sprocket to prevent oil leakage.

5. Use an oil seal guide (Part No. 57001-130) or a suitable substitute while installing the transmission cover so that the shift shaft seal isn't damaged.

6. Install the sprocket collar after the transmission cover is installed to avoid damaging the output shaft oil seal.

7. Grease the pushrod before installing it.

Always use a new O-ring to be sure

Protecting the seal will pay off

LOWER END AND TRANSMISSION

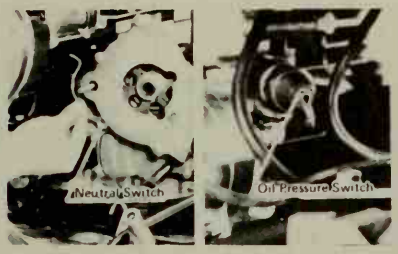
Splitting the Crankcases

DISASSEMBLY

1. Remove the engine from the frame as described in the "Engine Removal and Installation" Section.

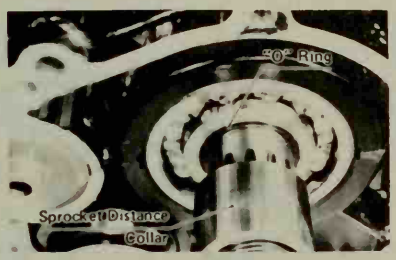
2. Remove the kickstarter pedal, spring cover, and cover gasket, then pull out the spring guide and unhook and remove the spring.

Removing the kick starter spring



3. Remove the clutch hub as described in the "Clutch" Section only if the clutch housing or ball bearing is to be removed from the driveshaft..

4. Remove the contact breaker cover, breaker plate assembly, and advance mechanism as described in the "Electrical System" section, then remove the right-side engine cover.



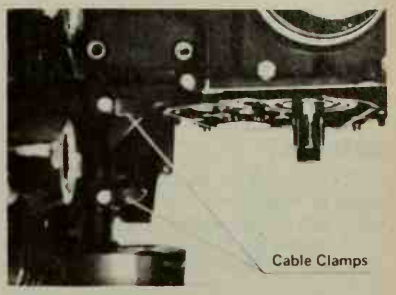
5. Disconnect the leads from the Neutral light switch and the oil pressure switch.

6. Remove the dynamo wires from the clamps, then remove the dynamo cover and cover gasket.

7. Remove the transmission cover and cover gasket, then remove the sprocket distance dollar and O-ring. A bearing puller may be used to remove the collar if necessary.

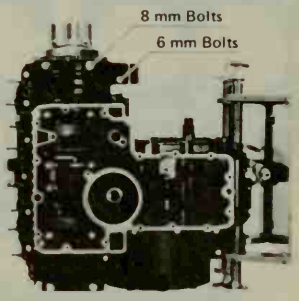
Disconnecting the switch leads

8. Remove the shift lever assembly.



9. Remove the starter assembly.

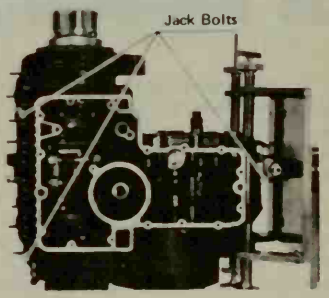
10. Remove the 5 crankcase bolts from the top side of the crankcase. The two cable clamps will also come free, and these should be replaced in their original positions.



11. Invert the engine and remove the oil filter, oil pan, and pan gasket, then remove the oil pump as described in the "Lubrication System" section.

12. Remove the 17 6 mm crankcase bolts (two of which have cable clamps under them and both should be replaced in their original positions), and the 8 8 mm bolts.

CAUTION: *Do not accidentally remove the 4 bolts which hold down the crankshaft.*

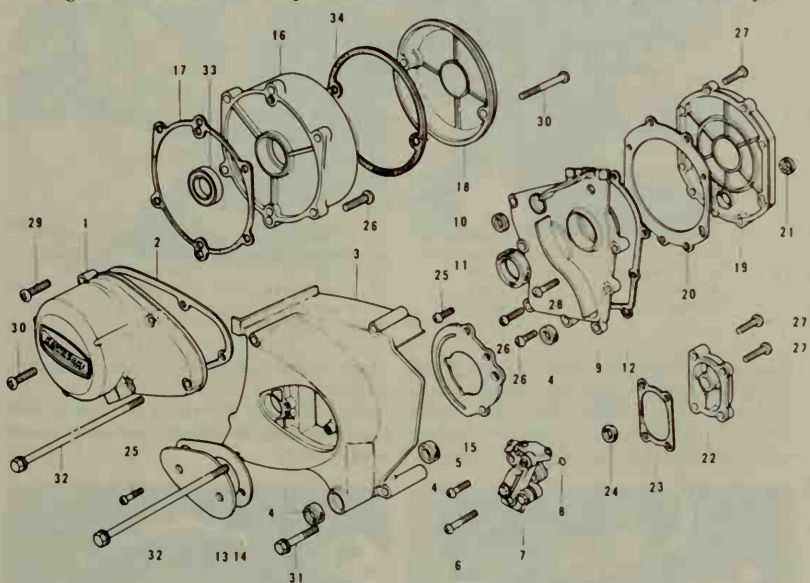


Cable clamp locations

Remove the crankcase bolts evenly

13. Screw 3 8 mm bolts into the jack bolt positions provided in the lower crankcase, and turn them in evenly to separate the crankcase halves. The cases can be gently tapped with a soft mallet to help loosen them.

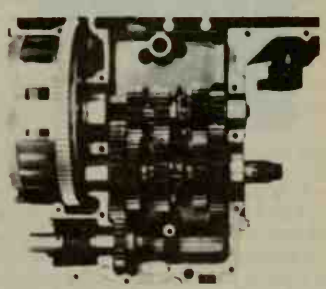
CAUTION: *Do not attempt to pry the cases apart.*



Jack bolt positions

14. Remove the driveshaft, clutch housing, output shaft, and kickstarter shaft.

INSPECTION



1. Clean all metal components in a suitable solvent, then blow them dry taking care to clear all oil passages.

2. Inspect the crankcases, studs, clutch housing, and component systems for signs of wear or damage, and either repair or replace

Engine cover assemblies

1. L.H. engine cover
2. L.H. engine cover gasket
3. Front chain cover

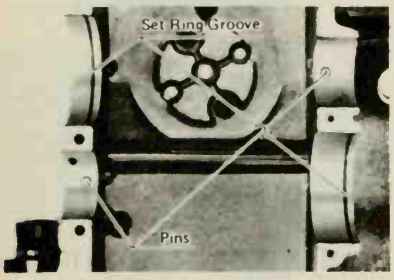
The assemblies ready for removal

them as necessary. For further disassembly procedures for the kick starter, driveshaft, output shaft, shift drum, crankshaft, and cam chain, follow the following "Assembly" Section.

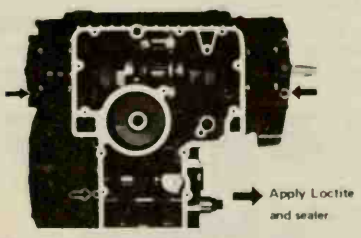


ASSEMBLY

1. Assembly is basically in the reverse order of disassembly. Use all new gaskets, seals, and O-rings wherever applicable.

2. Install the O-ring for the main engine oil passage as illustrated.

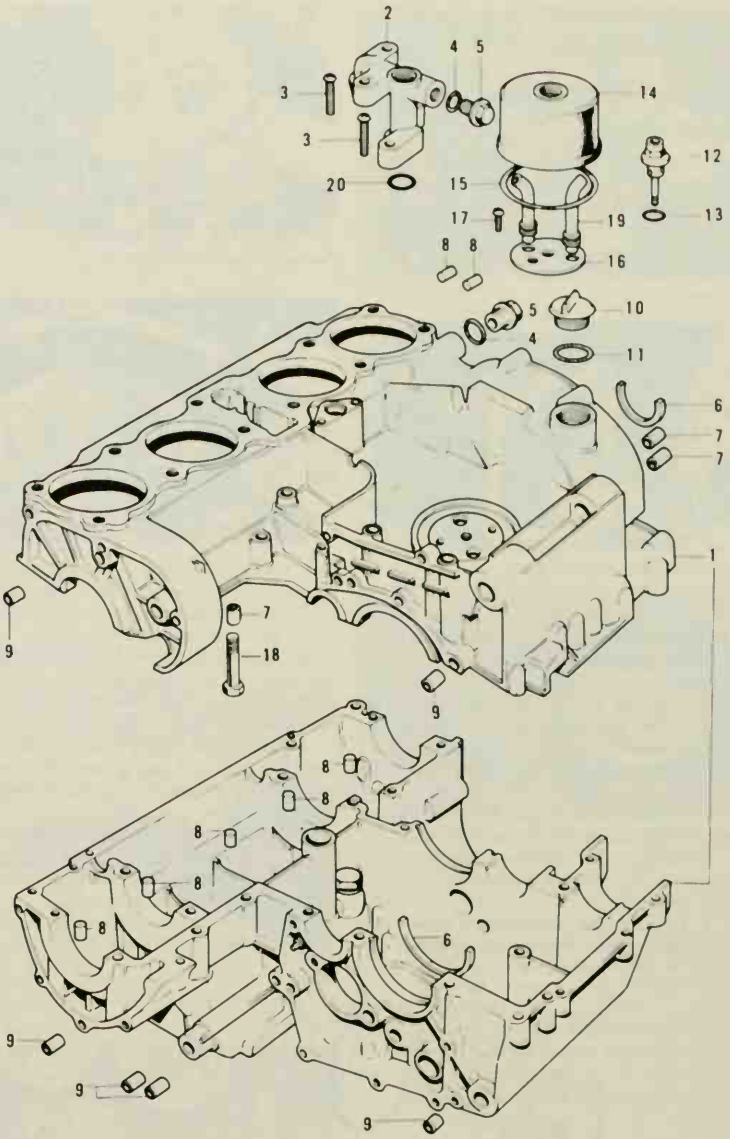
Main oil passage O-ring location



Be sure to install all the pins

3. When installing the output, drive, and kick starter shafts, the crankcase set pins must go into the holes in the respective bushings on the shafts, and the set ring for each ball bearing must be fit into its groove.

4. Thoroughly clean the crankcase mating surfaces, and apply a liquid gasket compound to the surface of the lower case half. Be careful not to use so much compound that it runs down into the crankcase after the halves are joined.

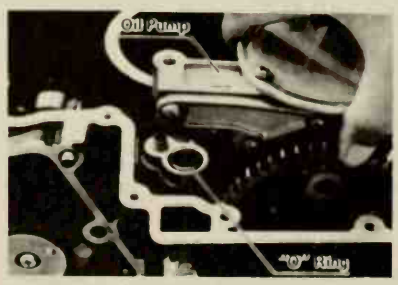


5. Secure the 8 8 mm bolts to 18 ft lbs (2.5 kg/m) torque, evenly following the order numbers on the lower case half. The threads of bolts 6 and 8 should be *coated with Loctite, and* #1 sealer (the hardening type) should be applied to the underside of the bolt heads.

Bolts which must be sealed

6. Secure the 22 6 mm bolts to 70 in. lbs (0.8 kg/m). Coat the threads of the remaining bolt depicted in the accompanying illustration with Loctite, and apply #1 sealer (the hardening type) to the underside of the bolt head.

7. Install the O-ring depicted in the accompanying illustration, and check that the oil pump gear meshes correctly with the crankshaft gear when installing the pump. Apply Loctite to the pump mounting bolts, and secure them to 70 in. lbs (0.8 kg/m) torque.



Crankcase assembly

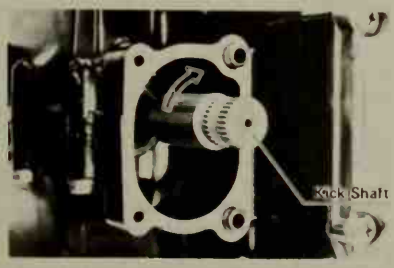
14. Bolt, hex head, 6 x 54
15. Bolt, hex head, 6 x 94
16. Bolt, hex head, 6 x 72

Crankcase bolt and stud locations

10. Use either the factory oil seal guide (Part No. 57001-130), or a suitable substitute, to protect the oil seal while installing the transmission cover, and install the sprocket distance collar after the cover is in place, otherwise the seal will be damaged.



Installing the transmission cover

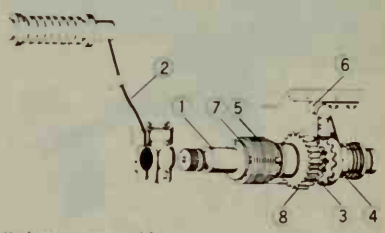
11. Apply Loctite to the 3 upper right engine cover mounting screws.

12. Align the pin and groove when installing the advance mechanism.

13. Rotate the kickstarter shaft all the way to the right before hooking the spring into the hole in the shaft.

The kickstarter must be preloaded before the spring is installed

14. Mount and secure the kick starter cover, using either the factory oil seal guide (Part No. 57001-131) or a suitable substitute, to protect the oil seal.



Installing the kick starter cover

Kick Starter

The kick gear ⑧ which is constructed with a ratchet on one side, is always meshed with 1st gear of the output shaft, and turns freely any time the output shaft is turning. The kick shaft ① is splined, and a ratchet gear ③ mounted on this shaft is pushed toward the kick gear by a spring ④. When no kicking is being done, however, the lever on the ratchet gear hits a stopper ⑥, and the ratchet gear is prevented from meshing with the kick gear ratchet.

When the pedal ② is kicked, the lever moves out from behind the stopper and the ratchet gear meshes with the kick gear ratchet. The kick gear then turns, turning the output shaft 1st gear which turns the crankshaft over via the driveshaft 1st gear and the clutch gear, and starts the engine.

When the kick pedal ② is released, the kick spring ⑤ returns the pedal to its original position. As the pedal returns, the ratchet gear lever (and the ratchet gear) is guided away from the kick gear by the stopper, and the ratchet gear returns to its rest position.

Kick starter assembly

1. Kick shaft
2. Kick pedal
3. Ratchet gear
4. Spring
5. Kick spring
6. Stopper
7. Spring guide
8. Kick gear

If the kick pedal return spring weakens or breaks, the kick pedal will not return completely or at all, and the ratchets will stay partially meshed and make noise while the engine is running. Kick mechanism noise may also occur when the kick gear bushing or kick shaft becomes worn.

If the teeth of either ratchet are worn or damaged, the ratchet will slip and it will be impossible to kickstart the engine.

DISASSEMBLY

1. Remove the engine from the frame, and separate the crankcases as described previously.

2. Remove the circlip (1), cap (2), coil spring (3), ratchet (4), circlips (1), washer (5), kick gear (6), washer (7), and bushing (8) from the kick shaft (10).

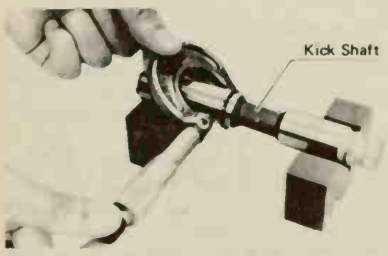
INSPECTION

1. Clean all parts in a suitable solvent, then blow them dry.

2. If the kick starter made a ratcheting noise while the engine was running, check the pedal return spring and the kick gear bushing and shaft for wear. Wear on these parts, and damage to the kick gear teeth are the most common kick starter problems. If any of these parts appear worn, pitted, collapsed (in the case of the spring), or damaged, they should be replaced. The ratcheting gears should be replaced as a set if either is damaged, as indicated by slipping of the kick starter pedal.

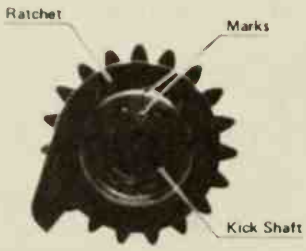
3. Measure the inside diameter of the kick gear, and replace it if it is worn past its service limit given below:

Standard	*Service Limit*
0.8653 ~ 0.8661 in. (21.979 ~ 22.000 mm)	0.8681 in. (22.05 mm)



4. Measure the outside diameter of the kick start shaft, and replace it if it is worn past its service limit given below:

Standard	*Service Limit*
0.8637 ~ 0.8646 in. (21.939 ~ 21.960 mm)	0.8626 in. (21.91 mm)



ASSEMBLY

1. Assembly is basically in the reverse order of disassembly. The oil seal (13) should be replaced.

2. When the ratchet is assembled to the kick shaft, align the mark on the ratchet with the mark on the shaft.

Measuring the diameter of the shaft

These marks must be alignment

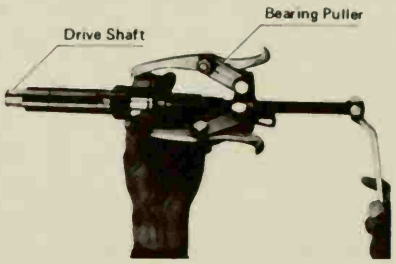
Transmission

A 5-speed, constant mesh, return-shift type transmission, housed in the crankcases, is used on these models to put the power on the ground. The driveshaft runs off the clutch, and drives the output shaft which drives the chain which drives the rear wheel.

The 3 shift forks ride on gears D3 ("D" means Driveshaft, "O" means Output shaft, and the number indicates which gear), O4, and O5, and can move them along the shaft, although each gear must rotate with its shaft. Gears D1 and D2 are fixed to the driveshaft; gears D4, D5, O1, O2, and O3 are free to rotate on the shaft, but cannot move along the shaft.

Inside gear O4, 3 steel balls are located 120° apart, and serve to facilitate Neutral location when shifting from 1st gear. When the motorcycle is stopped and the output shaft is not turning, one or two of these balls falls down into its respective groove in the output shaft. When the shift pedal is operated to shift from First toward Second, gear O4 starts moving, but halfway toward its Second gear position, the steel ball(s) hits the end of the groove(s) in the output shaft, stopping gear O4 from moving, stopping the shift drum from turning, and leaving the transmission gears in the Neutral position.

Trouble in shifting could be caused by wear of the shift forks, the shift fork grooves in the gears, shift fork guide pins, or the grooves in the shift drum. It could also be the result of bent shift forks, or of damage to the tongues on the side of the gears or the holes that they go into. If there is trouble in the external shift mechanism or with the clutch release, this could also cause difficulty in shifting.



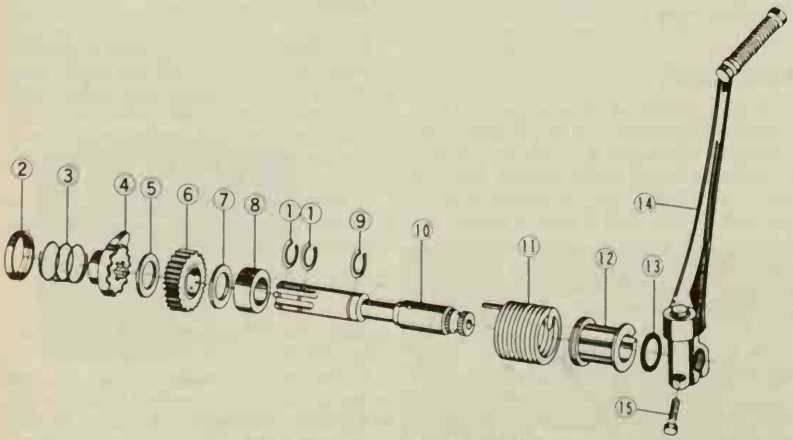
Transmission noise will result from gear teeth damage, or damage or wear of the gear bushings, shaft, bearings, etc.

DISASSEMBLY

1. Remove the engine from the frame, and separate the crankcases as described previously. Before removing the gear clusters from the crankcase, the gears should be checked for backlash. Consult the "Inspection" Section for additional information.

2. Remove the bushing (1), circlip (2), shim (3), needle bearing (4), washers (5 and 6), Second gear (7), Fifth gear (8), Fifth gear bushing (9), and the toothed washer (10).

3. Remove the retaining ring (11), Third gear (12), the next retaining ring (11), the toothed washer (10), and Fourth gear (13), then pull the bearing (14) with a suitable bearing puller.



Drive shaft bearing removal

4. Remove the bushing (15), retaining ring (2), shim (3), needle bearing (4), washers (5 and 6), First gear (16), and shim (17).

5. Rotate the shaft while removing the Fourth gear (29) so that the 3 balls (30) will move, then pull the bearing (18) from the shaft using a suitable bearing puller, and remove the washer (19), Second gear (20), the Second gear bushing (21), and the toothed washer (22) from the shaft.

6. Remove the circlip (23), Fifth gear (24), the next circlip (23), the toothed washer (22), Third gear (25), and the washer (26).

15. Clamp bolt

INSPECTION

1. Clean all parts in a suitable solvent, then blow them dry. The oil seal (35) which has already been removed during the initial disassembly procedure, should be replaced. Bearings should be washed with clean gasoline, blown dry, and lubricated with clean oil. DO NOT SPIN UNLUBRICATED BEARINGS.

2. Inspect all parts for signs of wear, damage, pitting, or chipped gear teeth, and replace them as necessary. Gears with chipped or damaged teeth, dogs, or dog holes should be replaced as gear systems rather than as individuals since they act upon one another.

3. Check for excessive gear backlash in all 5 gears by holding one gear steady while rotating the gear it meshes with back and forth. A dial indicator set against the gear which is moved will provide the necessary information. The difference between the highest and lowest reading is the backlash. In cases where the backlash exceeds the limits given below, replace both gears:

900

	Standard	Service Limit
1st gear	0.0008 ~ 0.0075 in. (0.02 ~ 0.19 mm)	0.0098 in. (0.25 mm)
2nd–5th gears	0.0024 ~ 0.0091 in. (0.06 ~ 0.23 mm)	0.0118 in. (0.30 mm)

1000

	Standard	Service Limit
All gears	0.0024 ~ 0.0091 in. (0.06 ~ 0.23 mm)	0.0118 in. (0.30 mm)

4. Measure the inside diameter of each gear, then measure the outside diameter of the shafts, subtract the two, and replace any gear which exceeds the service limits given below:

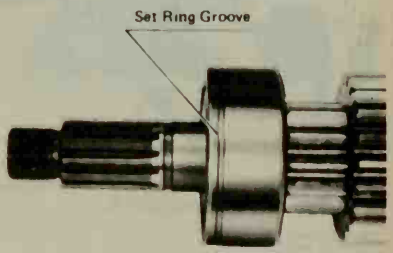
Measuring gear backlash

5. Inspect the bearings for signs of external damage, and spin them (ONLY WHEN LUBRICATED) to check for rough motion or noisy operation, and replace them as necessary.

6. Inspect all the assorted hardware, and replace any circlips which are twisted, or any washers which are worn or scored.

900

Gear	Standard	Service Limit
Drive 4th, output 3rd	0.0008 ~ 0.0024 in. (0.020 ~ 0.062 mm)	0.0064 in. (0.162 mm)
Drive 5th	0.0063 ~ 0.0096 in. (0.160 ~ 0.245 mm)	0.0136 in. (0.345 mm)
Output 1st	0.0011 ~ 0.0024 in. (0.027 ~ 0.061 mm)	0.0063 in. (0.161 mm)
Output 2nd	0.0118 ~ 0.0182 in. (0.300 ~ 0.463 mm)	0.0222 in. (0.563 mm)



1000

	Standard	Service Limit
Output 1st	0.0011 ~ 0.0024 in. (0.027 ~ 0.061 mm)	0.0063 in. (0.16 mm)
Output 2nd, Drive 5th	0.0010 ~ 0.0030 in. (0.025 ~ 0.075 mm)	0.0067 in. (0.17 mm)
Output 3rd, Drive 4th	0.0008 ~ 0.0024 in. (0.020 ~ 0.062 mm)	0.0063 in. (0.16 mm)

ASSEMBLY

1. Assembly is basically in the reverse order of disassembly. Use plenty of fresh motor oil as an assembly lubricant.

2. Press on the ball bearings so that the set ring groove is toward the end of the shaft.

The set ring groove should be toward the end of the shaft

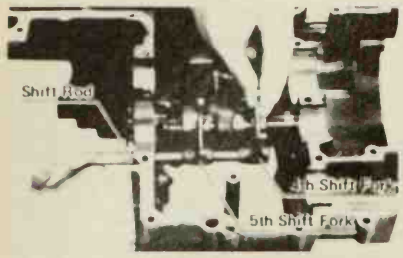
3. Make sure that the Third and Fifth gear driveshaft bushing oil holes ae aligned with the holes in the shaft.

4. Make sure that the Second and Fifth gear (output shaft) oil holes ae aligned with the holes in the shaft.

5. Do not grease the Fourth gear steel balls (30) during assembly, as the balls must be able to move freely.

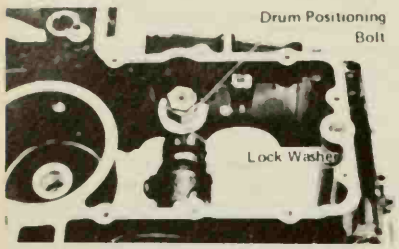
Shift Mechanism

DISASSEMBLY



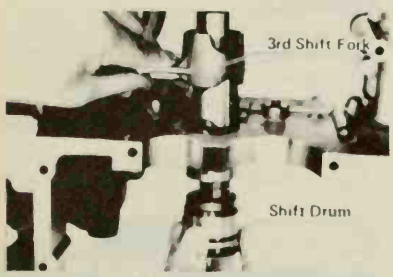
NOTE: *Consult the "External Shift Mechanism" Section for an operational description and illustration.*

1. Remove the engine from the frame, and separate the crankcases as described previously.



2. Tap the shift rod from the clutch end and pull it out, then remove the two (Fourth and Fifth gear) shift forks.

3. Remove the detent arm, bend back the locking tab of the lockwasher, and remove the shift fork pin.

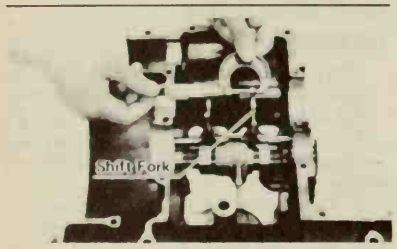


4. Bend back the locking tab of the lockwasher, then unscrew and remove the drum positioning bolt. The cap bolt need not be removed from the top of the positioning bolt.

Removing the shift rod and forks

Remove the positioning bolt, but do not loosen the cap bolt

Removing the shift drum



5. Pull the shift drum out of the crankcase along with the third gear shift fork.

INSPECTION

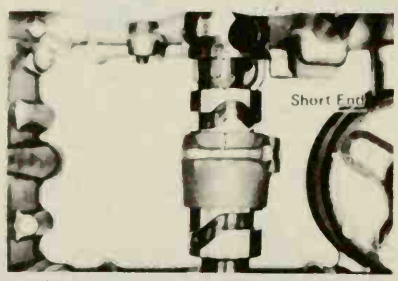
1. Clean all parts in a suitable solvent, then blow them dry.

2. Inspect the shift forks for a worn, pitted, bent, or damaged condition, and replace them as necessary. A bent fork will allow the transmission to pop out of gear under power. If the thickness of the shift fork prongs is less than the service limit listed below, the fork will have to be replaced.

Standard	Service Limit
0.228 ~ 0.236 in. (5.80 ~ 6.00 mm)	0.224 in. (5.70 mm)

Measuring the shifter forks

3. Inspect the shift drum for signs of wear or damage, and replace it as necessary. Compare it to a new one if possible. Measure the width of the shift fork grooves, and replace the drum if worn past the service limits given below:



Standard	Service Limit
0.238 ~ 0.242 in. (6.05 ~ 6.15 mm)	0.246 in. (6.25 mm)

ASSEMBLY

1. Assembly is basically in the reverse order of disassembly.

2. Rotate the shift drum to the Neutral position when installing the drum positioning bolt. The bolt should be coated with Loctite and torqued to 44–57 ft lbs (6.0–8.0 kg/m).

3. The Third gear shift fork is different from the other two, and should be installed so that the short end goes on the drum first, and so that it faces the Neutral switch.

Install the third gear shift fork with the short end as shown

Crankshaft and Cam Chain

REMOVAL

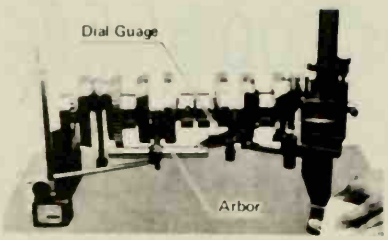
1. Remove the engine from the frame, and separate the crankcases as described previously.

The crankshaft assembly ready to go

2. Remove the crankshaft bearing cap, lift the crankshaft out of the upper case half, and slip the cam chain from it.

3. The crankshaft end bearings may now be removed by using a suitable puller.

INSPECTION

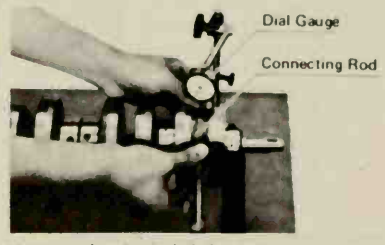


1. Clean the assembly in a suitable solvent, then blow it dry, taking care to clear any oil passages. Lubricate the assembly with fresh motor oil before attempting to spin the bearings.

2. Remove the bearing from each end of the crank, and place it in a V-block. Place a suitable arbor into the connecting rod small end, and measure the difference in height over a 100 mm (4 in.) length, using a dial indicator, to determine the amount which a connecting rod is bent. The standard for this is under 0.002 in./100 mm (under 0.05 mm/100 mm), and the crankshaft assembly should be replaced if the measurement is over the service limit of 0.008 in. (0.20 mm).

3. Use the method described above to determine whether or not a rod is twisted by

Checking the rods for a bent condition



Checking the rods for a twisted condition

checking the amount in which the arbor varies from parallel over a 100 mm length of arbor. The standard for this is the same as that given in the previous step.

4. Check for big end radial clearance by setting the crank, with the end bearings removed, in V-blocks with a dial indicator set against the connecting rod to be checked. Push the rod against the gauge, and then pull it away. The difference between the two readings is the radial clearance. If the clearance for any of the rods exceeds the service limit listed below, the crankshaft will have to be replaced.

Standard	Service Limit
0.0006 ~ 0.0012 in. (0.016 ~ 0.030 mm)	0.0031 in. (0.08 mm)

Measuring bearing radial clearance

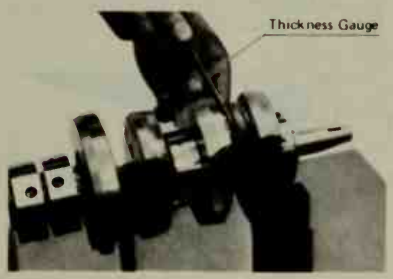
5. Measure the connecting rod side clearance using a thickness gauge as shown in the illustration. If the clearance on any of the connecting rods exceeds the service limits given below, the crankshaft will have to be replaced.

Standard	Service Limit
0.012 ~ 0.016 in. (0.3 ~ 0.4 mm)	0.024 in. (0.6 mm)

6. With the end bearings removed and the crankshaft in that old V-block set up once again, rotate the crank slowly with a dial indicator set against each of the bearings in order. The difference between the highest and lowest reading is the runout. The crankshaft must be replaced if the run-out exceeds the service limit given below:

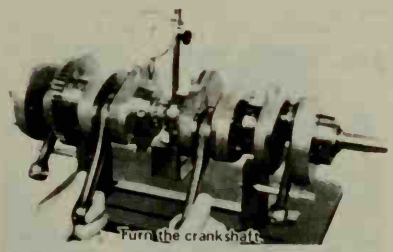
Standard	Service Limit
under 0.0012 in. (under 0.03 mm)	0.004 in. (0.10 mm)

7. Clean the bearings with clean gasoline, blow them dry, then lubricate them with fresh motor oil. DO NOT SPIN UNLUBRICATED BEARINGS. Spin the bearings by hand and check for smooth motion and quiet operation. If the bearings are noisy or rough they must be replaced. Only the end bearings can be replaced without a major crankshaft rebuild.



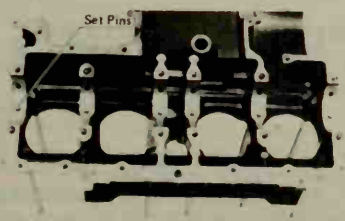
8. Inspect the bearing cap for signs of wear or damage. Since it is machined along with the crankcase, it must be replaced in conjunction with the crankcase if it is damaged.

INSTALLATION

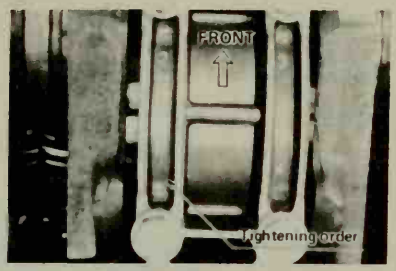


1. Installation is in the reverse order of removal.

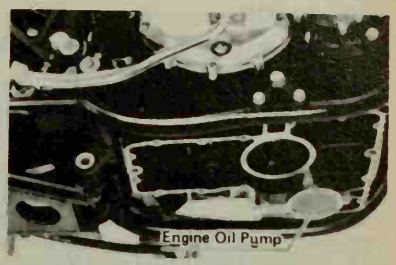
2. Align each pin in the upper crankcase with the pin hole in each bearing before slipping the crankshaft into place.



3. The crankshaft bearing cap is bored along with the crankcase, so that it must be installed with the arrow pointing toward the front of the engine. Secure the bolts with 18 ft lbs (2.5 kg/m) torque in the numbered sequence.



Measuring bearing side clearance



Measuring crankshaft run-out

Engine with oil pan removed

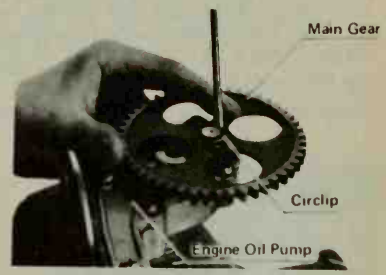
LUBRICATION SYSTEMS

ENGINE LUBRICATION

Oil Pump

REMOVAL AND DISASSEMBLY

1. Drain the engine oil and remove the filter.

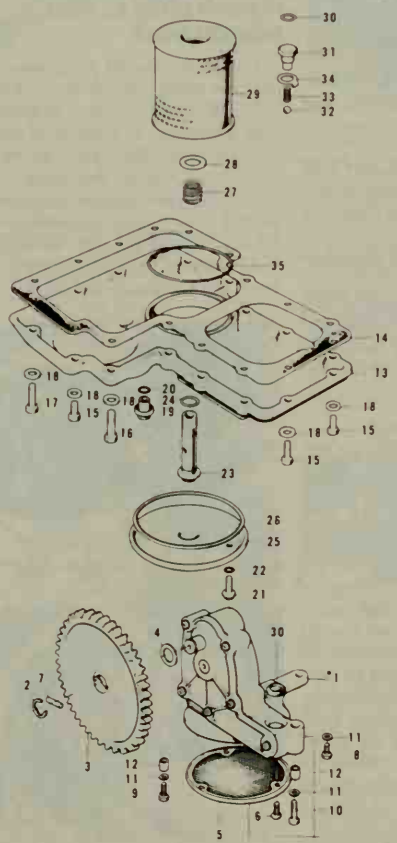


2. Remove the exhaust system.

3. Remove the bolts which secure the oil pan, then remove the oil pan and gasket.

4. Remove the bolts which secure the oil pump, then remove the oil pump.

5. Secure the pump in a wood-jawed vise, or take precautions to avoid deforming the pump body, then remove the circlip, main gear, alignment pin, and shim.



6. Remove the screws which secure the pump housing halves together, then gently tap the two shafts alternately until the halves can be separated without damaging the shafts.

Removing the circlip and main gear

Separating the pump body halves

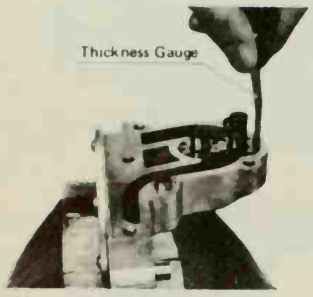
34. Lock washer
35. O-ring



Lubrication system assembly

INSPECTION

1. Clean the pump components thoroughly in a suitable solvent, then blow them dry.

2. Inspect all parts for a worn or damaged condition, and replace them as necessary. All gaskets and O-rings should be replaced as a matter of course.

3. Assemble the two internal gears in one side of the pump body, and check the clearance between each gear and the pump body with feeler gauges. The standard clearance on 900 models is 0.0001–0.0014 in. (0.003–0.036 mm), and the pump must be replaced if it is worn past its serviceable limit of 0.004 in. (0.10 mm). On the 1000, standard clearance is 0.0004–0.0033 in. (0.011–0.083 mm), the service limit being 0.006 in. (0.14 mm).

Checking gear/pump body clearance

4. Inspect the strainer screen for a damaged, worn, or permanently clogged condition, and replace it as necessary.

ASSEMBLY AND INSTALLATION

1. Assembly is in the reverse order of disassembly, and installation is in the reverse order of removal.

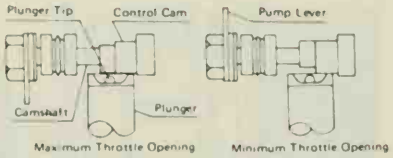
2. Make sure that the gasket surface of both pump body halves is in perfect condition, and is absolutely clean, and always use a new gasket during assembly.

3. Use Loctite®, or a suitable thread sealing compound, on all of the assembling screws and mounting bolts, and torque the mounting bolts to 70 in. lbs (0.8 kg/m).

4. Make sure that the pump and crankshaft gears mesh properly.

5. Make sure that the sump pan gasket surfaces are perfectly clean, use a new pan gasket, and tighten the pan securing bolts in a crossed sequence to avoid deforming the gasket.

Oil Pressure Switch



For information on oil pressure switch repair and troubleshooting, consult the "Electrical System" Chapter.

Drive Chain Oil Pump

OPERATIONAL DESCRIPTION

An output (countershaft) shaft-drive, plunger-type oil pump is fitted on the Z1 (1973–74 models) to provide lubrication for the drive chain. Oil flow is regulated by both the pump cam setting (which can be manually adjusted for rate of flow) and by engine rpm, since the output shaft drives both the pump and the rear wheel simultaneously. When the pump lever is adjusted for minimum (0 on a scale from 0–5) flow, the length of plunger travel is also at a minimum, and vice versa.

Oil for the pump is contained in a separate

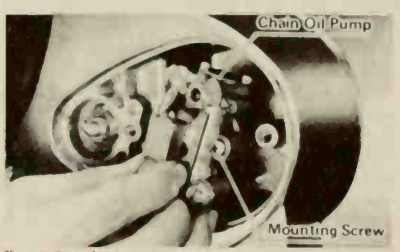
Pump adjustment

chain oiler tank located under the seat, and is gravity fed to the pump through a hose. A non-return check valve is mounted on the output side of the pump, and the oil flows through the hollow pump shaft to the output shaft where it exits through drillings near the drive sprocket. As the output shaft rotates, the oil is flung onto the chain. The accompanying illustration shows the details of the pump's operation. Oil flows into the pump at point A, and along passage B into chamber C. When the plunger moves toward the camshaft on its intake stroke, some space (F) is left between the plunger follower and the cylinder wall. At this time the follower is so positioned that passage D in the follower is aligned with a hole in the valve sleeve, and the oil flows from chamber C through passage D through space E into the empty area F. As the plunger returns on its pumping stroke it rotates back to its original position, causing passage G to be aligned with the outlet hole in the sleeve instead of D being aligned with the inlet hole, and the plunger's motion decreases area F causing the oil to flow into the check valve inlet H. The pressure exerted by the oil presses the ball back, compressing the check valve spring, and allowing the oil to flow through the valve and eventually to the chain.

PUMP REMOVAL AND DISASSEMBLY

1. Remove the oil pump cover, slide back the hose clamp, and disconnect the hose.

NOTE: *Insert the cover screw into the hose, as illustrated, to prevent oil leakage.*



2. Remove the two pump mounting screws, and remove the pump.

3. Wrap cloth around the pump shaft (1) to protect it, then pull it out with pliers. A spacer (2) should come out with the shaft.

4. Remove the shaft bushing (5), then remove the O-ring (3) and oil seal (4).

Pliers can be used to stop flow until a screw is inserted

Removing the pump

5. Remove the cap screws and top cap (6), then remove the plunger spring (7), plunger guide stopper (8), and O-ring (9).

6. Remove the cap screws and bottom cap (10), then remove the O-ring (11).

7. Gently press on the bottom of the plunger (14) with a thin rod to remove the top plunger (13), guide (12), and bottom plunger (14) from the pump body (17).

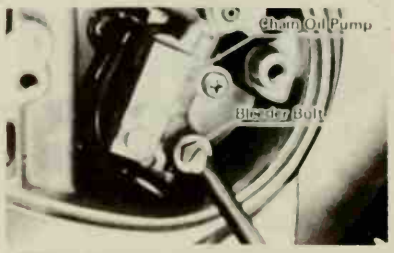
8. Remove the control cam (15) and V-ring (16).

9. Remove the banjo bolt (18) and banjo assembly, and the check valve securing bolt (29) and check valve housing (30).

INSPECTION

1. Clean all but the rubber parts in a suitable solvent, then blow all but the check valve assembly dry.

CAUTION: *The pressure exerted by compressed air may damage the check valve.*



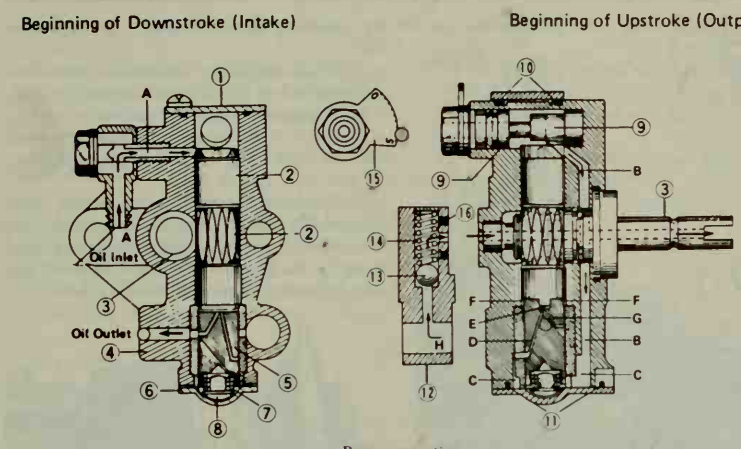
2. Inspect all parts for a worn or damaged condition. The O-rings and the check valve are the only parts which are expected to wear, and consequently are the only available replacement components available. If other parts are worn or damaged, the entire pump assembly should be replaced.

3. Check that the check valve will pass oil in only one direction, and that it isn't clogged. The valve can be easily cleaned with gasoline or solvent in a syringe.

4. Whenever the pump is disassembled, or if the pump oil tank runs dry while the pump is in operation, air will enter the pump, which must then be bled. Do this by removing the bleeder bolt (28) until oil starts to run from the hole, then secure the bolt.

Testing the check valve

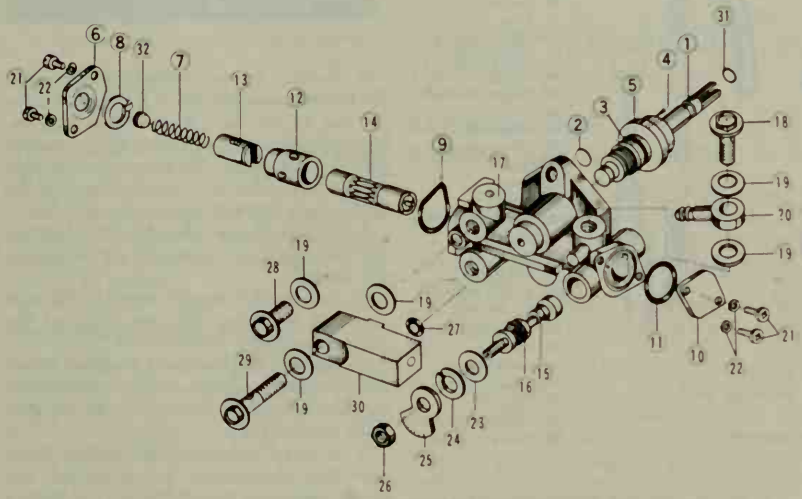
Bleeding the pump



ASSEMBLY AND INSTALLATION

1. Assembly and installation are in the reverse order of removal and disassembly.

2. Lubricate the oil seal with clean oil before pressing it into position.



3. Lubricate the O- and V-rings, plungers, and plunger guide before assembly.

4. Rotate the rear wheel until the pin in the output shaft is brought into alignment with the groove in the oil pump shaft. This is essen-

Pump operation

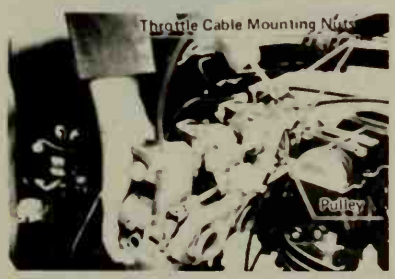
tial for correct installation as otherwise the pump will not seat correctly.

5. Apply Loctite®, or some other suitable thread sealer, to the pump mounting screws before installing them.

6. Bleed the pump as directed in Step 4 of the preceding Section before securing the pump cover.

7. Check the oil level in the chain oiler pump tank.



FUEL SYSTEMS

CARBURETOR OVERHAUL (1973–75)

Carburetor Bank

REMOVAL AND INSTALLATION

1. Disconnect the fuel lines at the gas tank, then remove the tank.

Removing the carburetor bank assembly

2. Loosen the 4 intake manifold clamps at the front, and the 4 air cleaner hose clamps at the back, then pull the carburetor bank off to the rear.

3. Loosen the throttle cable mounting nuts, and disconnect the cables from the pulley.

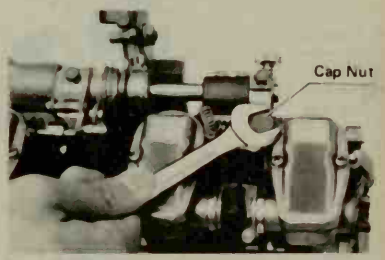
4. Installation is in the reverse order of removal. Note the following:

a. All clamps must be secure enough to prevent air leaks, especially at the intake manifold.

b. Adjust the throttle cables as described in the "Tune-Up" section.

Individual Carburetor

REMOVAL AND INSTALLATION

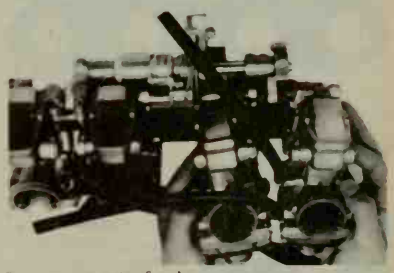


1. Remove the carburetor bank as described in the previous Section.

2. Remove the throttle stop screw locknut (1) from both the carburetor to be removed and its companion, then remove the double washer link (2).

3. Remove the throttle stop screw (53), stop screw spring (54), and the spring seat (4).

Removing the stop screw locknut

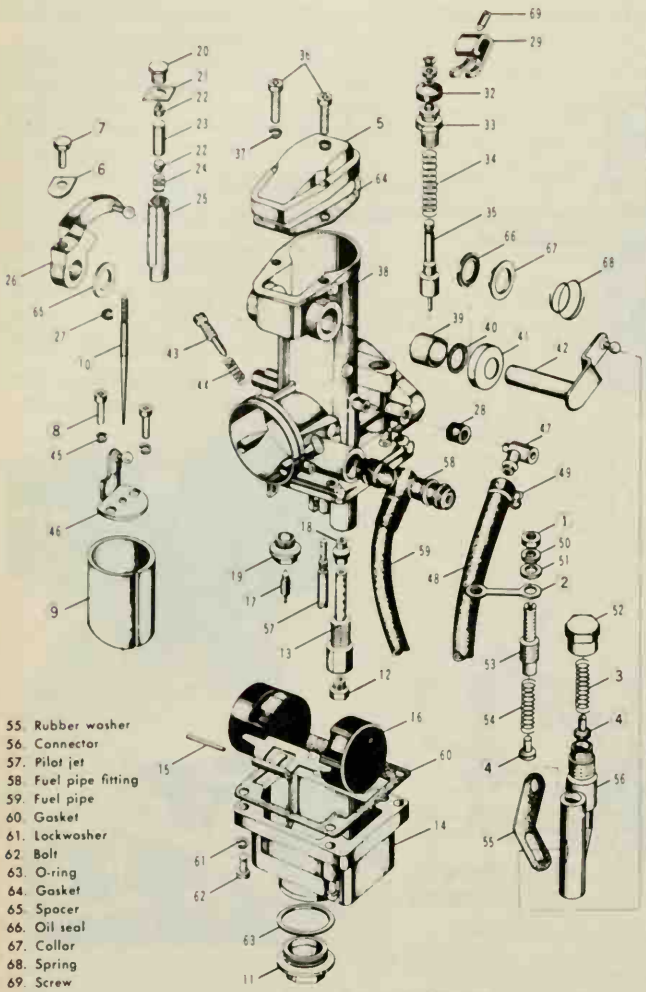


Removing the cap nut

4. Remove the cap nut (32) from the linkage of the carburetor which is to be removed, then remove the spring (3) and seat (4).

CAUTION: *Upon removal of the cap nut the spring may pop out. Be prepared to catch it.*

5. Remove the 4 mounting screws and swing the pair of carburetors you are working with away from the plate. The object of your attentions may now be pulled off to the side.



Removing a pair of carbs

6. Installation is in the reverse order of removal. Use Loctite, or some other suitable sealer, on the mounting screws.

Linkage

DISASSEMBLY AND ASSEMBLY

1. Remove all of the carburetors from the mounting plate as described in the previous Section.

Carburetor assembly

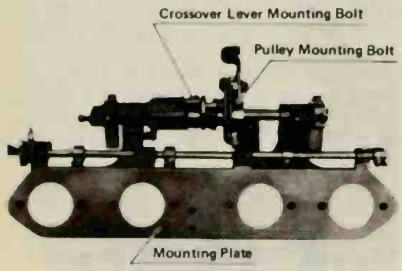
by removing the drain plug (11) and washer (63).

NOTE: *Consult the "Individual Carburetor Removal and Installation" Section for a labeled exploded view illustration.*

2. Remove the top cover mounting screws (36) and washers (37), then remove the cover (5) and cover gasket (64).

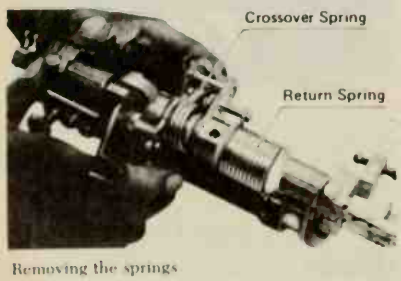
3. Bend flat the lockwasher tab (6), then remove the bolt (7). The lever assembly (42) can now be removed along with its associated components. The connector assembly (56) can now be further disassembled if so desired.

Removing the lever assembly mounting bolt



4. Remove the two screws (8) which secure the bracket assembly (46) to the throttle valve (9), and lift the bracket, complete with the lever assembly (26) and connector assembly (25), out of the bore. The connector assembly may be further broken down by removing the guide screw (20) and components (21–24).

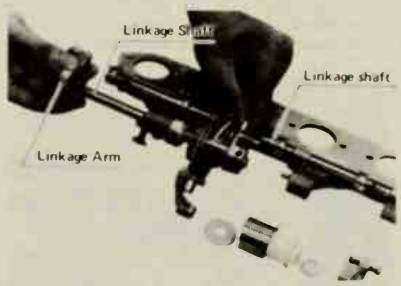
5. Remove the throttle valve (9) and needle (10) from the bore, taking care not to damage the needle.



6. Remove the plunger assembly (35) after removing the lever (29), cap (32), and the guide screw (33).

7. Remove the float bowl securing screws (62), the float bowl (14), the bowl gasket (60), the float (16), float pivot (15), and the float valve needle (17).

8. Remove the main jet (12) and air bleed pipe (13), then invert the carburetor and gently press out the needle jet (18) with a



Mounting plate assembled

Removing the springs

2. Remove the crossover lever and pulley mounting bolts, then unhook the crossover spring from the pulley pin, and the throttle return spring from the crossover lever pin.

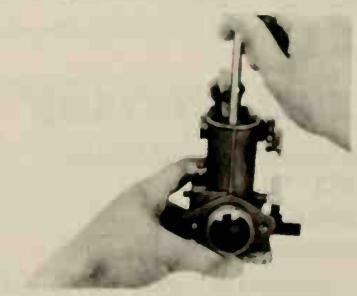
3. Remove the bolt which secures the linkage arm to the shaft from either of the arms,

Removing the linkage shaft

then pull the shaft out from the opposite end. The other arm need not be removed.

NOTE: *The starter (choke) linkage need not be removed unless it is defective.*

4. Assembly is in the reverse order of disassembly. Lubricate the shafts at this time.



Carburetor

DISASSEMBLY

1. Remove the carburetor to be disassembled as described in the "Individual Carburetor Removal and Installation" Section. The fuel may be drained from the float bowl

Removing the throttle valve

Removing the needle jet

wooden rod or some other suitable instrument.

9. Remove the valve seat (19), the pilot jet (57), the pilot air screw (43) and spring (44), and any other remaining items such as the fuel lines and their hardware.

ASSEMBLY

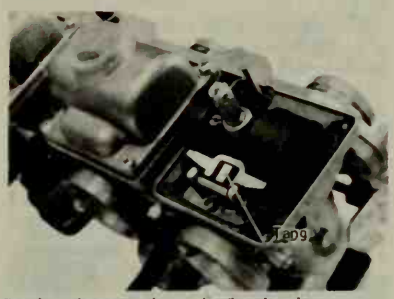
1. Assembly is in the reverse order of disassembly. Use all new gaskets and O-rings.
2. Do not overtighten the jets when installing them in the carburetor body.
3. Make certain that the jet needle is installed in the same position as when it was removed. The clip should be in the third groove from the top on all models except the 1975 (2nd groove from top).

Jet needle clip positions

4. Adjust the height of the float as described in the following Section if necessary, and adjust the carburetor as described in the "Tune-Up" section.

Float Height Adjustment

1. Turn the fuel tap to the "Off" position, remove the overflow vent tube (which will interfere with the knurled knob), and remove the float bowl drain plug. Be prepared to catch the fuel which will run out.
2. Install the fuel level measuring device (Part No. 57001-122 for the Z1, 57001-208 for the KZ900) in place of the drain plug.



NOTE: *The original fuel level gauge hose (Part No. 99990-020) was incorrectly calibrated, and has been subsequently replaced with the part number given in the above Step.*

Special tool installed

3. Hold the plastic tube against the carburetor body and turn the fuel tap to the "On" position. The gas level in the hose should come up to 0.10–0.18 in. (2.5–4.5 mm) below the edge of the carburetor body.
4. If the fuel level is incorrect, the float must be adjusted in the following manner:
   a. Drain the fuel from the float bowl, then remove the bowl. Be prepared to catch the float, float pivot pin, and float needle.
   b. Bend the tang on the float slightly to adjust the float height. Bending the tang up will lower the fuel level, and bending it down will raise it.

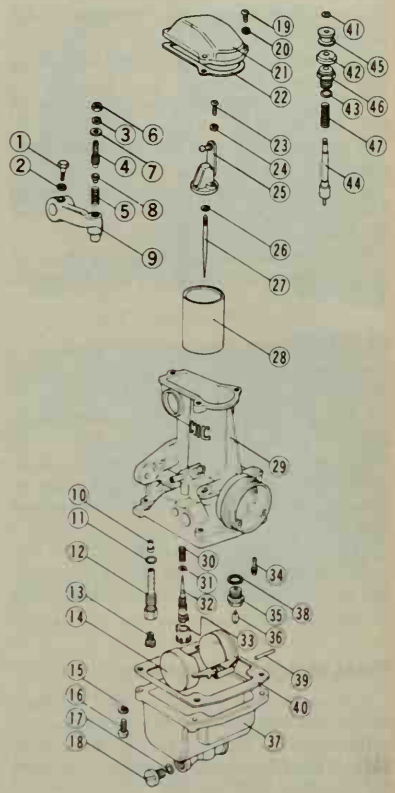
NOTE: *When checking the fuel level of the inside two carburetors, the outside carb base may be used as a reference point for the gauge.*

Bending the tang adjusts the float height

CARBURETOR OVERHAUL (1976–80)

Carburetor Bank

REMOVAL AND INSTALLATION



1. Remove the left and right side covers. Remove the gas tank and tool kit and tray.
2. Loosen the air cleaner duct clamp at each carburetor and remove the duct. Loosen the carburetor clamps.
3. Screw in the throttle cable adjusters as far as possible to yield a maximum of cable play.
4. Loosen the cable adjuster mounting nuts, remove the cables from their brackets and disengage the cables from the pulley.
5. Remove the carburetor air vent tubes from the air cleaner cap and pull them out towards the engine. Pull the carburetor overflow tubes out of their guide.
6. Remove the carburetor assembly.
7. Installation is the reverse of removal. Note the following points:
   a. Be sure that the air cleaner ducts are properly installed. The outer ducts are marked "R" and "L" and "UP" is also marked. Check that the lines on the ducts align with the lines on the holding plate. To position the ducts, first loosen the holding plate screws.
   b. After installing the carburetors onto the engine, check the arrangement of the throttle cables which must run between the frame top tube and the right-side upper cradle tube and must be free of kinks or sharp bends.

Individual Carburetor

REMOVAL AND INSTALLATION

All carburetor parts with the exception of the starter plungers and the fuel line 3-way joint can be removed without removing the carbs from their mounts. If individual removal is required, proceed as follows:

1. Remove the carburetors from the engine as outlined above. Remove the idle screw and spring.
2. Remove the carburetor top covers.
3. Detach the throttle return spring.

Carburetor assembly (KZ1000)

1. Mounting bolt	16. Screw
2. Lockwasher	17. O-ring
3. Lockwasher	18. Drain plug
4. Adjusting screw	19. Screw
5. Spring	20. Lockwasher

12. Air bleed pipe	27. Jet needle
13. Main jet	28. Throttle valve
14. Float	29. Carburetor body
15. Lockwasher	30. Spring

4. Remove the throttle arm mounting bolt from each carb and remove the pulley mounting bolt.
5. Remove the throttle shaft set plate.
6. Remove the rubber cap from each outside carburetor. Push out the throttle shaft.
7. Remove the carburetor mounting screws (2 ea) and take off the individual units.
8. Installation is the reverse of removal. Note the following points:
   a. Use a non-permanent thread-locking compound on the mounting screws.
   b. Grease the throttle shaft before installation.
   c. Perform the initial synchronization sequence as outlined in the "Tune-Up" section.

Carburetor

DISASSEMBLY

1. To remove the throttle valve assembly, first remove the throttle shaft as outlined above under "Individual Carburetor Removal and installation," Steps 1–6.
2. Lift up the linkage and pull out the throttle valve and jet needle.
3. To remove the needle, remove the two

screws which secure the throttle valve bracket.

4. Remove the four screws and take off the float bowl and gasket.

5. Unscrew and remove the pilot screw, O-ring, and spring.

6. Remove the main jet, air bleed pipe, and pilot jet.

7. Push out the float pivot pin. Remove the float and float needle. Unscrew and remove the float valve seat and gasket.

8. To remove the needle jet, push it out from the top of the carburetor with a wooden dowel.

ASSEMBLY

1. Assembly is in the reverse order of disassembly. Use all new gaskets and O-rings.

2. Do not overtighten the jets when installing them in the carburetor body.

3. Make certain that the jet needle is installed in the same position as when it was removed. The clip should be in the third groove from the top.

4. Adjust the height of the float as described in the following Section if necessary, and adjust the carburetor as described in the "Tune-Up" section.

Float Height Adjustment

1. Turn the fuel tap to the "Off" position, remove the overflow vent tube (which will interfere with the knurled knob), and remove the float bowl drain plug. Be prepared to catch the fuel which will run out.

2. Install the fuel level measuring device (Part No. 57001-208) in place of the dain plug.

3. Hold the plastic tube against the carburetor body and turn the fuel tap to the "On" position. The gas level in the hose should come up to 0.10–0.18 (2.5–4.5 mm) below the edge of the carburetor body.

4. If the fuel level is incorrect, the float must be adjusted in the following manner:

a. Drain the fuel from the float bowl, then remove the bowl. Be prepared to catch the float, float pivot pin, and float needle.

b. Bend the tang on the float slightly to adjust the float height. Bending the tang up will lower the fuel level, and bending it down will raise it.

NOTE: *When checking the fuel level of the inside two carburetors, the outside carb base may be used as a reference point for the gauge.*

CARBURETOR OVERHAUL (1981)

Carburetor Bank

REMOVAL AND INSTALLATION

1. Remove the gas tank.

2. Loosen the carburetor clamps on the manifold side.

3. Move the spring bands back from the carb mouths.

4. Disconnect the throttle cable, vacuum lines and feed lines.

5. Pull the carburetors back until free of the manifolds and out to the right side.

6. Installation is the reverse of removal. Note the following points:

a. Route the throttle cable between the right fork leg and the head pipe, and the right side of the frame top tube.

b. Connect the two hoses of the vacuum switch to carbs Nos. 1 and 4. Connect the fuel feed line to carb No. 2.

Carburetor

DISASSEMBLY AND ASSEMBLY

1. Carburetor disassembly is straightforward. Observe the following precautions when working on the carburetors.

2. Take care when removing the throttle slide that the diaphragm is not ripped.

3. The pilot screw is covered with a plug which must be pried off. It is recommended that this item remain in place unless absolutely necessary.

4. The coasting enricher diaphragm cover on the side of the unit has a painted screw in the middle. Do not turn or disturb this screw.

5. When assembling, the pilot screw plug must be held in place with a bonding agent. A new plug should be used.

FUEL TAP

1. Turn the tap to the "Off" position, then disconnect the fuel lines.

2. Remove the tank, or raise and support the back of it.

3. Unscrew the sediment cup on early models and remove the O-ring and strainer.

4. Remove the screw which secures the valve and lever, and remove those parts.

5. The tap may be removed from the tank by loosening the nut or screws which secures it to the tank.

NOTE: *Removing the fuel tap body from the gas tank is not recommended unless replacement is necessary.*

ELECTRICAL SYSTEMS

CHARGING SYSTEM

Alternator

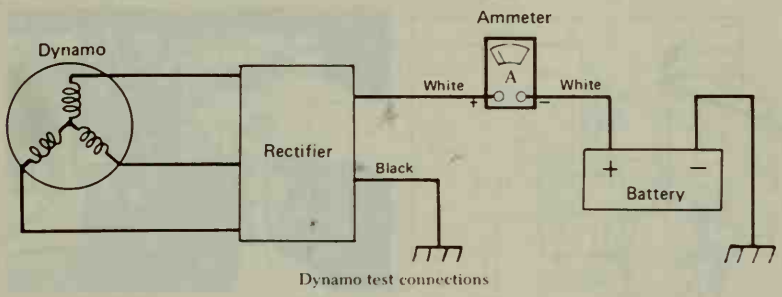
OUTPUT TEST

Before checking the alternator, make sure that the battery, rectifier, and regulator are all good, and be sure that the battery is fully charged. Dynamo failure can be traced to either a short, an open circuit (burned-out wire), or a loss of rotor magnetism.

Test the dynamo in the following manner:

1. Remove the right-side plastic cover, and disconnect the green regulator lead from the connector panel. Be sure that all accessories are turned off.

2. Rotate the hand tester switch to the 30 VDC (from 0–30 volts of DC) scale, and connect it across the battery so that the negative (−) tester lead goes to the negative battery terminal, and the positive (+) tester lead goes to the battery positive terminal.



3. Start the engine and run it at 4000 rpm, taking note of the meter reading. A reading of 15–20 VDC is normal, and a lower reading indicates a defective dynamo.

NOTE: *For convenience sake, the throttle grip adjusting screw can be used to keep the engine turning at 4000 rpm. Hold the throttle open until the tach reads correctly, then turn in the adjusting screw.*

4. Turn off the engine and disconnect the tester leads from the battery, then set the tester to the 12 amp DC range, and switch the tester leads to the appropriate meter sockets.

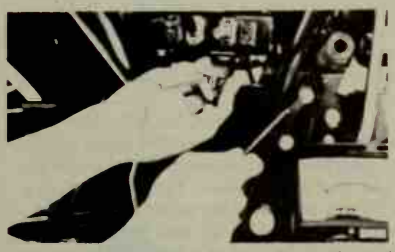
5. Disconnect the wire which runs from the fuse to the starter relay, and connect the positive (+) tester lead to the white wire on the fuse side, and the negative (−) tester lead to the white wire on the relay side. This puts the tester in series with the rectifier and battery so that battery charging current can be measured.

CAUTION: *Do not use the electric starter if the tester is connected in series directly at the battery terminal instead of as directed in*

Dynamo test connections

the preceding Step, or the reverse starting current will damage the meter.

6. Start the engine and run it at 4000 rpm, taking note of the meter reading. A reading of 9.5 amps or more is normal, and a lower reading indicates a defective dynamo.



7. Determine whether the problem is in the windings or the rotor in the following manner:

a. Disconnect the blue plug from the connector panel, and use the R x 1 scale on the tester to determine the resistance between each pair of wires going to the plug: blue/pink, blue/yellow, and pink/yellow.

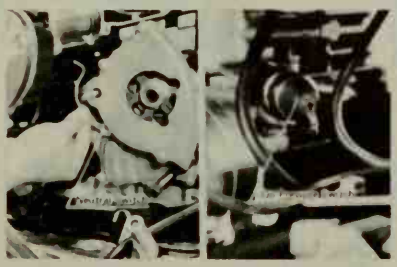
b. The resistance between any two of the wires should be 0.45–0.6 ohms; less indicates shorted coils, and a higher resistance or none at all indicates open coils. If the coils are defective, the stator must be replaced.

c. Measure the resistance between each dynamo wire and ground (the chassis,

Testing the connector panel plug

Measuring resistance between the leads and ground

engine, etc.) using the highest resistance scale on the tester.



d. No reading (∞) is normal, and any reading indicates a short which means the stator must be replaced.

e. If the coils have normal resistance, but voltage and current checks indicate that the dynamo is defective, the rotor magnets are probably bad, and the rotor will have to be replaced.

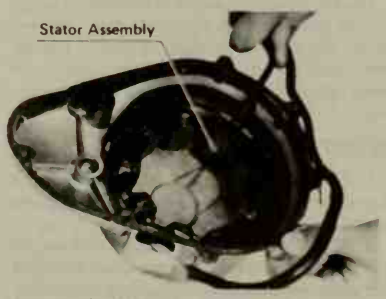
REMOVAL AND INSTALLATION

1. Remove the chain cover as described in the "Engine Removal and Installation" Section.

2. Remove the right-side plastic cover, and disconnect the blue dynamo wire, and the wires from the oil pressure and Neutral indicator switches, then release the wires from the cable clamps.

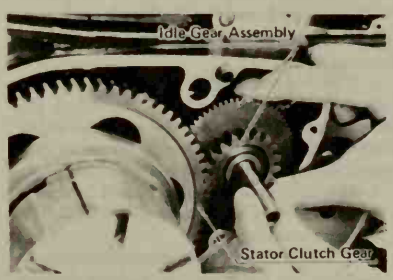
Disconnecting the switches

3. Remove the left-side engine cover, and remove the allen bolts which secure the stator to the cover.



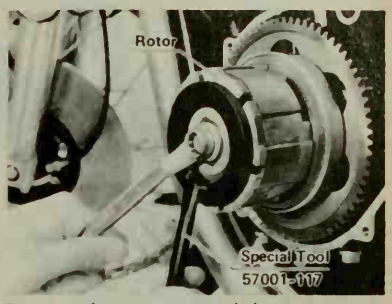
NOTE: *If only the rotor is to be removed, it is not necessary to disconnect the wiring or remove the stator.*

4. Remove the starter idle gear.

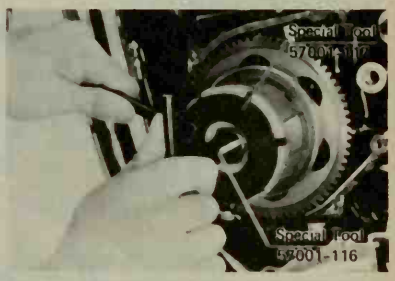


5. Keep the rotor from turning by holding it with either the special tool (Part No. 57001-117) or a suitable substitute, and remove the rotor mounting bolt.

6. Hold the rotor still as described above, and use either the special tool (Part No. 57001-116) or a suitable substitute to remove the rotor-starter clutch assembly.

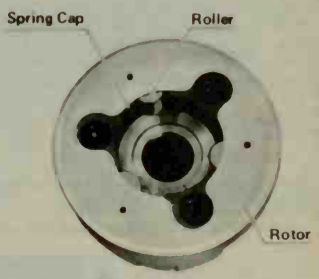


CAUTION: *Hammering on the rotor will*

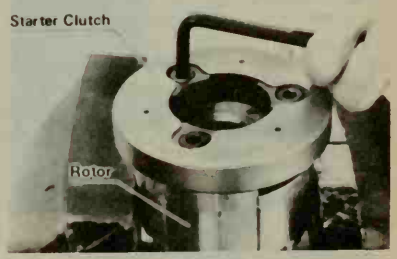


Removing the stator

Removing the idle gear assembly



Removing the rotor mounting bolt

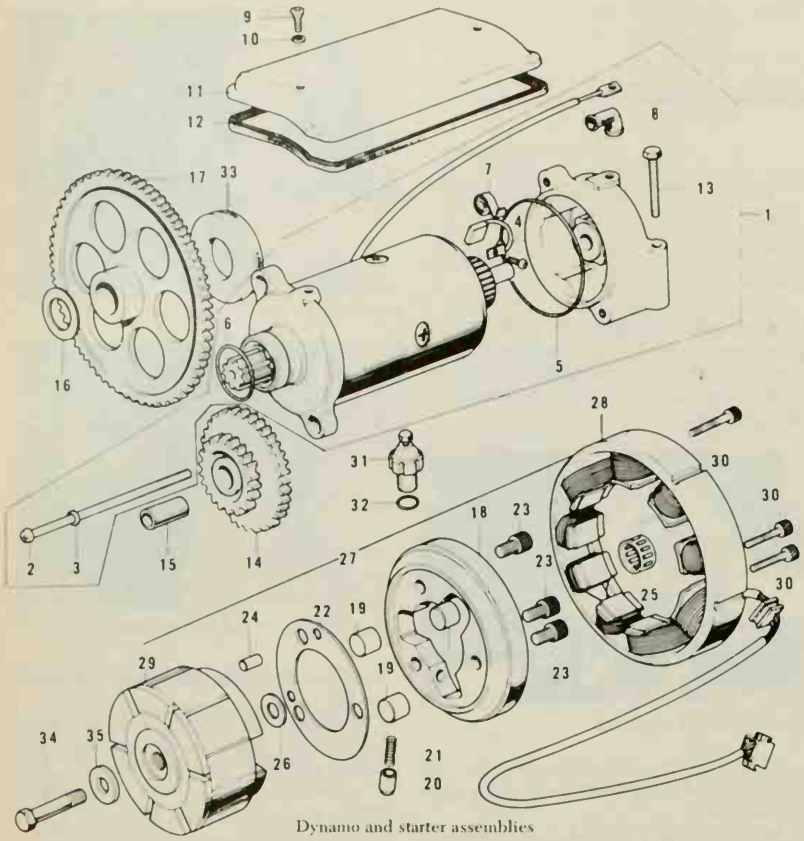


Removing the rotor and starter clutch assembly

demagnetize the magnets, leaving the rotor useless.

7. Remove the woodruff key, thin shim, starter clutch gear, needle bearing, gear damper, and thick shim, in that order, from the crankshaft, then remove the rollers, springs, and spring caps from the starter clutch.

Starter clutch assembly



Disassembling the starter clutch

8. Secure the rotor in a wood-jawed vise, or wrap it to protect it if a metal vise is to be used, and remove the allen bolts to separate the rotor and starter clutch.

9. Installation is in the reverse order of removal. Use a new cover gasket, apply Loctite or some other suitable sealer to the allen bolts, and be sure to use an oil seal guide when installing the chain cover.

10. Place the thick shim onto the crankshaft

with its chamfered side facing in before installing the starter clutch.

11. Spin the clutch gear so that the rollers

Install the shim with the chamfered side in

will move enough to allow it to go on when installing the starter clutch.

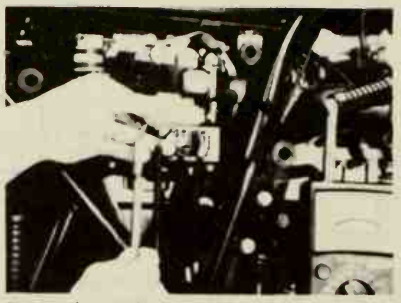
12. Apply Loctite, or another suitable sealer, to the rotor mounting bolt threads before installing it, and torque the bolt to 18 ft lbs (2.5 kg/m).

Rectifier

A six-diode (two for each of the alternator's 3 output phases) rectifier is used to convert the AC current produced by the dynamo into the DC current needed to run the battery charging, ignition, lighting, and horn circuits.

Diodes can only conduct current from negative to positive, and therefore they convert AC to DC. If the rectifier, or any of the diodes, goes bad it will conduct in both directions, or not at all, leading to a discharged battery.

RESISTANCE TEST



1. Disconnect the white rectifier plug from the connector panel, and the white lead going to the battery.

2. With the tester set on the R x 10, or the R x 100 range, check the resistance between the white rectifier lead and each of the yellow leads, the yellow leads and the white lead, the black lead and each yellow lead, and each yellow and black lead. This means a total of 12 measurements.

3. The resistance should be low in one direction, and about ten times as great in the other. If the readings are high or low in either direction for any pair of wires, the rectifier is defective and must be replaced.

NOTE: *The lower reading should be within ⅓ scale of zero ohms regardless of the type of tester used.*

CAUTION: *When removing or installing a rectifier, do not loosen or tighten the nut which holds the rectifier assembly together as this will damage the unit.*

Testing the rectifier

Regulator

The regulator is a sealed solid state unit which must be replaced if defective. It functions to limit voltage to a maximum of about 15–16 volts, and is so constructed to act over each of the 3 phases of dynamo output.

Two symptoms which would indicate the possibility of a faulty regulator are repeated battery discharging or overcharging. Overcharging is indicated by the need to top up the electrolyte level more frequently than normal, and by light failures when running at high rpms. Discharging is indicated by a battery which checks out okay, but goes dead quickly after being charged.

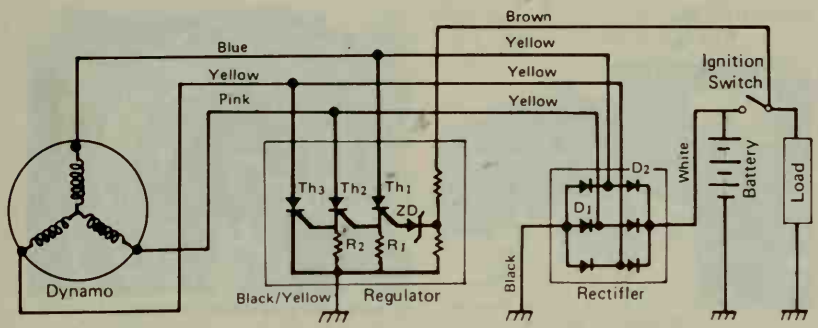
OPERATIONAL TEST

In Circuit

NOTE: *Make sure that the battery is in good condition, and is well charged before beginning the test.*

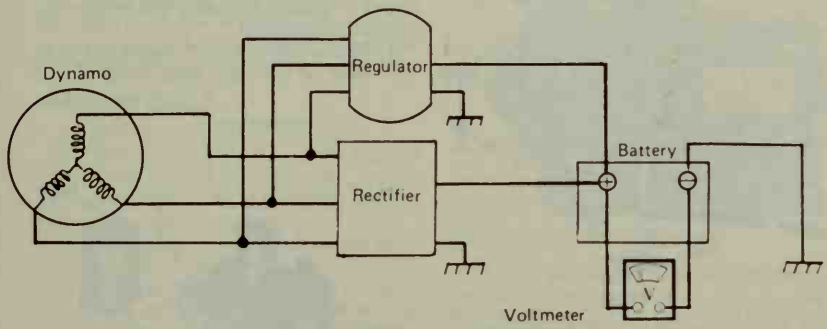
1. Set the tester to the 30 VDC range, and connect it across the battery (tester negative lead to battery negative terminal, and tester positive lead to battery positive terminal).

2. Run the engine, with all lights and accessories turned off, at 4000 rpm while checking the meter. If the meter reads between 15–16 volts, the regulator is functioning normally; if it reads over 16 volts the regulator is either improperly connected or defective; and if the reading is less than 15 volts either the dynamo, rectifier, or regulator needs to be replaced. Go on to the next Step if the reading was low.



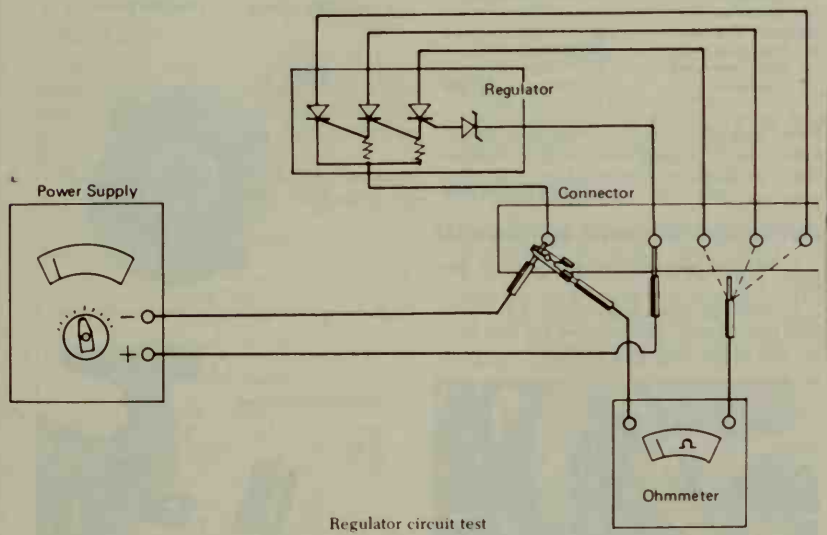
3. Turn off the engine, but leave the tester connected as is. Disconnect the green regulator plug from the connection panel under the right-side plastic cover. Run the engine at 4000 rpm and check the meter reading. If the reading is within 15–20 volts the regulator is defective; if the reading is less, then either the dynamo or rectifier is defective.

4. Before replacing the regulator, make sure that all the connections are clean and snug, as poor connections could cause misleading test results.

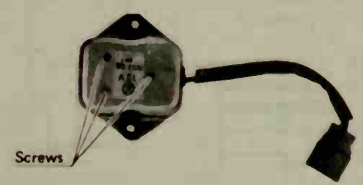


Out of Circuit

CAUTION: *When removing the regulator do not loosen or remove the screws in the regulator body. The screws aid in heat dissipation, and the unit will overheat if they are not properly installed.*



1. Set the meter on the R x 10 or R x 100 scale. There should be 1,000–1,100, ohms resistance between the black and brown leads, and no reading (∞) between any other two



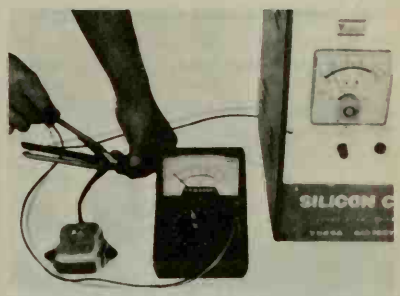
Rectifier and regulator circuit

Testing with the regulator in circuit

Regulator circuit test

Do not remove these screws

leads, or between the black or brown and any other lead. Any other results indicate that the regulator is defective.



2. For this test a 14 VDC and a 16–17 VDC power source must be available. If the sources used cannot provide sufficient power, the tests will be inaccurate, and if more than 18 volts are passed through the regulator it may be damaged. Proceed as follows:

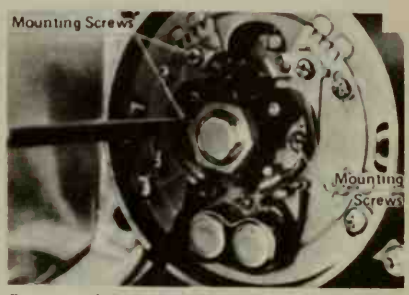
CAUTION: *If the voltage source and regulator are connected backwards for even a moment, the regulator will be damaged.*

a. Connect the regulator to the 14 VDC source as shown in the accompanying illustration.

b. Set the meter to either the R x 10 or the R x 100 range, and check that there is no reading (∞) between the black lead and the pink, yellow, or blue lead. If the meter gives any reading for any wire, the regulator is defective.

CAUTION: *When performing the next test, be sure that the black and brown leads never touch the meter leads at the same time or the meter will be damaged.*

Testing the regulator out of circuit



c. Connect the regulator to the 16–17 VDC source in the same manner as in Step "a", and set the meter on the R x 1 scale. This should result in a very low reading when the meter is connected one at a time between the black lead and the blue, pink, or yellow leads. If there is no reading between any or all of the leads, or if any one reading is higher than the other two, the regulator is defective and must be replaced.

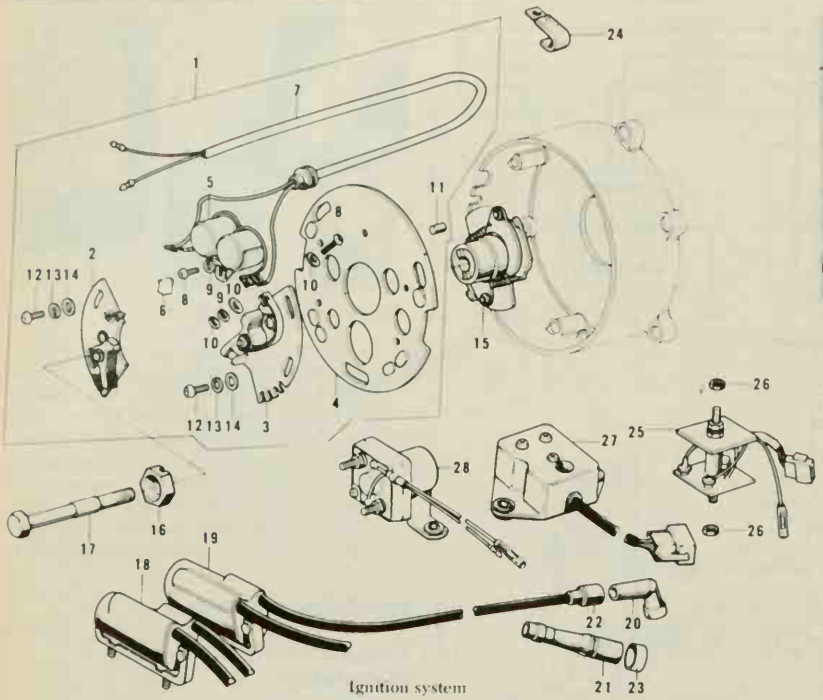
IGNITION SYSTEM

Component Removal and Installation

CONTACT BREAKER POINTS

1. Remove the breaker point cover and cover gasket, then remove the two mounting screws for each set of points, and remove the points.

Removing the point mounting screws



NOTE: *You may remove the mounting plate with the points and condensers in place, and then install a new plate with the points and condenser already mounted on it. Consult the "Automatic Advance Mechanism" Section for further information.*

2. Loosen the nut at the leaf spring, and disconnect the condensers if they are to be reused. It is best to replace the points and condensers at the same time.

Disconnecting the condensers from the points

3. When installing the points make sure that the wire connectors are positioned on the

26. Nut
27. Voltage regulator
28. Magnetic switch assy

outer part of the insulating washer. Do not overtighten the nuts as this may damage the washers causing electrical leakage.

CONDENSERS

1. The condensers are secured to the mounting plate by a single mounting screw. If they are being removed in conjunction with the points, follow Step 1 in the previous section, then remove the condensers mounting screw and disconnect the lead wires.

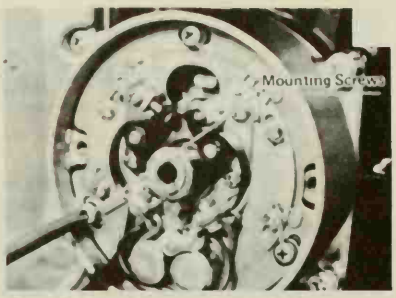
Removing the condensers

2. If the condensers alone are to be removed, remove the mounting screw and loosen the nuts at the lead spring to free the wires. Consult Step 3 in the previous Section.

Testing Condensers

Condensers are generally not tested for poor operation since they are so inexpensive to replace. Arcing across the points when they are open, badly pitted or burned points, or damaged leads indicate the need for condenser replacement.

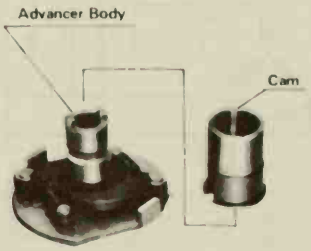
The condensers can be tested by replacing them and checking for improved performance, or by testing them with a capacitor tester as illustrated. The condenser specifications are 0.25± 0.03 mfd., 1000 VDC.



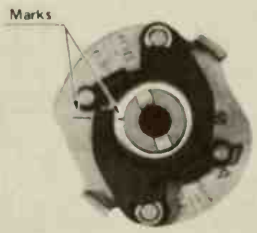
AUTOMATIC ADVANCE MECHANISM

1. Remove the points cover and cover gasket.

2. Hold the crankshaft rotation nut steady with one wrench, then remove the bolt from the end of the shaft with another.

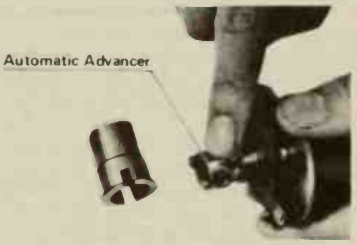


Removing the shaft nut

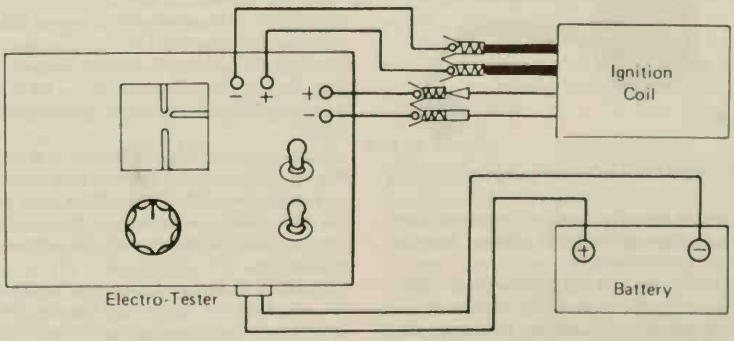


Removing the plate mounting screws

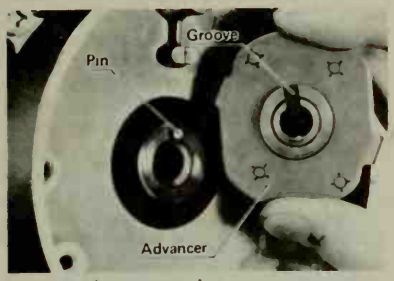
3. Remove the 3 mounting plate mounting screws to remove the plate, and remove the advance mechanism.



4. Disassemble the unit, replace any damaged parts (or the whole unit), assemble it so



The cam slips right off the advancer body



Line up these marks when assembling the unit

Greasing the shaft

Condenser test circuit

Lining up the groove and pin

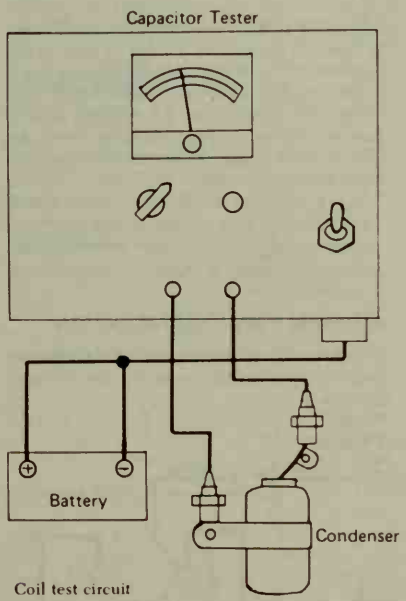
that the marks line up, and grease the shaft before installing the breaker cam.

5. When installing the mechanism be sure that the pin on the crankshaft fits into the groove in the back of the advancer, and that the crankshaft rotation nut is properly seated.

IGNITION COILS

1. Remove the fuel tank.

2. Disconnect the black or green wire (as the case may be), and the brown wire, remove the spark plug leads from the plugs, and unbolt and remove the coil(s).



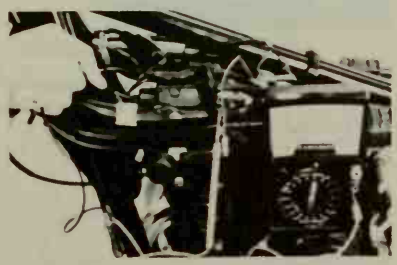
NOTE: *The high tension leads cannot be removed from the coil.*

3. When installing coils match the color coded black and green wires. The brown wire goes with the yellow-red lead from the battery. Each plug lead is numbered for the appropriate cylinder.

Testing Coils

Coils can be stested by replacing them and seeing if performance is enhanced, by testing them with an electro-tester, or by checking for a shorted or open condition using an ohmmeter.

Hook up the coil to the electro-tester as indicated in the accompanying illustration. Replace the coil if it won't produce a spark at least 7 mm (0.28 in.) long.



Coil test circuit

Test the coil using an ohmmeter in the following manner:

1. Check the primary winding resistance between the red/yellow lead and the green or black lead. If the results are not between 3.2–3.8 Ω the coil must be replaced.

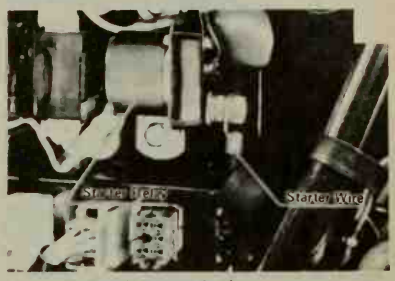
Testing the primary windings

Testing the secondary windings

2. Check the secondary winding resistance between the two spark plug high tension wires. If the result is not about 30K Ω the coil must be replaced.

3. Set the ohmmeter on its highest scale and check the resistance between the brown wire and the plug wires or the coil core. If the reading is not infinity (∞), the coil must be replaced.

NOTE: *The test with an ohmmeter is not 100% accurate as it doesn't test for high voltage shorts (insulation breakdown).*



Starting System

CAUTION: *Do not keep the starter button depressed if the starter motor doesn't respond as this may burn out the starter windings. Do not continue to operate the starter for more than 30 seconds if the engine doesn't start, and let it cool off for about 2 minutes if you do operate it for long.*

REMOVAL AND DISASSEMBLY

1. Remove the fuel tank, carburetors, starter cover and cover gasket, and the chain cover.

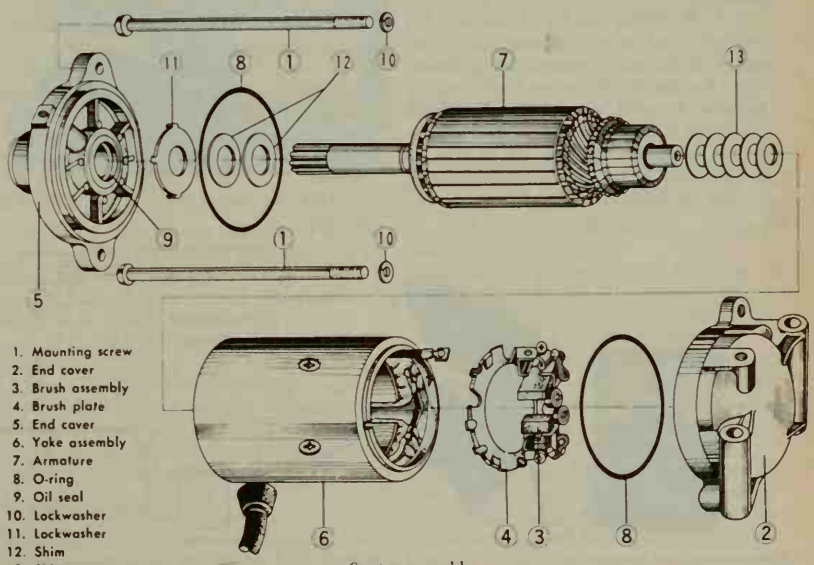
2. Remove the right-side plastic cover, unscrew the starter wire from the starter relay terminal, and free the wire from the cable clamp.

Disconnecting the starter leads

3. Remove the two starter mounting bolts, and remove the starter.

4. Remove the two mounting screws (1), and remove the end cover (2).

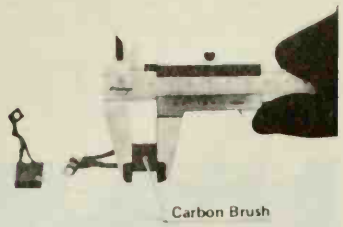
5. Disconnect the brush assembly (3) from the field coil lead, then remove the brush plates (4) and remove the brushes.



6. Remove the remaining end cover (5), and remove the yoke assembly (6) and armature (7).

7. Remove the starter clutch as described in the "Dynamo Removal and Installation" Section.

INSPECTION



1. Inspect the carbon brushes for excessive wear or damage, and replace them if worn past the standard of ½ in. (13–13 mm) by ¼ in. (7 mm) or more. Always replace the brushes as a pair.

2. Inspect the brush springs for a worn, damaged, or collapsed condition and replace them as necessary. The spring tension should be 20–24 oz (560–680 g) as measured with a spring gauge, but the spring may be considered serviceable if it will snap the brush firmly into place.

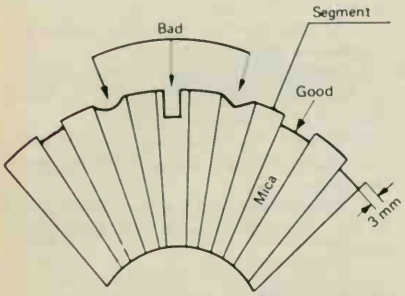
13. Shim

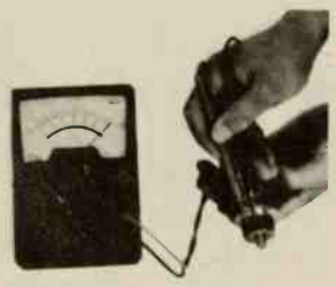


Starter assembly

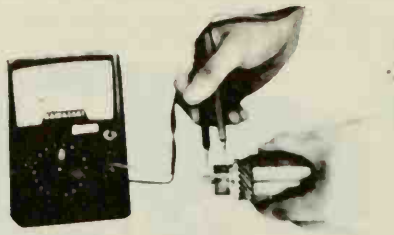
Measuring a carbon brush

3. Inspect the commutator for a worn, scored, or otherwise damaged condition, and turn it down or clean it up with fine emery paper if necessary. If brush dust is caught in the commutator grooves it must be cleaned out thoroughly, and the mica should be cut square as illustrated.

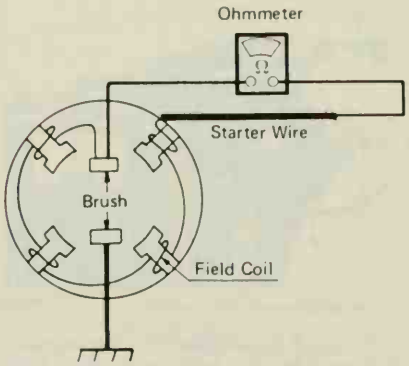
4. Test the commutator in the following manner:



The commutator grooves should look like the "good" one



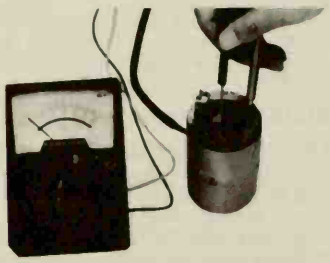
a. Turn the meter switch to the R x 1 scale, and measure the resistance between each two segments of the commutator. High resistance or no reading at all between any two, indicates that wire is open and the armature must be replaced.



b. Turn the meter switch to the highest scale, and measure the resistance between the commutator and the shaft. Any reading at all indicates that the armature is grounded.

c. If the above checks do not reveal a problem, and after checking the other starter circuit components no fault is discovered, the nature of the problem may be such that it cannot be isolated with a meter. Therefore if after thoroughly checking the system the starter still fails to turn over, or only operates feebly, replace the armature.

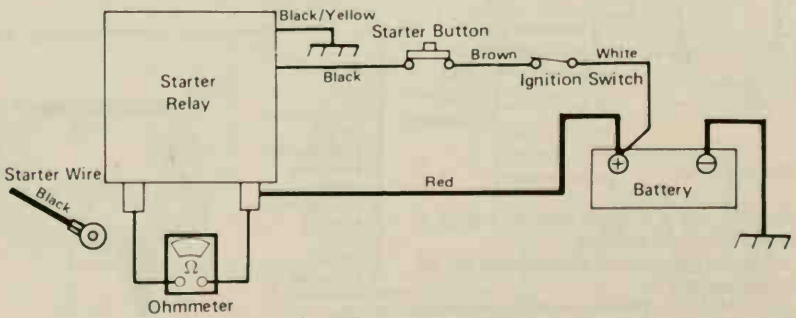
5. Test the field coils in the following manner:



Testing resistance between segments

Testing resistance between the commutator and shaft

Field coil test circuit



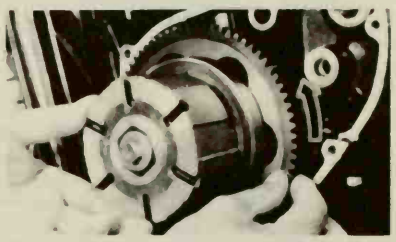
a. Turn the meter switch to the R x 1 scale, and measure the resistance between the carbon brush on the positive side, and the starter lead. If the reading is not close to zero ohms, or if there is no reading, the

Testing the resistance between the positive brush and the yoke

field coils are open and the yoke assembly must be replaced.

b. Turn the meter switch to the highest scale, and measure the resistance between the positive side brush and the yoke (housing). Any reading indicates that the coils are shorted to ground, and the yoke must be replaced.

6. Test the starter relay in the following manner:



Starter relay contact test circuit

a. Disconnect the starter wires from the relay, and connect a meter set on the R x 1 scale, across the relay terminals.

b. Press the starter button and see if the meter reads zero ohms. If the relay clicks once and the meter reads zero, the relay is good. If it clicks, but the meter does not read zero, the relay is defective and must be replaced. If the relay doesn't click at all, disconnect the black and yellow/black wires and measure the resistance across them. If the reading is not close to zero, the relay is defective.

c. If the reading is zero, the relay may be good, but there may be no current getting to it. Turn the tester switch to the 30 VDC scale and connect the negative (−) meter lead to the yellow/black relay lead, and the positive (+) tester lead to the black wire. When the starter button is pushed, the meter should read battery voltage. If it doesn't the problem is in the wiring. If the meter reads battery voltage, but the relay doesn't click, the relay is defective.

7. If the starter works, but doesn't disengage after the engine starts, the starter clutch rollers or gear may be damaged or worn. Such damage could also prevent the starter from engaging properly, or could cause noisy operation while the engine is running.

The clutch should not be able to rotate in the direction of the arrow

Test the clutch by rotating the clutch gear by hand. It should not be able to turn in the direction of the arrow, but should turn freely in the opposite direction. If the clutch does not operate correctly, or if it operates noisily, disassemble and inspect all components for wear or damage, and replace those whose condition is even marginal.

NOTE: *Damage to either the starter clutch gear, the idle gear, or the starter gear may cause damage to the other gears. Inspect them all carefully if any are damaged or excessively worn.*

ASSEMBLY AND INSTALLATION

1. Assembly is in the reverse order of disassembly, and installation is in the reverse order of removal.

2. Carefully clean off any dust from the shaft as this may result in premature wear, and dampen the shaft felts with fresh oil.

3. Take care not to damage the O-rings and oil seals when installing the end covers, and align the marks on the covers and housing.

Make sure that the marks are aligned on both ends

4. Lubricate the O-ring with a small amount of fresh oil before slipping the starter into place.

5. Apply Loctite, or another suitable sealer, to the starter mounting bolts before installing them.

ELECTRICAL EQUIPMENT

Switches

The switches are not repairable, and must be replaced if defective. The switches can be disassembled and cleaned, but no replacement parts are available.

Use a meter to determine whether the connections given in the following charts are good. The meter should read zero ohms for any of these connections.

Intermittent loss of spark to either pair of cylinders may be caused by a shorted kill switch. The best way to test for this is to remove the switch from the circuit, and see whether or not you continue to drop cylinders.

Turn Signals

The turn signals are a complete circuit, and a loose connection, bad wiring, or a burned out bulb will incapacitate the entire system. Usually, if the trouble is common to both the left and right turn signals, the problem is in the relay, although it may be in the switch, wiring, or due to a poorly charged battery. If the problem is isolated in either the right or left sides, the problem is not in the relay, but may be in the switch, wiring, or bulbs.

Testing the turn signal relay

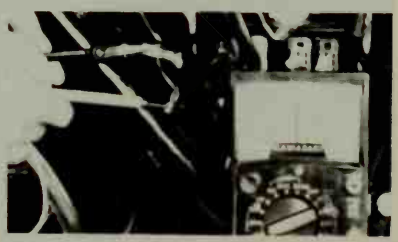
Troubleshoot the system in the following manner:

1. If neither the right or left signals come on, check the following:

a. Check the state of battery charge.

b. Disconnect the relay and use a meter to check for continuity through the relay terminals. If the reading is not close to zero ohms (i.e., no reading or one of several ohms), replace the relay.

c. If the relay is good, turn the meter switch to the 30 VDC scale, and connect the positive (+) meter lead to the brown wire which goes to the relay, and the negative (−) tester lead to the orange wire. Turn on the ignition, and flip the turn signal switch from right to left. If the meter registers battery voltage but the lamps don't work, recheck the wiring and bulbs. If the meter doesn't register battery voltage, either the switch or wiring is bad.



2. If both the right or left signals come on and stay on, or blink too slowly, check the following:

a. Check the state of battery charge.

b. Check all of the wiring connections.

c. Check that the bulbs, both the flasher and the indicator, are of the correct wattage.

d. Replace the relay if the above Steps check out.

Testing the relay leads

3. If one lamp on one side comes on, but the other doesn't, check the lamp that's out for a bad bulb or bad wiring.

4. If neither lamp on one side comes on, check both bulbs and the switch.

5. If the flashing rate is too fast, check the following:

a. Check for an overcharged battery if this occurs on both sides. If the battery and dynamo check out, replace the relay.

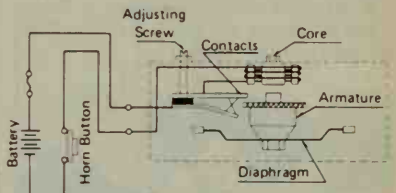
b. If this only occurs on one side, check that the wattage of the bulbs is correct.

Instruments

Both instruments are sealed units which cannot be repaired except for bulb replacement. Replace the bulbs by disconnecting the instrument from its cable and mount (it is not necessary to disconnect the wiring in the headlight shell), and pull out the plug connector for the offending bulb. Make sure that you replace the bulb with one of the correct wattage.

Oil Pressure Switch

SWITCH TESTING



The switch should turn on the indicator light when the key is on but the engine is not running. If the light doesn't come on, disconnect the lead from the switch and use an ohmmeter to check for continuity between the switch body and the switch terminal. A dead short indicates that the problem is either in the wiring or bulb. If the reading is not zero ohms, the switch is defective and must be replaced.

If the lamp stays on and you've already followed the instructions in the preceding Section, disconnect the lead from the switch, and connect an ohmmeter between the switch terminal and ground. With the engine off the meter should read zero ohms, and with the engine running the meter should indicate an open (∞) condition. If the meter still indicates a short when the engine is running, shut it down and run a pressure test as directed in the "Lubrication System" section. The switch is probably defective.

NOTE: *Always coat the switch threads with Loctite, or another suitable sealer, when installing it.*

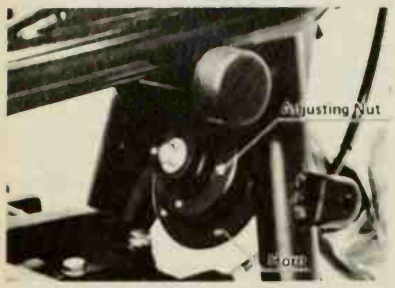
Horn

Most horn troubles, unless caused by maladjustment, can be traced to the contacts. The contacts wear and must be periodically adjusted. If adjusting the contacts doesn't correct the problem, the contacts are probably dirty or pitted.

Horn diagram

ADJUSTMENT

1. Remove the fuel tank, then disconnect the black horn wire, and connect a meter into the circuit so that the positive (+) tester lead goes to the black wire on the horn side, and the negative (−) tester lead goes to the remaining black wire.



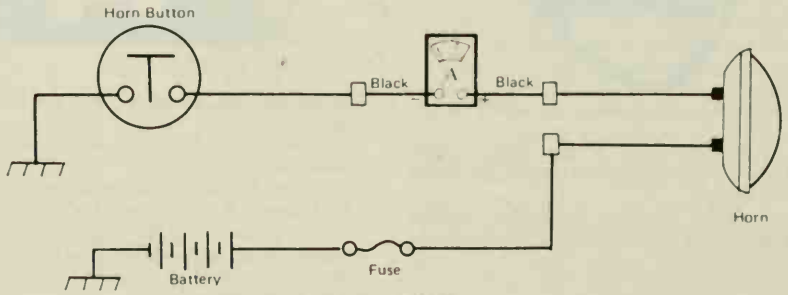
2. Turn on the ignition, and depress the horn button while turning in the adjusting nut until the horn sounds its best. Keep the horn current between 1.8 and 2.5 amps.

CAUTION: *Do not turn the adjusting nut in too far as this may damage the spring inside the horn, and increase the horn current to a point where the horn coil may be burned out.*

3. If the horn doesn't sound right, first make sure that no cables or other components are touching it, and if this doesn't help, clean the contacts as described in the following Section.

Testing the horn

Horn adjusting nut location



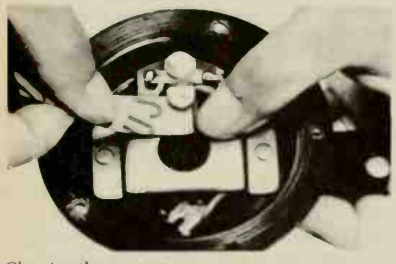
5. Inspect the horn assembly for signs of water damage, and replace the gasket with a homemade one if it appears to be water damaged.

ELECTRICAL TROUBLESHOOTING

If you've got an electrical problem that you can't trace, especially if it is an intermittent one, chances are that it's due to poor contact of the male and female connectors in the electrical panel. This may be due to the failure of one of the connectors to seat properly in the plastic plug jack, so when the panel is plugged together one of the pins or receptors backs out causing a poor contact. Vibration can also figure in this, causing a poor connection while the machine is running, but checking out okay when sitting dormant.

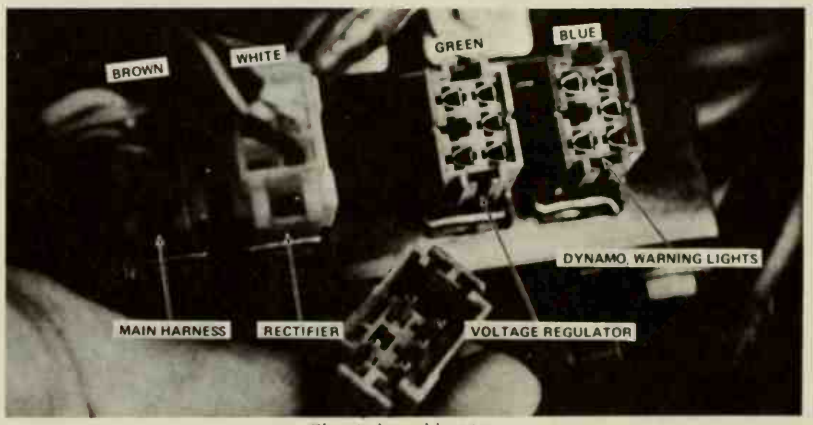
Alleviate this sort of problem by tugging at each wire until a loose one is discovered, then push it back in until you feel the small locking tang reach its seat. Pull on the offending wire a few times again to make sure that it's now properly seated.

The following table will help you locate a connector-based problem more easily:



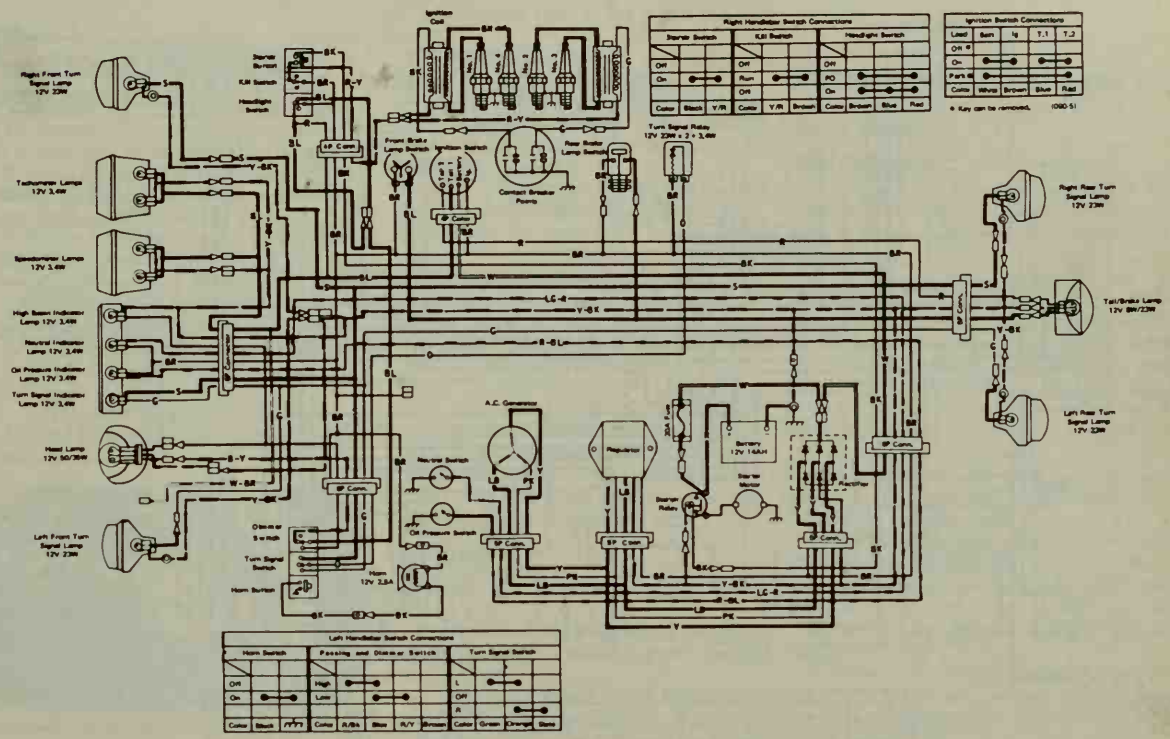
Horn test circuit

REPAIR



CAUTION: *Do not loosen the core or armature mounting as this will necessitate fine adjustments not given here.*

1. Check horn continuity with a meter connected to the black and brown leads. If the reading is close to zero ohms, the horn should be adjusted.
2. If the reading is several ohms, if there is no reading, or if adjustment will not correct the problem, remove the screws around the perimeter of the horn to disassemble it.
3. Clean the contacts with fine sandpaper or emery cloth until you get a reading of zero ohms resistance across the contacts.
4. If there is still high resistance, or if there is still no reading, the coil is burned out and the horn must be replaced.



Cleaning the contacts

Blue Plug:	The blue plug contains 3 leads from the dynamo, one lead from the Neutral light, and one from the oil pressure warning light. A poor connection here could mean the battery would not charge, leading to a dead battery, or failure of one of the warning lights to illuminate.
Green Plug:	The green plug goes to the voltage regulator. A poor connection here could overcharge the battery, possibly causing it to boil over. Usually, the first indication of a problem is burning out of the headlamp or other lamps.
White Plug:	The white plug leads to the rectifier. A bad connection here could fail to charge the battery, leading to a dead battery.
Brown Plug:	The brown plug supplies the main electrical harness, including the starter, the lights, the horn, and the ignition. Poor connection could mean no lights, no horn, no electric start, or no ignition.

Z1A/B

WIRING DIAGRAMS

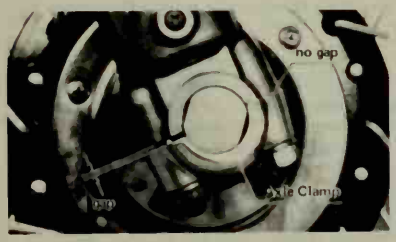
KZ900

KZ1000

CHASSIS

WHEELS

Removal and Installation



FRONT WHEEL

1. Disconnect the speedometer cable at the front wheel, using pliers if necessary.
2. Block up the motorcycle so that the front wheel is off the ground, or use a jack placed under the engine to raise the bike.
3. Remove the nuts which secure the axle clamps, then remove the clamps. The front wheel is now free to be removed.

CAUTION: *Do not operate the front brake while the front wheel is removed or the caliper piston will be forced out of the cylinder.*

4. Installation is in the reverse order of removal. Note the following:

a. The axle clamp has a front and rear end, and must be installed so that the gap at the rear is even.

Axle clamp correctly installed

b. Secure the front clamp nut first, and then the rear, to a specified torque of 13–14.5 ft lbs (1.8–2.0 kg/m). Check for an even gap at the rear.

c. Rotate the front wheel while installing the speedometer cable until the speedometer drive shaft will seat in the grooved end of the cable, then secure the cable.

REAR WHEEL

Drum Brake

1. Place the motorcycle on its center stand, or block up the rear wheel of the machine so that it isn't resting on the ground.
2. Remove the axle nut cotter pin, and loosen the axle nut.
3. Remove the brake torque link cotter pin, nut, and washer at the brake hub, then disconnect the torque link.
4. Remove the brake adjuster nut from the brake rod.
5. Remove the bolts which secure the chain adjuster stoppers, pull back on the rear wheel to take up any slack in the chain, rotate the adjusters down out of the way, and remove the stoppers.
6. Push the rear wheel forward until the chain can be slipped off the sprocket to the left, then pull the wheel back and off the frame. It may be necessary to shift the top of the wheel to the right to get it past the rear fender.
7. Installation is basically in the reverse order of removal. Note the following:

a. Start the chain onto the sprocket before slipping the wheel assembly onto the frame or it will get stuck on the nuts which secure the sprocket.

NOTE: *If this operation proves too difficult, loosen the left-side muffler mounting, and remove the chain guard to gain greater access.*

b. Adjust the chain, as described in the "Maintenance" section, before securing the axle and torque link nuts.

c. Secure the torque link nut to 22–25 ft lbs (3–3.5 kg/m) and install a new cotter pin.

d. Center the brakes by spinning the rear wheel and sharply applying the brake, then secure the axle nut without releasing the brake. Secure the axle nut to 95–115 ft lbs (13–16 kg/m), and install a new cotter pin. Adjust the brakes.

Chain adjuster stopper location

Disc Brake

1. Park the motorcycle on the center stand.
2. Disconnect the brake line at the caliper and hang it in such a way as to prevent excessive fluid loss.
3. Unbolt the torque link at the caliper.
4. Remove the chain guard.
5. Loosen the axle nut. Disengage the caliper from the torque link.
6. Back off both chain adjuster bolts and bend the adjusters down and out of the way. Push the wheel forward as much as possible.
7. Remove the bolts and take out the chain adjuster stoppers.
8. Disconnect the chain from the rear sprocket.
9. Pull off the wheel and caliper together.
10. To remove the caliper, remove the axle nut and pull out the axle.
11. Installation is the reverse of removal. Note the following points:

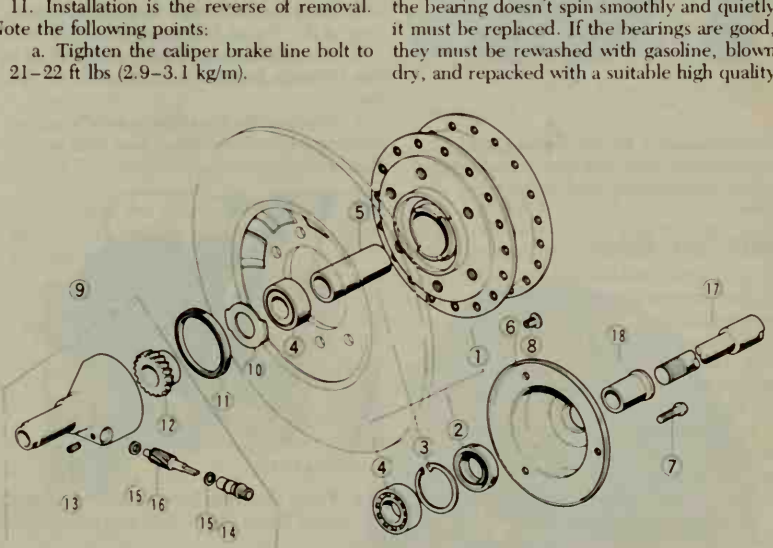
a. Tighten the caliper brake line bolt to 21–22 ft lbs (2.9–3.1 kg/m).

b. After installing the wheel, bleed the brake as outlined in the brake section following.

WHEEL HUBS AND BRAKES

Front Hub

DISASSEMBLY



1. Remove the wheel as described in the "Wheels Removal and Installation" Section. Refer to the accompanying illustration and the "Caution."
2. Hold the gearbox (9) stationary, and unscrew the axle (17). The speedometer pinion (16) and bushing (14) are secured by the bushing set pin (13), and may be removed if necessary. The speedometer gears (12 and 10), and the oil seal (11) may be removed at this time.

CAUTION: *If the axle is held stationary and the gearbox is rotated, the speedometer drive gear will be damaged.*

3. Remove the collar (18), caps (8), and wheel cap (6). If you wish to remove the disc, remove the six bolts which secure it.
4. Use a suitable drift to knock the left-side bearing (4) free from its seat. Approach it from the right, and apply pressure only to the inner race.
5. Remove the distance collar (5) and oil seal (2).
6. Remove the retaining ring (3) from the left-side of the wheel, and tap evenly around the inner race of the right-side bearing until it comes out.
7. Consult the "Front Disc Brake" Section for additional information on the front disc brake master cylinder and caliper assemblies.

INSPECTION

1. Clean all parts, except the bearings and seals, thoroughly in a suitable solution, then blow them dry.
2. Clean the bearings with gasoline and blow them dry. Lubricate them with clean oil, then spin them to check for wear or damage. If the bearing doesn't spin smoothly and quietly it must be replaced. If the bearings are good, they must be rewashed with gasoline, blown dry, and repacked with a suitable high quality

16. Speedometer pinion
17. Axle
18. Collar

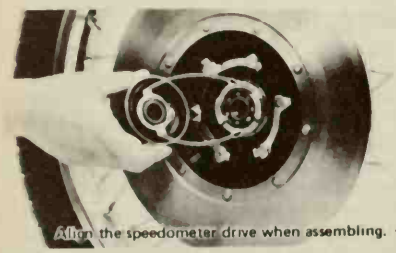
bearing grease. Spin the bearing a few times to circulate the grease evenly.

CAUTION: *Never spin dry bearings under any circumstances.*

3. Check all parts for a worn or damaged condition, and replace them as necessary. Oil seals must be replaced if even only slightly damaged or cracked, and should be replaced as a matter of course.

4. Consult the "Front Disc Brake—Disc" Section for additional information concerning the disc.

ASSEMBLY



1. Assembly is basically in the reverse order of disassembly.

2. Replace the oil seals with new ones, and install the bearings using either the special bearing driver holder and bearing driver (Part No. 57001-139 and 57001-140) or a suitable substitute.

3. Align the speedometer drive, as illustrated, during installation.

Installing a wheel bearing

Installing the speedometer drive

4. Remember to hold the gearbox stationary and screw in the axle to avoid damaging the speedometer gear drive.

Front Disc Brake

CAUTION: *Read and observe the following before beginning any work on the disc brake assemblies:*

1. Never re-use old brake fluid.

2. Do not use fluid from a container that has been left unsealed, or that has been open a long time.

3. Do not mix two types of fluid for use in the brakes. This lowers the brake fluid boiling point and could cause the brake to be ineffective. It may also cause the rubber brake parts to deteriorate. Recommended fluids are shown below.

NOTE: *The type of fluid originally used in the disc brake is not available in most areas, but it should be necessary to add very little fluid before the first brake fluid change. After changing the fluid, use only that one type thereafter.*

Brake lever	45 ~ 60 in. lbs	0.5 ~ 0.7 kg/m
Brake lever adjuster	70 ~ 100 in. lbs	0.9 ~ 1.2 kg/m
Master cylinder clamp	55 ~ 75 in. lbs	0.63 ~ 0.88 kg/m
Fitting (banjo) bolts	19 ~ 23 ft lbs	2.5 ~ 3.3 kg/m
Brake pipe nipple	150 ~ 155 in. lbs	1.7 ~ 1.8 kg/m
3-way fitting mounting	45 ~ 50 in. lbs	0.5 ~ 0.6 kg/m
Pressure switch	135 ~ 170 in. lbs	1.5 ~ 2.0 kg/m
Caliper shafts	22 ~ 26 ft lbs	3.0 ~ 3.6 kg/m
Caliper mounting	19 ~ 23 ft lbs	2.5 ~ 3.3 kg/m
Bleeder valve	70 ~ 85 in. lbs	0.8 ~ 1.0 kg/m
Disc mounting bolts	140 ~ 190 in. lbs	1.6 ~ 2.2 kg/m

Atlas Extra Heavy Duty
Shell Super Heavy Duty
Texaco Super Heavy Duty
Wagner Lockheed Heavy Duty
Girling Amber

The correct fluid will come in a can labeled SAE J-1703 or D.O.T.3. Do not use fluid that does not have one of these markings.

4. Don't leave the reservoir cap off for any length of time as moisture may be absorbed into the fluid.

5. Don't change the fluid in the rain, or when a strong wind is blowing.

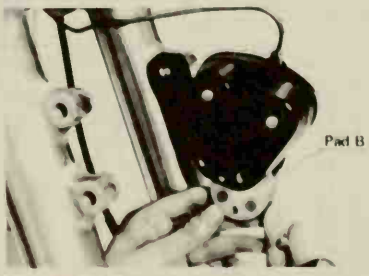
6. Use only disc brake fluid, isopropyl alcohol or ethyl alcohol for cleaning brake parts, but do not allow rubber parts to remain in contact with the alcohol for more than 30 seconds.

7. Brake fluid will damage painted surfaces; any spilled fluid should be wiped off immediately.

8. Do not use gasoline, motor oil, or any other mineral oils near disc brake parts; these oils cause deterioration of rubber brake parts. If oil spills on any brake parts it is very difficult to wash off and will eventually reach and break down the rubber.

9. If any of the brake line fittings or the bleeder valve is loosened at any time the air must be bled from the brake.

10. Prescribed torque values for tightening disc brake parts mountings are as above.



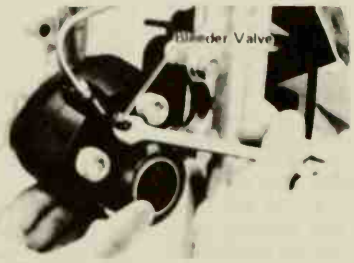
BRAKE PADS

Replacement

1. Read the cautionary notes at the beginning of the "Front Disc Brake" Section.

2. Remove the front wheel as described in the "Wheels Removal and Installation" Section.

3. Remove the mounting screw which secures pad B (see the illustration), and remove the pad.



Removing pad B

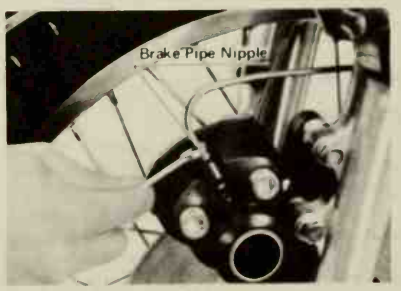
4. Pump the brake lever several times until the piston forces pad A out, and remove the pad.

5. Loosen the bleeder valve slightly, press the piston in by hand as far as it will go, then close the valve.

CAUTION: *Some brake fluid will leak out of the bleeder during this operation. Be prepared to catch it with a rag.*

Opening the bleeder valve reduces the pressure in the caliper slightly

6. On 1975 and earlier models, align the groove in pad A with the ridge in the caliper, then insert the pad. On 1976 models, simply install the pad.

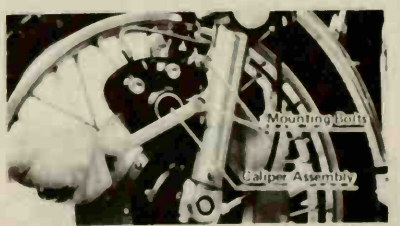


7. Install pad B in the caliper aligning the tongue on the pad with the groove in the caliper on 1976 models, and use either Loctite or some other suitable thread sealer on the mounting screw.

CALIPER (1975 AND EARLIER)

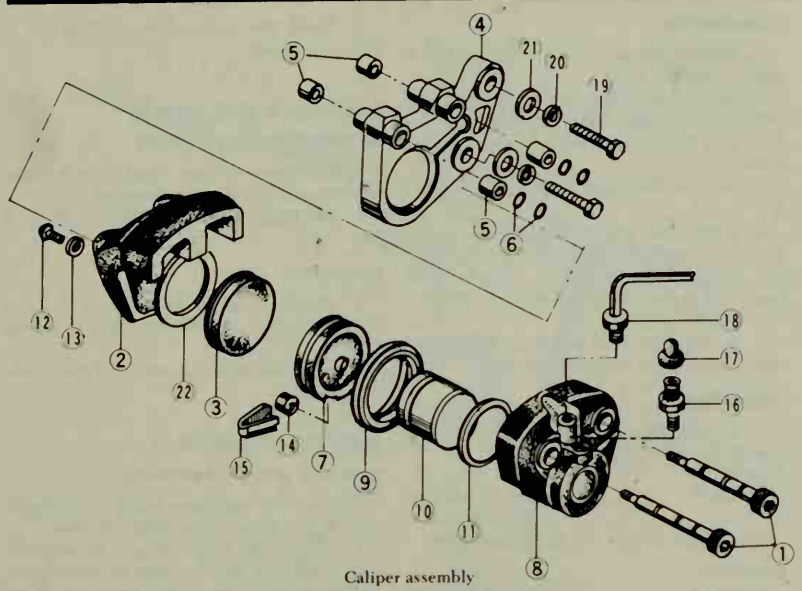
Removal and Disassembly

1. Remove the front wheel.



2. Unscrew the brake pipe nipple and disconnect the pipe.

Loosening the brake pipe nipple



3. If the caliper is to be disassembled, loosen the allen head shafts at this time.

4. Remove the mounting bolts, then remove the caliper.

Removing the caliper

5. Unscrew the allen head shafts (1) evenly, alternating between the two a little at a time, then remove caliper B (2). Pad B (3) may be removed at this time by removing its securing screw (12).

Caliper assembly

1. Allen head shaft
2. Caliper B
3. Pad B
4. Caliper holder
5. Boots
6. O-ring
7. Pad A
8. Caliper A
9. Piston dust seal
10. Piston
11. Seal
12. Screw
13. Lockwasher
14. Bushing
15. Stopper
16. Bleeder valve
17. Bleeder valve cap
18. Nipple
19. Mounting bolt
20. Lockwasher
21. Washer
22. Ring

6. Remove the bolts which secure the caliper holder (4), taking care not to damage the boots (5) or O-rings (6), then remove pad A (7).

7. Remove the two shafts (1) from caliper A (8), then remove the piston dust seal (9) and pull the piston (10) straight out without twisting it. The piston may also be blown out with compressed air through the brake line outlet, if it is reluctant to leave its seat.

8. Remove the seal (11), taking care not to damage the cylinder wall. A special tool (Part No. 56019-111) is available for this job, however a suitable substitute may be used.

Blowing out the piston

Removing the seal

Inspection

1. Inspect the brake pads for damage or excessive wear and replace them as necessary. If the surface of either pad is worn to the red or green warning line, the pads should be replaced, preferably as a pair. Grease or oil on the pads can be removed with triclorethylene or gasoline. If the pads are oil impregnated, they should be replaced.

2. Inspect the oil seals for a worn, damaged, or cracked condition and replace them as necessary. If the seal around the piston, which serves to maintain the proper pad/disc clearance, is bad, one pad will wear more rapidly than the other, and the constant friction caused by the dragging pad will cause a sharp increase in brake and brake fluid temperature which might result in damage to the various assemblies. Replace the seal if any of the following conditions exist:

a. Oil leakage around pad A.
b. The brake overheats under normal conditions.
c. Pad A and B wear unevenly.
d. The seal is stuck to the piston.
e. If the seal has been reused once already.

3. Inspect the caliper and piston for damage or wear past the following specifications, and replace them as necessary:

	Standard	Service Limit
Cylinder inside diameter	1.5031 ~ 1.5039 in. (38.180 ~ 38.200 mm)	1.5045 in. (38.215 mm)
Piston outside diameter	1.5006 ~ 1.5019 (38.180 ~ 38.200 mm)	1.5002 in. (38.105 mm)

4. If there is a mushy feeling at the hand lever when the brake is applied, it may be due to excessive clearance between the caliper halves. This is not a problem concerning braking efficiency, and has only to do with the feeling at the hand lever. Check on this in the following manner:

a. Assemble the caliper as described in the "Assembly and Installation" Section. Be sure that the caliper shafts are torqued to 22–26 ft lbs.

b. Check the clearance between the caliper halves using a 0.012 in (0.30 mm) feeler gauge. If the clearance is greater than this, the caliper must be replaced.

Assembly and Installation

1. Assembly is basically in the reverse order of disassembly. Use new O-rings and fluid seals whenever possible, and use the torque specifications given at the beginning of the "Disc Brake" Section.

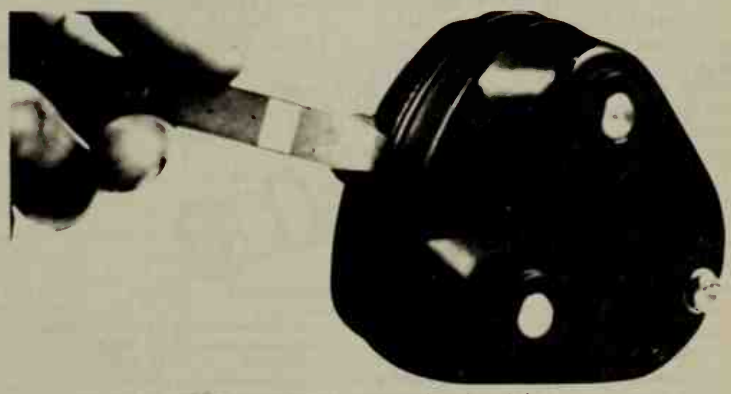
2. Clean all of the caliper components with either brake fluid or alcohol, then coat them all liberally with fresh brake fluid.

3. Bleed the system thoroughly, after it is installed, as described in the "Bleeding the Brake System" Section.

DISC (1975 AND EARLIER)

Removal and Installation

1. Remove the front wheel.



2. Bend down the lockwasher locking tabs, and remove the disc mounting bolts to free the disc for removal.

3. When installing the disc, use new lockwashers whenever possible. Torque the mounting bolts to 104–190 in. lbs (1.6–2.2 kg/m), then bend the locking tab against the flat of the bolt.

Inspection

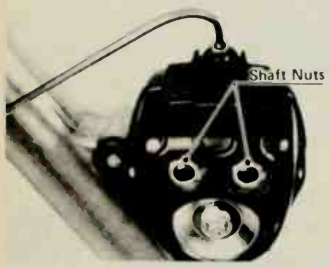
1. Clean any oil off the surface of the disc using either trichlorethylene or gasoline.

2. Inspect the disc for deep score marks or wear, and measure the disc with a micrometer at its most worn part. The disc can be cut safely up to 0.050 in. to remove score marks.

Checking clearance between the caliper halves

Checking the disc for wear

but if the scoring, or wear, runs deeper than the disc's serviceable thickness of 0.217 in. (5.5 mm), the disc must be replaced. Standard thickness for the disc is 0.276 in. (7.0 mm).



3. Check the disc for a warped condition.

If the disc is warped, less than 0.004 in. (0.1 mm) it needn't be replaced, but if it is warped in excess of 0.012 in. (0.3 mm), it must be replaced.

CALIPER (1976 AND LATER)

Removal

1. Remove the front wheel.
2. If the caliper is to be disassembled, loosen the caliper shaft nuts.

Caliper shaft nuts (1976 and later)

3. Disconnect the brake line at the caliper and plug the end with the bleeder valve cap.
4. Remove the caliper-to-fork slider mounting bolts. Remove the caliper.

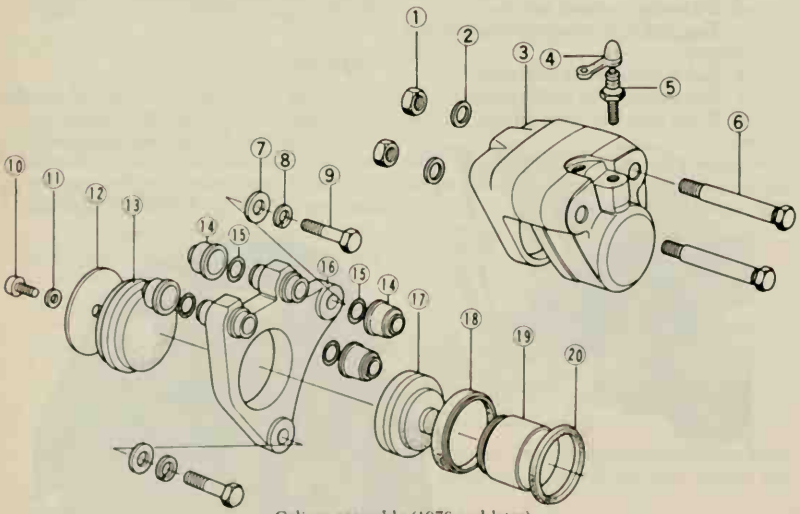
Disassembly

1. Remove the mounting screw for Pad B and remove the pad.
2. Remove the caliper shaft nuts. Carefully pull out the caliper shafts (unscrewing each a little at a time) and spacers. Note the dust covers.
3. Remove the caliper holder. Remove Pad A.
4. Remove the piston dust seal. To remove the piston, apply compressed air at the brake line fitting. If not available, reconnect the brake line to the caliper and apply the brake to force out the piston.
5. Remove the fluid seal from the caliper, taking care not to scratch the walls.

Inspection

1. Check piston and caliper bore diameters against the following:

Bore ID	
Standard	42.850–42.900 mm/ 1.687–1.689 in.
Serviceable limit	42.92 mm/1.69in.
Piston OD	
Standard	42.788–42.820 mm/ 1.685–1.686 in.
Serviceable limit	42.75 mm/1.68 in.



2. Clean all parts in clean brake fluid. The use of new seals is recommended.

Assembly

1. Lubricate all parts with new brake fluid during the assembly process.
2. Lubricate the caliper shafts with PBC (high-temperature, water-resistant) grease.
3. Assembly is the reverse of disassembly. Install the spacers with the protruding side facing in. Tighten caliper shaft nuts after mounting the caliper on the slider.

Installation

1. Tighten the mounting bolts to 25–33 ft lbs.
2. Tighten the caliper shaft nuts to 17.5–20.0 ft lbs.
3. Tighten the brake line fitting to 12–13 ft lbs.

Caliper assembly (1976 and later)

1. Nut
2. Spacer
3. Caliper
4. Bleeder valve cap
5. Bleeder valve
6. Caliper holder shaft
7. Flat washer
8. Lock washer
9. Caliper mounting bolt
10. Mounting screw
11. Lock washer
12. Metal plate
13. Pad B
14. Dust cover
15. O-ring
16. Caliper holder
17. Pad A
18. Dust seal
19. Piston
20. Fluid seal

4. Bleed the system after installation of pads and wheel.

DISC (1976 AND LATER)

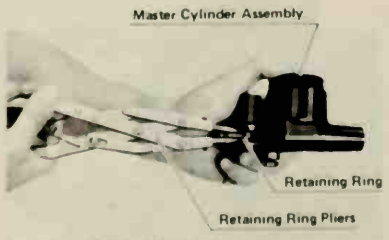
Removal and Installation

1. To remove the disc, bend down the lockwashers and remove the mounting bolts.
2. To install, tighten the bolts to 25–33 ft lbs.

Inspection

1. Standard disc thickness is 6.9–7.1 mm (0.27–0.28 in.). Serviceable limit is 6 mm (0.24 in.).
2. Max. allowable run-out is 0.3 mm (0.012 in.).

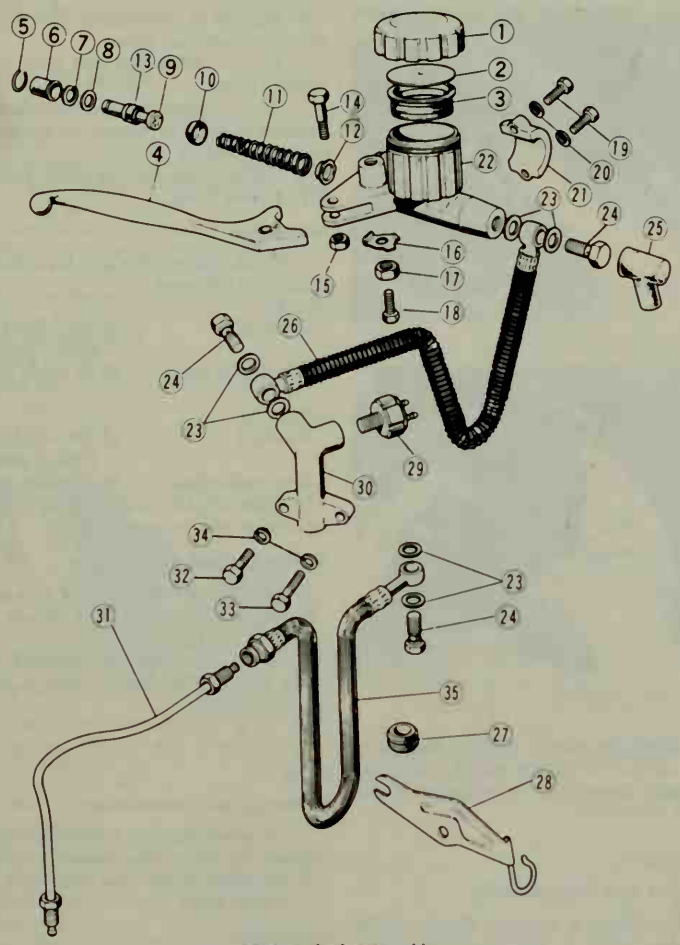
MASTER CYLINDER



Removal and Disassembly

1. Read the cautionary notes at the beginning of the "Front Disc Brake" Section.
2. Remove the right-side rear view mirror.
3. Open the bleeder valve on the caliper, and pump all of the brake fluid out of the system.
4. Remove the banjo bolt which secures the brake line to the master cylinder, then remove the rest of the brake line as desired.
5. Remove the clamp bolts which secure the master cylinder, and remove the cylinder.
6. Remove the reservoir cap (1), diaphragm plate (2), and diaphragm (3), then empty out any residual brake fluid.
7. Remove the brake lever (4), then use either the special tool (Part No. 56019-111) or a suitable substitute to remove the dust cover stopper (5). Remove the dust cover (6).

Removing the dust cover stopper



8. Remove the retaining ring (7) using retaining ring pliers, then remove the stopper (8), piston (9), primary cup (10), spring (11), and check valve (12) from the master cylinder body (22).

Removing the retaining ring

CAUTION: *Do not attempt to remove the secondary cup (13) from the piston as this will damage the cup.*

9. Any remaining components such as the pressure switch (29), the 3-way fitting (30), the

Master cylinder assembly

1. Cap	10. Primary cup	19. Bolt	27. Grommet
2. Plate	11. Spring assembly	20. Washer	28. Bracket
3. Cap seal	12. Check valve assembly	21. Master cylinder mounting	29. Pressure switch
4. Brake lever	13. Secondary cup	22. Master cylinder body	30. 3-way fitting
5. Dust seal stopper	14. Bolt	23. Washer	31. Pipe
6. Dust seal	15. Nut	24. Banjo bolt	32. Bolt
7. Circlip	16. Lockwasher	25. Dust cover	33. Bolt
8. Piston stopper	17. Nut	26. Hose	34. Washer
9. Piston assembly	18. Bolt		35. Hose

brake lines (35) and pipe (31) may be removed at this time.

Inspection

1. Clean all parts in clean brake fluid, then blow them dry. Use compressed air to blow out all passages. A clogged relief port will result in the pads dragging on the disc.

2. Inspect the master cylinder bore and piston for signs of wear, rust, pitting, or damage, and replace as necessary. The master cylinder and piston must also be replaced if worn past their serviceable limit.

3. Inspect the primary and secondary cups for signs of wear, damage, rotting, or swelling, and replace them as necessary. Leaking at the brake lever is an indication of bad cups. The piston must also be replaced if the secondary cup is damaged, however, it's best to replace the cups as a set.

4. Inspect the spring for signs of wear or damage, and replace it as necessary.

5. Replace the rubber dust cover if it is damaged or aged.

6. Inspect the fittings, hoses, and pipes for signs of wear, cracking, rust, or other damage and replace them as necessary.

Measurement	Standard		Service Limit	
	Single Disc	Dual Disc	Single	Dual
Cylinder inside diameter	0.5512 ~ 0.5529 in. (14.000 ~ 14.043 mm)	0.6248 ~ 0.6265 in. (15.870 ~ 15.913 mm)	0.5543 in. (14.080 mm)	0.6280 in. (15.950 mm)
Piston outside diameter	0.5495 ~ 0.5506 in. (13.957 ~ 13.984 mm)	0.6231 ~ 0.6242 in. (15.827 ~ 15.854 mm)	0.5472 in. (13.900 mm)	0.6209 in. (15.770 mm)
Primary, second cup diameter	0.5768 ~ 0.5965 in. (14.650 ~ 15.150 mm)	0.6476 ~ 0.6673 in. (16.450 ~ 16.950 mm)	0.5709 in. (14.500 mm)	0.6417 in. (16.300 mm)
Spring length (free)	2.008 in. (51.0 mm)	1.709 in. (43.4 mm)	1.890 in. (48.0 mm)	1.594 in. (40.5 mm)

7. The necessary specifications for determining the serviceability of the master cylinder components are as above.

Assembly and Installation

1. Assembly is basically in the reverse order of disassembly. Make sure that all internal parts are perfectly clean, and liberally coat them all with clean brake fluid before installing.

2. Make sure that the primary cup and the check valve are not installed backwards, and make sure that they aren't distorted or turned sideways after insertion.

3. Use either the factory tool (Part No. 56019-110) or a suitable substitute to install a new retaining ring in its groove in the cylinder wall. The same tool can be used to install the boot and boot stopper.

4. Install the master cylinder so that the small projection is toward the throttle grip. Secure the lower camp bolts first, then secure the upper bolts. The bolts should be torqued to 55–75 in. lbs (0.63–0.88 kg/m).

Installing the retaining ring

Installing the master cylinder

5. Fill the master cylinder with brake fluid and bleed the system as described in the "Bleeding the Brake System" Section. Do not overtighten the master cylinder cap.

BLEEDING THE BRAKE SYSTEM

A mushy feeling at the brake hand lever can often be traced to air in the brake system. Brake fluid is not easily compressed, so that when the lever is operated, almost all of the force applied to the lever is transmitted to the brake caliper. Air, on the other hand is easily compressed, so that any air in the system quickly compresses before the fluid does. This means that some of the lever travel is used in compressing the air without actually applying force to the caliper, resulting in inefficient braking.

The brake system should be bled whenever the action at the hand lever feels soft or spongy, whenever brake fluid is changed, or whenever a brake line fitting has been loosened or disconnected. Bleed the brake system in the following manner:

NOTE: *Read the cautionary notes at the beginning of the "Front Disc Brake" Section.*

1. Remove the reservoir cap and check that there is plenty of fluid in the reservoir. The fluid level must be checked several times during the bleeding operation, and replenished as necessary. If the fluid in the reservoir runs completely out at any time during the bleeding operation, air will enter the system, and the procedure will have to be begun again.

2. Slowly pump the brake lever until no air bubbles can be seen rising up through the fluid from the holes at the bottom of the reservoir. When no more bubbles appear, the master cylinder end of the brake system has been purged of all air.

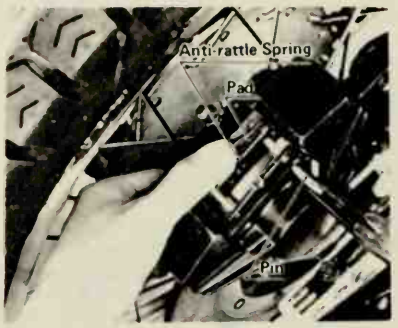
Fill the reservoir to the level line

3. Replace the reservoir cap, and run a clear plastic hose from the caliper bleeder valve into a container. Pump the brake lever until it becomes hard, then, while holding the lever squeezed, quickly open (turn counterclockwise) and close the bleeder valve. Repeat the operation until no more air can be seen coming out into the plastic hose. During this process repeatedly check the fluid level in the reservoir, and replenish it as necessary.

4. If a double disc has been fitted, repeat the above Step on the other side.

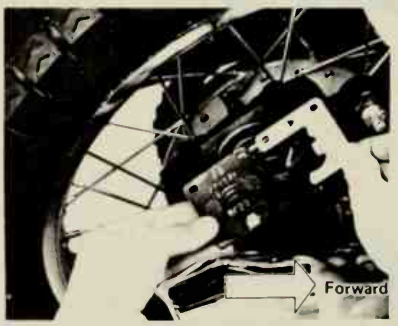
5. When the system has been bled, replace the rubber cap on the bleeder valve(s), and check the fluid level in the reservoir once more. The handlebars must be turned so that the reservoir is level, and the fluid must come up to the level line scribed inside the reservoir.

NOTE: *If twin brakes are used and it becomes difficult to get a firm feeling at the lever, bleed the brake closest to the master cylinder first. Stretching the brake hoses while pumping up the system will help eliminate air bubbles trapped in the system.*



Rear Disc Brakes

Read the preliminary procedures under "Front Disc Brake" before beginning any work.



BRAKE PADS

Replacement

1. Remove the pad cover on the caliper.
2. Remove the two clips from the pins.
3. Hold down the anti-rattle springs and pull out the pins. Remove the pads and shims.
4. To install new pads, remove the bleed valve cap and attach a plastic hose to the nipple, running the other end of the hose into a suitable container.
5. Open the bleed valve slightly and push both pistons in as far as possible using one of the old pads. Close the bleed valve.
6. Insert the pads and shims. Note that each shim is installed so that the triangular hole points towards the front of the motorcycle.

Removing the pad pins

Correct shim installation

7. Check the master cylinder fluid level. Pump up the brake system with the rear brake pedal until operation is normal before operating the motorcycle.

CALIPER

Removal and Disassembly

1. The caliper is removed along with the rear wheel. Refer to the "Rear Wheel (Disc Brake)" removal and installation Section.
2. Remove the brake pads as outlined above.
3. Remove the two caliper allen bolts and separate the caliper halves.
4. Remove the piston dust seals and the caliper O-rings.
5. Apply compressed air to the caliper fluid passages in order to remove the pistons from the caliper halves.
6. Carefully pry out the piston fluid seals with a hooked tool.

Inspection

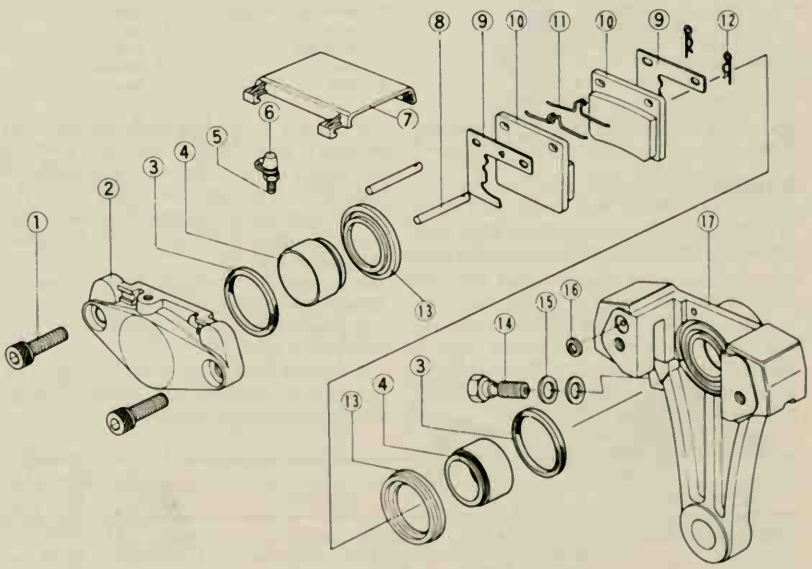
1. Check piston and caliper bore diameters against the following:

Bore ID	
Standard	42.850–42.900 mm/ 1687–1.689 in.
Serviceable limit	42.92 mm/1.69 in.
Piston OD	
Standard	42.788–42.820 mm/ 1.685–1.686 in.
Serviceable limit	42.75 mm/1.68 in.

2. Clean all parts in clean brake fluid. The use of new seals is recommended.

Assembly and Installation

1. Assembly is the reverse of disassembly.
2. Tighten the caliper allen bolts to 20–23 ft lbs (2.8–3.2 kg/m).
3. Install the caliper as outlined in the "Rear Wheel (Disc Bake)" removal and installation Section.



DISC

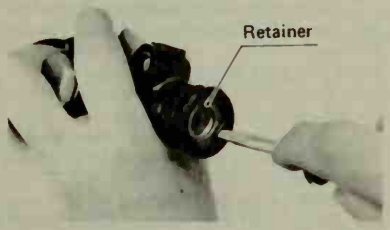
Removal and Installation

1. To remove the disc, bend down the lockwashers and remove the mounting bolts.
2. To install, tighten the bolts to 25–33 ft lbs (3.4–4.6 kg/m).

Inspection

1. Standard disc thickness is 6.9–7.1 mm (0.27–0.28 in.). Serviceable limit is 6 mm (0.24 in.).

Rear caliper assembly



1. Allen bolt
2. Left caliper half
3. Fluid seal
4. Piston
5. Bleed valve
6. Bleed valve cap
7. Pad cover
8. Pin
9. Shim
10. Pad
11. Anti-rattle spring
12. Clip
13. Dust seal
14. Banjo bolt
15. Washer
16. O-ring
17. Caliper body

2. Max. allowable run-out is 0.3 mm (0.012 in.).

MASTER CYLINDER

Removal and Disassembly

1. Remove the right side cover.
2. Disconnect the brake line at the master cylinder, taking adequate precautions to wipe up the brake fluid that spills.
3. Remove the two mounting bolts and remove the master cylinder from the motorcycle.
4. Remove the pushrod dust cover.
5. Remove the master cylinder cap and pour off the brake fluid.
6. Use a thin screwdriver to remove the retainer and take out the piston stopper and piston. Do not remove the secondary cup from the piston as it will be damaged.

Removing the retainer

7. Remove the return spring and primary cup by applying compressed air to the brake fluid outlet hole.

Inspection

1. Clean all parts in clean brake fluid, then blow them dry. Use compressed air to blow out all passages. A clogged relief port will result in the pads dragging on the disc.
2. Inspect the master cylinder bore and piston for signs of wear, rust, pitting, or damage, and replace as necessary. The master cylinder and piston must also be replaced if worn past their serviceable limit.
3. Inspect the primary and secondary cups for signs of wear, damage, rotting, or swelling, and replace them as necessary. Leaking at the brake lever is an indication of bad cups. The piston must also be replaced if the secondary cup is damaged, however, it's best to replace the cups as a set.
4. Inspect the spring for signs of wear or damage, and replace it as necessary.
5. Replace the rubber dust cover if it is damaged or aged.
6. Inspect the fittings, hoses, and pipes for signs of wear, cracking, rust, or other damage and replace them as necessary.
7. The necessary specifications for determining the serviceability of the master cylinder components are as follows:

	Standard	*Service Limit*
Cylinder inside diameter	0.6248 ~ 0.6265 in. (15.870 ~ 15.913 mm)	0.628 in. (15.95 mm)
Piston outside diameter	0.6231 ~ 0.6242 in. (15.827 ~ 15.854 mm)	0.620 in. (15.75 mm)
Cup diameters	0.648 ~ 0.667 in. (16.45 ~ 16.95 mm)	0.642 in. (16.30 mm)
Spring free length	1.62 in. (41.2 mm)	1.54 in. (39.0 mm)

Assembly and Installation

1. Assembly is the reverse of disassembly. Be sure the spring is installed with the spring seat side facing out.
2. Be sure that the primary cup is properly inserted and not turned or installed backwards.

Rear Hub

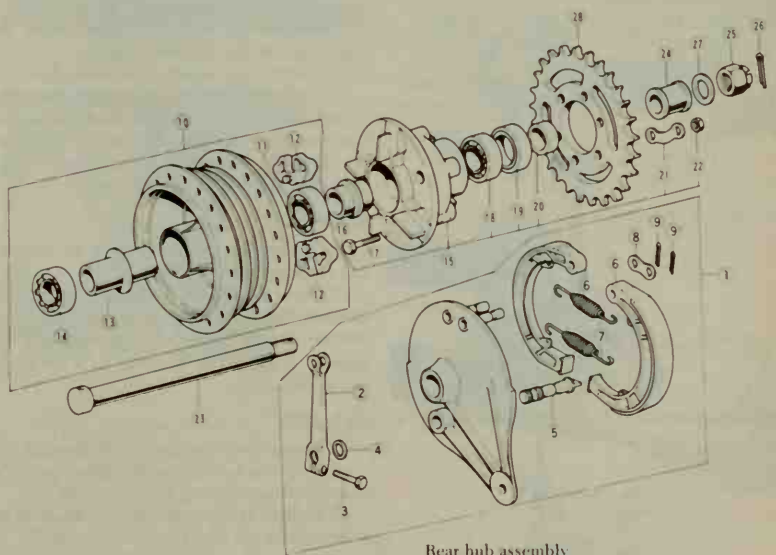
DRUM BRAKE

Disassembly

1. Remove the rear wheel as described in the "Wheels Removal and Installation" Section. Refer to the accompanying illustration.
2. Remove the axle nut (25), washer (27), and distance collar (24), then remove the axle (23) by withdrawing it through the left side.
3. Remove the panel assembly (1) from the hub (10) then disassemble the panel assembly in the following manner:
   a. Remove the two cotter pins (9) and double washer (8) which secure the brake shoes.
   b. Use a punch to mark the original position of the brake cam lever (2) and the brake cam (5), then remove the pinch bolt (3) and lever.

   NOTE: *Lever removal can be made easy by using a screwdriver to pry at the pinch bolt slot while pulling the lever off the cam.*
   c. Remove the dust seal (4), then remove the brake shoes (6) and cam (5) by prying the shoes up evenly and removing them along with the cam.
   d. Remove the brake return springs (7) from the shoes.
4. Separate the coupling assembly (15) from the hub (10), then disassemble it in the following manner:
   a. Remove the shock damper rubbers (12), distance collar (16), axle sleeve collar (20), and oil seal (19).
   b. Tap evenly around the bearing (18) inner race from the inside of the coupling assembly (15) with a suitable drift until the bearing comes out.
5. Tap evenly around the inner race of the panel side bearing (14) from the sprocket side until it comes out, remove the distance collar (13), then tap evenly around the inner race of the coupling assembly side bearing (11) from the panel side until it comes out.
6. The rear sprocket (28) can be removed by bending up the lockwasher locking tabs, and removing the mounting nuts and bolts.

   NOTE: *If just the sprocket is to be removed it is not necessary to disassemble the hub. Remove the left-side mufflers, the sprocket mounting bolts, the rear wheel, and then the sprocket.*



Inspection

1. Clean all parts, other than the brake shoes, seals, and rubber dampers in a suitable solvent, then blow them dry.
2. Inspect the brake drum for a warped, scored, or damaged condition, and replace it as necessary. Measurements should be taken in no less than two different places. If the drum is scored or worn out of round it can be turned down as long as turning it doesn't exceed the specified limits which are as follows:

Measuring the rear hub

Standard	*Service Limit*
7.874 ~ 7.881 in. (200.00 ~ 200.185 mm)	7.904 in. (200.75 mm)

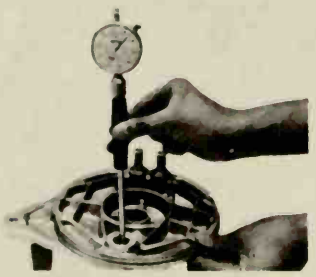
Rear hub assembly

1. Panel assembly
2. Brake cam lever
3. Bolt
4. Dust seal
5. Brake cam
6. Brake shoe
7. Spring
8. Double washer
9. Cotter pin
10. Drum assembly
11. Bearing
12. Shock damper rubber
13. Spacer
14. Bearing
15. Coupling
16. Distance collar
17. Bolt
18. Bearing
19. Oil seal
20. Sleeve collar
21. Washer
22. Nut
23. Axle
24. Distance collar
25. Nut
26. Cotter pin
27. Washer
28. Rear sprocket

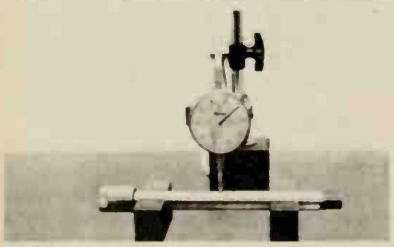
3. Inspect the brake shoes for excessive or uneven wear, or for oil or grease impregnation, and replace them as necessary. Surface glazing or high spots can be removed by sanding. The shoes should be measured in several spots, and they must be replaced if worn anywhere past their serviceable limits which are as follows:

Standard	Service Limit
0.1909 ~ 0.2146 in. (4.85 ~ 5.45 mm)	0.118 in. (3.00 mm)

4. Inspect the brake return springs for a worn, pitted, collapsed, or otherwise damaged condition, and replace them as necessary. The brake spring free length specifications are as follows:



Standard	Service Limit
2.62 in. (66.5 mm)	2.72 in. (69.0 mm)



Measuring the brake camshaft

5. Inspect the brake camshaft and backing plate for signs of wear or damage, and replace them individually or as a pair as necessary. These measurements are critical if efficient braking is to be maintained, and therefore should be done with micrometers as illustrated. The service limits for these items are as follows:

	Standard	Service Limit
Camshaft	0.6676 ~ 0.6687 in. (16.957 ~ 16.984 mm)	0.6626 in. (16.83 mm)
Shaft hole	0.6693 ~ 0.6704 in. (17.000 ~ 17.027 mm)	0.6764 in. (17.18 mm)

Measuring the inside diameter of the camshaft hole

Measuring rear axle run-out

6. Measure the rear axle run-out in the manner indicated, and replace it if run-out exceeds 0.008 in. (0.2 mm).

7. Inspect the rubber dampers for signs of cracking, damage, or rotting, and replace them as necessary.

Assembly

1. Assembly is in the reverse order of disassembly. Use new oil seals, locking tabs, and cotter pins whenever possible.

NOTE: *The small cotter pins which secure the brake shoes to the backing plate are sometimes difficult to locate. In a case like this, mechanic's wire will work as a substitute. Loop it through the holes in the pivots at least twice.*

2. Use either the special factory tools (Part Nos. 57001-139 and 57001-140), or a suitable substitue, when installing the bearings and oil seals.

3. When installing the rear sprocket, torque the mounting nuts to 23–30 ft lbs (3.1–4.2 kg/m), and bend the locking tab up against a flat of the nut.

4. Lubricate the brake pivots, brake shoe anchor pins, brake return spring ends, and the brake camshaft surface and groove with grease. Be sure that the camshaft groove is filled, but take care not to overlubricate, as this may result in grease on the brake shoes and drum.

DISC BRAKE

Disassembly

1. Remove the rear wheel from the motorcycle. Remove the axle and brake caliper.

2. Remove the sprocket nuts and washers. Remove the sprocket from the coupling.

3. Separate the sprocket coupling from the wheel hub.

4. Remove the coupling collar from the left and the coupling sleeve from the right of the coupling.

5. Pry out the bearing grease seal. Remove the circlip and tap out the bearing from the wheel side of the coupling.

6. Remove the rubber dampers from the hub. Remove the disc-side collar.

7. Unbolt and remove the brake disc.

8. Pry out the grease seal on the disc side, remove the circlip, and reach through the hub from the disc side to tap out the left-side bearing. Remove the wheel bearing spacer. Remove the other bearing in the same manner.

Inspection

1. Check the rubber dampers for damage and replace them if necessary.

2. Clean the wheel bearings in a solvent, oil them lightly, and check operation. Bearing rotation should be smooth, noiseless, and effortless. Replace the bearings as a set if any one is damaged.

Assembly

1. Assembly is the reverse of disassembly.

2. Pack the bearing with a good grade of bearing grease. Use new grease seals.

3. Tighten the sprocket nuts to 25–33 ft lbs (3.4–kg/m).

FINAL DRIVE

Removal

NOTE: *The drive chain may be cut or broken with a chain breaker if it is going to be discarded and replaced. Otherwise, the chain must never be cut.*

1. Remove the chain cover in the following manner:

a. Remove the chain oil pump cover screws and cover on models so equipped.

b. Slide back the hose clamp and disconnect the inlet hose from the pump. One of the cover screws can be used to plug the hose to prevent oil leakage.

c. Remove the left footrest and shift pedal. The clamp bolt must be completely removed before the shifter can be removed.

d. Remove the starter cover and cover gasket.

e. Remove the chain cover mounting bolts, then remove the cover.

f. Remove the cotter pin from the clutch release lever, and disconnect the clutch cable.

2. Loosen the cylinder exhaust flange bolts and the muffler mounting bolts for the two left-hand mufflers, and either remove or swing the pipes up out of the way.

3. Remove the lower mounting bolt from the left-side rear shock absorber.

4. Loosen the chain adjusters and back off the adjusting nuts so that the chain is as loose as possible.

5. Remove the rear axle cotter pin, loosen the axle nut, and push the rear wheel forward in the swing arm.

6. Remove the engine sprocket in the following manner:

a. Remove the clutch pushrod and sprocket guard.

b. Bend back the lockwasher locking tab.

c. Secure the sprocket so that it won't turn by using the special tool (Part No. 57001-118), a suitable substitute, or by engaging the transmission in Low gear, then remove the sprocket and disengage the chain.

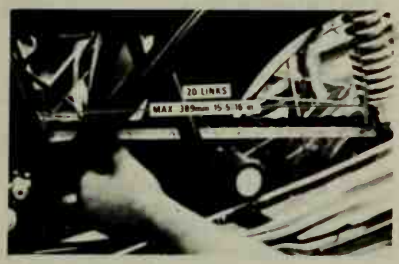
7. Disconnect the rear brake torque link at the rear hub, remove the brake rod adjusting nut and disconnect the rod from the lever by rotating the brake backing plate, and remove the two pinch bolts and stoppers at the swing arm chain adjusters.

NOTE: *Remove the spring and link pin from the brake lever and put them back on the rod to avoid losing them.*

8. Push the left shock absorber out of the swing arm, loop the chain over the swing arm, and slide the rear wheel out of the swing arm.

9. Remove the nut from the swing arm pivot shaft, and withdraw the shaft. Tilt the swing arm until the pivot section clears the frame, then drop the chain through the gap.

Inspection



1. Check the drive chain for signs of wear, cracks on the rollers, bushings, or roller links, or for kinking or binding, and replace it if any of these conditions exist. Thoroughly lubricating the chain may help free kinked or bound links.

2. Replace the chain if it is worn more than 2% of its original length. This can be determined by measuring the chain in either of the following manner:

a. Stretch the chain taut by using the chain adjusters, or by hanging a 20 lb (10 kg) weight on the bottom run of the chain.

b. Remove the chain guard and measure the length of 20 links along a straight line from the center of the first pin to the center of the twenty-first pin.

c. If the length of the chain exceeds the standard length of 15.0 in. (381 mm) by more than 5/16 in. (8 mm), the chain must be replaced.

Measuring the chain

3. Inspect both the drive (engine) and driven sprockets for signs of wear, damage, or a warped condition, and replace them as necessary if worn past the service limits given below:

a. Engine sprocket diameter:

900

Standard	Service Limit
3.376 ~ 3.384 in. (85.76 ~85.96 mm)	3.346 in. (85.0 mm)

1000

Standard	Service Limit
3.11 ~ 3.12 in. (79.01 ~ 79.21 mm)	3.08 in. (78.3 mm)

b. Rear sprocket diameter and run-out:

900

Diameter		Runout	
Standard	Limit	Standard	Limit
8.560 in. (217.4 mm)	8.484 in. (215.5 mm)	under 0.012 in. (under 0.3 mm)	0.020in. (0.5 mm)

1000

Diameter		Runout	
Standard	Limit	Standard	Limit
7.39 ~ 7.41 in. (187.77 ~ 188.27 mm)	7.38 in. (187.4 mm)	under 0.012 in. (under 0.3 mm)	0.020in. (0.5 mm)

Measuring rear sprocket diameter

Installation

1. Installation is basically in the reverse order of removal.

2. Make sure that the chain adjustment is loose enough to allow the engine sprocket and chain to fit properly, then readjust it afterwards.

3. Make sure that the lockwasher tab seats in the hole in the sprocket, and bend up one side of the washer after securing the sprocket nut.

4. Secure the sprocket nut to 87–108 ft lbs (12–15 kg/m).

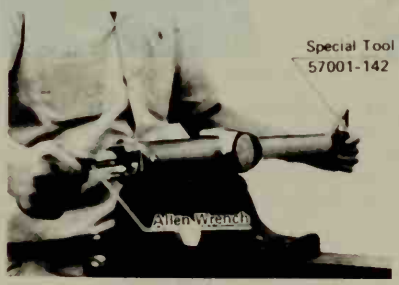
5. Use an oil seal guide (Part No. 57001-130) to prevent damage to the seal while installing the chain cover.

6. Rotate the rear wheel until the pin inside the output shaft and the groove in the chain oil pump shaft are in alignment before installing the cover.

FRONT FORKS

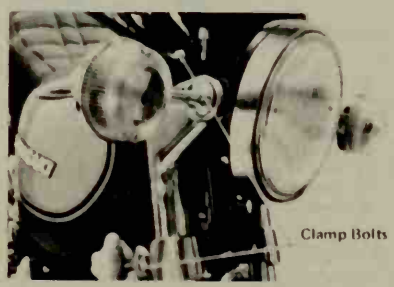
Fork Tubes

REMOVAL AND DISASSEMBLY



1. Remove the front wheel as described in the "Wheels Removal and Installation" Section.

2. Remove the front fender mounting bolts and fender.



3. Remove the brake caliper and place it out of the way.

NOTE: *The caliper need not be disconnected from the brake line pipe, however the assembly should be tied to or rested on something to avoid bending the pipe.*

4. Remove the bolt (2) from the top of the tube if the fork is to be disassembled once it's removed. If only the slider is to be removed, it may be done now by removing the allen bolt (30) from the bottom.

Disassembling the fork tube and slider

Clamp bolt locations

NOTE: *If you've removed or loosened the top bolt (2), the cylinder assembly (19) will rotate and you won't be able to remove the allen bolt without the assistance of the special factory tool (Part No. 57001-142).*

5. If you wish to remove the entire fork leg, remove the top bolt (2) and the clamp bolts (6 and 16), and pull the assembly down and out. If you use screwdrivers to spread the clamps on the stem head (4) and stem (15) assemblies the legs will come out more easily.

6. Invert the assembly and dump out the spring (18) and fork oil. If the allen bolt (30) has been removed, the inner tube assembly (19) will also come out.

7. Remove the circlip (36) from the inner tube using snap-ring pliers, and remove the cylinder assembly (20) from the tube.

8. Remove the dust seal (21) from the outer tube (25), then remove the circlip (22) and oil seal (24) using a sharp hook.

NOTE: *Once the oil seal has been disturbed it must be replaced.*

INSPECTION

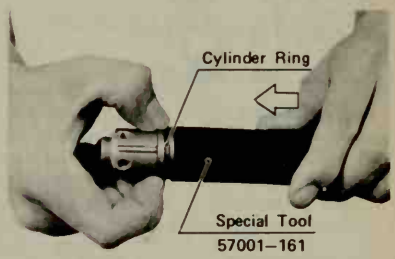
1. Clean all of the components in a suitable solvent, then blow them dry.

2. Inspect all parts for signs of wear, scoring, stripped threads, warpage, or other damage and replace them as necessary.

3. Inspect the inner tube for a bent condition by rolling it across a flat surface, and have it straightened out if it isn't too severely bent.

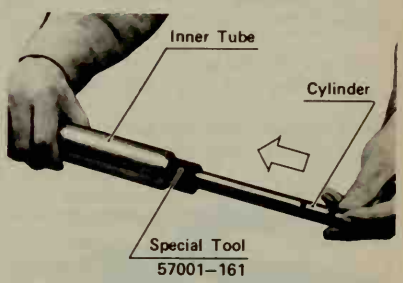
4. Inspect the spring for a collapsed or damaged condition, and measure it to check its free length. If the spring is shorter than 19.09 in. (485 mm) for the 900 or 17.91 in. (455 mm) for the 1000 it must be replaced.

NOTE: *If one spring is shorter than its serviceable limit, and the other is only marginally above the limit, it's a good idea to replace them both at this time.*



ASSEMBLY AND INSTALLATION

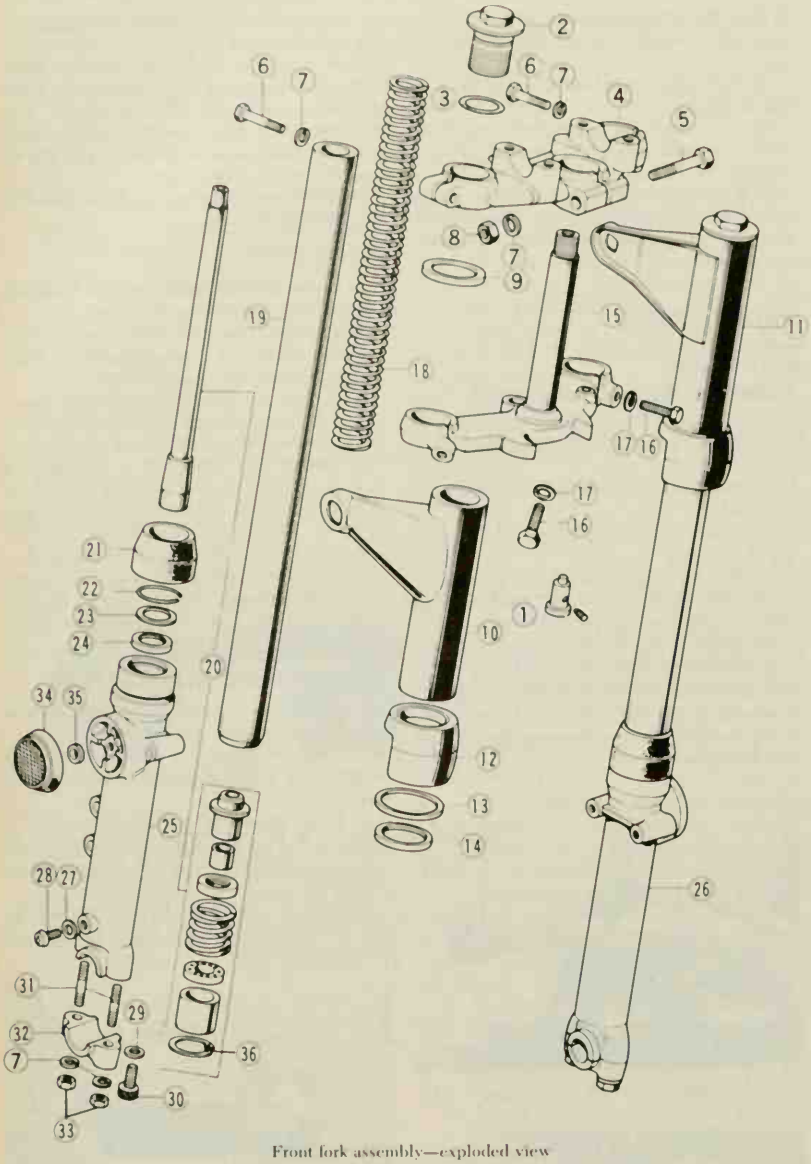
1. Assembly is basically in the reverse order of disassembly. Use new seals.



On 1974–76 forks, use the special tool for inserting the cylinder assembly into the inner tube.

2. When installing new oil seals, use the special tool (Part No. 57001-141) to install the seal. Lubricating the seal will make installation easier.

If progressively-wound fork springs are fitted, install them with the close coils toward the top of the forks.



Assembling the damper components with the special tool (1974–76)

Assembling the fork tube (1974–76)

3. Before tightening the top clamp, make sure that the flange surface of the bolt in the top of the tube is level with the top of the steering stem.

4. Secure the upper clamp bolt to 140–155

Front fork assembly—exploded view

1. Lock assy	10. Headlight stay	19. Inner tube	28. Drain plug
2. Top bolt	11. Headlight stay	20. Cylinder	29. Gasket
3. O-ring	12. Stay guide	21. Dust seal	30. Allen bolt
4. Stem head	13. Washer	22. Circlip	31. Stud
5. Clamp bolt	14. Gasket	23. Washer	32. Axle
6. Clamp bolt	15. Steering stem	24. Oil seal	33. Nut
7. Lockwasher	16. Bolt	25. Outer tube	34. Reflector
8. Nut	17. Lockwasher	26. Outer tube	35. Rubber washer
9. Washer	18. Spring	27. Gasket	36. Circlip

in. lbs (1.6–1.8 kg/m), and the lower clamp bolt to 40–43 ft lbs (5.4–6.0 kg/m).

STEERING STEM

Removal

1. Remove the front wheel as described in the "Wheels Removal and Installation" Section.

2. Remove the fender mounting bolts and fender.

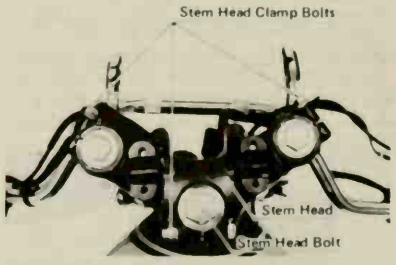
3. Remove the bolt from the bottom of the headlight shell and the two screws from the sides, which serve to secure the beam assembly, and remove and unplug the beam assembly.

4. Unplug the turn signal wires, and disconnect the main wiring harness connectors.

5. Remove the turn signals and headlight shell after removing the mounting hardware.

6. Disconnect the tachometer cable at the cylinder head.

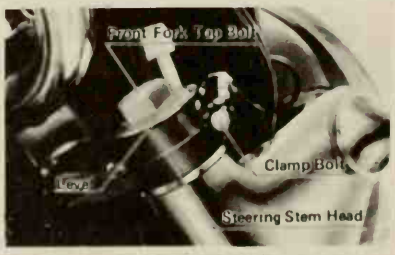
7. Remove the mounting bolts which secure the instrument and ignition switch cluster, and remove the assembly. Remove the gas tank.



8. Remove the mirrors (if applicable), then disconnect the front brake pressure switch wires.

9. Remove the mounting bolts for the master cylinder, the 3-way fitting, and the caliper, then remove the entire brake system while taking care not to damage the brake line pipe.

10. Unbolt the handlebars and allow them to rest on the tubes as illustrated, then loosen



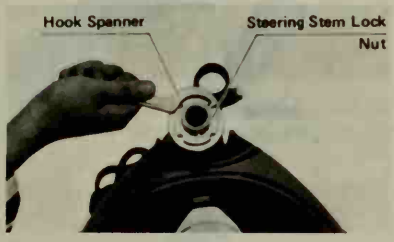
Removing the instrument cluster mounting bolts

Clamp bolt locations

Installing the oil seal

Lining up the tube in the triple clamp

Removing the lower clamp bolts



the 3 stem head clamp bolts, remove the stem head bolt, and remove the stem head.

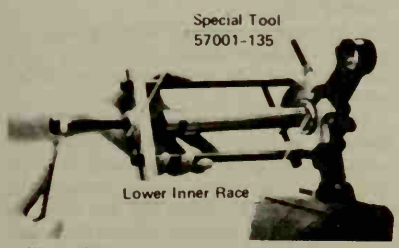
11. Rest the handlebars on the frame, remove the two lower clamp bolts, the fork ears (headlight stay), and the fork tubes.

12. Remove the steering stem locknut using a suitable hook spanner, and drop the stem out from the bottom. Remove the stem cap, upper inner race, and the bearings.

CAUTION: *When withdrawing the stem, be prepared to catch the lower race bearings in a suitable receptacle. Always keep the two bearing groups separate for installation in their original locations.*

13. Remove the bearing races; only if they must be replaced, by drifting them out with a suitable soft face drift. Drove the lower race out from the top, and the upper race out from the bottom. Tap evenly around the circumference of the race while removing the races.

Removing the stem locknut



Removing the steering stem

Drifting out the lower race

14. Pull off the lower race which is pressed onto the steering stem by using either the special tool (Part No. 57001-135) or a suitable substitute. Try not to damage the grease seal under the race, or stretch it and pull it off over the race.

Pulling off the stem lower race

Inspection

1. Clean all parts, other than gaskets and seals, in a suitable solvent, and blow them dry.

2. Inspect all parts for signs of wear, stripped threads, or damage, and replace them as necessary.

e. Visually inspect the stem for a tilted condition and replace it if not perpendicular to the clamp.

4. Inspect the bearings and races for signs of wear, scoring, or damage, and replace them as complete sets as necessary. Bright spots on the inner portion of the race indicate advanced wear, and may cause jerky steering.

Installation

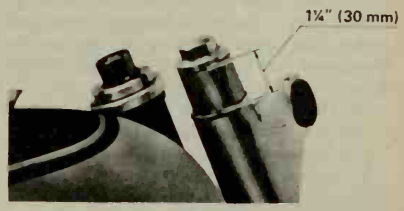
1. Installation is basically in the reverse order of removal.

2. Liberally oil the outer races and drive them into the head pipe using either the special tools (Part Nos. 57001-139 and 57001-138) or a suitable substitute such as a soft-faced drift. Be sure that they seat evenly in the pipe.

Installing the races using the special tools

3. Oil the lower inner race and drive it into the stem using either the special tool (Part No. 57001-137) or a suitable substitute. The race can be driven on using the clamping edges of a vise if necessary, but this is hard on the bottom of the clamp.

Driving on the lower inner race



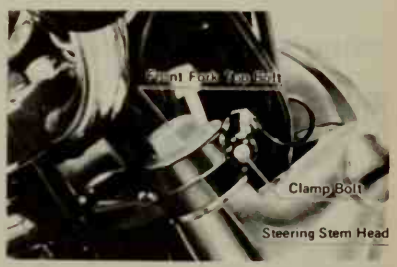
NOTE: *If the special tools are being used, install a new seal before driving on the race. If you are going to drive it on using the edges of a vise, it's best to drive on the race and then stretch the seal on over the race.*

4. Liberally grease the bearing races, and stick the bearings in the grease. The upper race takes 19 bearings, and the lower race takes 20.

5. Insert the stem into the frame head, then install the upper inner race, cap, and locknut.

6. Use a suitable hook spanner to tighten the locknut until the stem moves smoothly and freely to either side, but no play exists in the bearings.

7. Position the fork ears and guides between the two halves of the stem assembly, then slide the fork tubes up through them so that they protrude about 1¼ in. (30 mm) at the top. Snugging up the lower clamp bolt will hold the tubes in position.



Fork tubes properly positioned

8. Position the handlebar assembly as illustrated, making sure that all the wires and cables are correctly routed.

9. Install the stem head, and secure the stem head bolt and the rear clamp bolt.

10. Loosen the lower clamp bolt, position the fork tube so that the flange surface of the fork top bolt is flush with the upper surface of the steering stem head, then secure the upper and lower clamp bolts. The 3 upper clamp bolts should be secured to 140–155 in. lbs (1.6–1.8 kg/m), and the two lower clamp bolts

Fork tubes ready to be secured

should be torqued to 40–43 ft lbs (5.4–6.0 kg/m).

NOTE: *Secure the lower clamp bolts first, then the upper bolts.*

11. Mount and bleed the disc brake assembly as described in the "Front Disc Brake" Section.

12. Mount and secure the ignition switch and instrument cluster, then mount, but do not secure, the headlight shell and turn signals.

13. Start, but do not tighten, the bolt which goes in the bottom of the headlight. Adjust the vertical height of the shell, then secure the shell, the bottom bolt, and the turn signals.

14. Connect the wiring harness connectors, then connect and install the headlight lamp unit.

NOTE: *The left turn signal lead goes to the green wire, and the right lead goes to the gray wire.*

15. Mount and secure the front fender, the brake hose clamp, and the front wheel.

REAR SHOCK ABSORBERS

Removal, Disassembly and Installation

1. Remove the mounting nut from the upper end, and the bolt from the lower end of each shock. If there is not sufficient clearance for the removal of the bottom mounting bolt,

it will be necessary to loosen or remove the mufflers on the side in question.

2. Remove the mounting bolts for the chrome bar, and remove the bar, then pull the shock free of the mounting stud.

3. Disassemble the shock by compressing it until the upper keepers are free to be removed, then remove the keepers, cover, and spring. The upper mounting eye can now be unscrewed and removed if it or the rubber stopper is to be replaced.

NOTE: *The shock can be compressed in a vise or by pressing it against the floor while someone else removes the keepers.*

4. Assembly and installation are in the reverse order of removal and disassembly. If you want to look racy, it's not necessary to replace the cover.

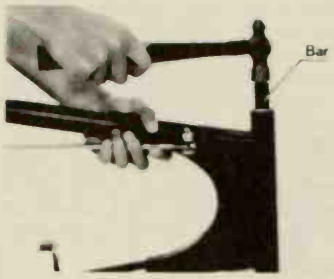
Inspection

1. Once the shock is disassembled, check its dampening action by pushing in the piston rod, and then pulling it back out. The rod should slip smoothly in until seated, and should take more effort to pull it back out than to push it in. Both shocks should react to this test in the same manner.

2. Replace the shocks, preferably as a set, if one or both fails the above test, if the seals leak, or if the rod is bent.

SWING ARM

900



REMOVAL AND DISASSEMBLY

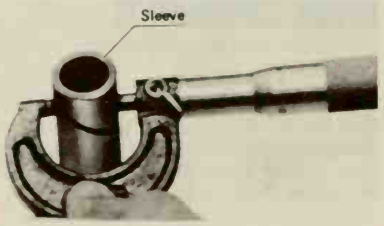
1. Remove the rear wheel as described in the "Wheels Removal and Installation" Section.

2. Remove the rear shock absorber lower mounting bolts, then unscrew the swing arm pivot shaft nut, withdraw the shaft, and remove the swing arm.

3. Pull the sleeve (5) out of each end of the swing arm.

4. Position the distance collar (9) so that it seats against either bushing (6), or at least so it's off center, then, using a suitable bar as a drift, gently drift out the opposite side bushing. Invert the swing arm and remove the remaining bushing.

Drifting out a bushing

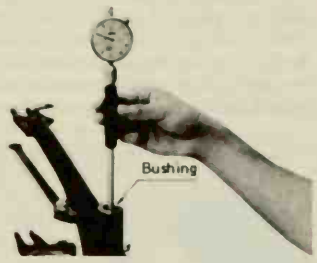


INSPECTION

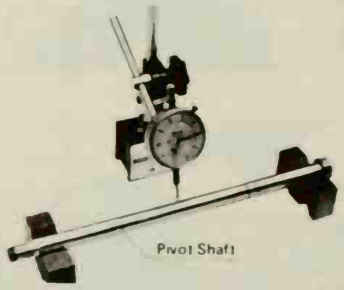
1. Clean all parts in a suitable solvent, then blow them dry.

2. Inspect the swing arm for stress signs, cracks, bends, or other damage, and have it repaired or replace it as necessary.

NOTE: *Any necessary welding should be done by a professional to assure rigidity and correct alignment.*



3. Inspect the sleeves for signs of wear or damage, and replace them as a set if either is in need of replacement. The standard outside diameter of a sleeve is 0.8653–0.8661 in. (21.979–22.171 mm), and the sleeve must be replaced if worn past its serviceable limit of 0.864 in. (21.95 mm).



Measuring a sleeve for wear

4. Inspect the bushings for signs of wear or damage, and replace them as a set if either is in need of replacement. The standard inside diameter of a bushing is 0.8712–0.8729 in. (22.128–22.171 mm), and the bushing must be replaced if worn past its serviceable limit of 0.881 in. (22.37 mm).

5. Inspect the pivot shaft for signs of wear, scoring, excessive run-out, or other damage, and replace it as necessary. Check the run-out with a dial indicator and a pair of V-blocks as illustrated. If the run-out exceeds the standard allowance of under 0.004 in. (under 0.1 mm), the shaft must be straightened or replaced.

Measuring a bushing

Checking the pivot shaft run-out

ASSEMBLY AND INSTALLATION

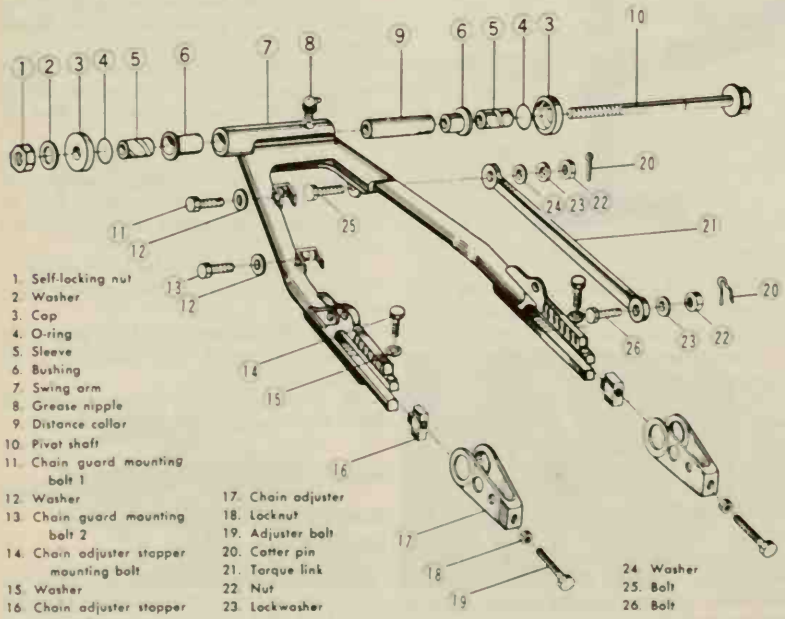
1. Assembly is in the reverse order of disassembly, and installation is in the reverse order of removal. New O-rings and bushings should be used whenever possible, and the bushings should be oiled before being installed.

2. Thoroughly grease the swing arm by applying grease through the grease nipple until it runs out either end of the swing arm, then wipe off the excess.

3. Secure the pivot shaft to 87–108 ft lbs (12–15 kg/m).

1000

REMOVAL AND DISASSEMBLY



1. Remove the mufflers. Remove the rear wheel.

2. Detach the brake hose from the swing arm clips.

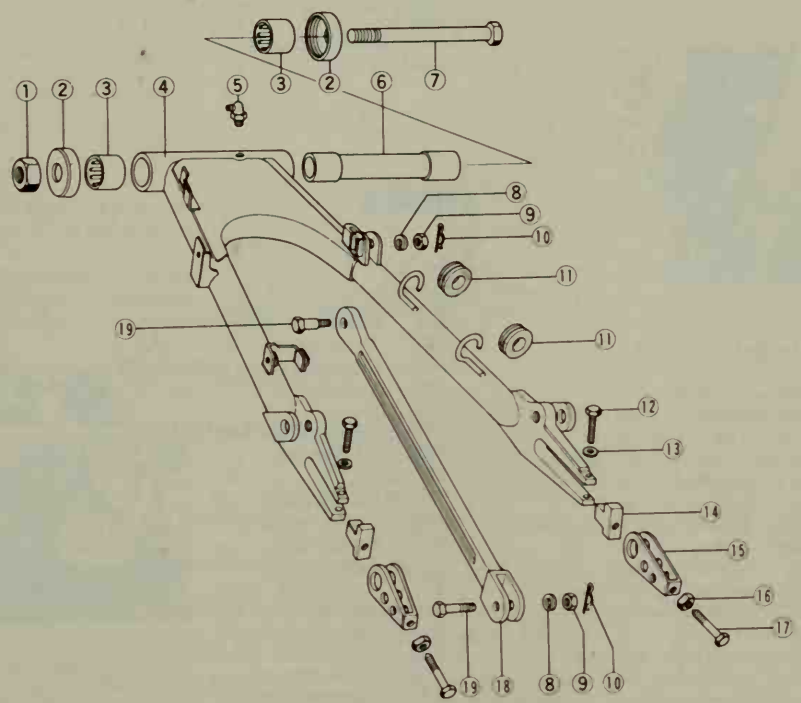
3. Remove the lower mounting bolt of each shock absorber.

4. Remove the swing arm pivot shaft nut and pull out the pivot shaft. Remove the swing arm. Note the dust cap on either end of the swing arm.

5. The swing arm needle bearings will be damaged on removal. Be sure to have new ones on hand prior to disassembly. Pull out the swing arm sleeve. Reach through the swing arm with a suitable drift and drive out one of the needle bearings. Repeat the procedure with the other.

Swing arm—exploded view

INSPECTION



1. Measure the outside diameter of the swing arm sleeve at both ends. Standard diameter is 0.8656–0.8661 in. (21.987–22.000 mm). Service limit is 0.8646 in. (21.96 mm). Replace the sleeve and both bearings if it is worn beyond this limit.

2. Check the pivot shaft for a bent condition and replace it if it is bent more than 0.008 in. (0.2 mm).

ASSEMBLY AND INSTALLATION

1. Assembly is the reverse of disassembly. Lubricate the needle bearings with oil before installation, then apply chassis grease to the grease nipple until some shows at both ends of the swing arm.

2. Tighten the pivot shaft nut to 58–87 ft lbs (8.0–12.0 kg/m).

MAINTENANCE

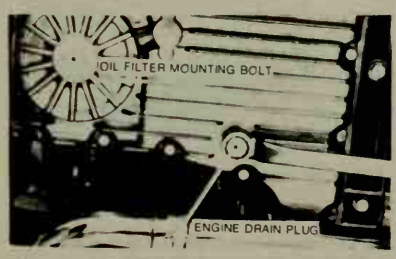
NOTE: *Common maintenance procedures are explained in detail in the "General Information" section.*

LUBRICATION

Motor Oil

For use in all temperatures, Kawasaki recommends SAE 10W-40 motor oil, service rating "SE." SAE 10W-50 or 20W-50 can also be used.

Checking Oil Level

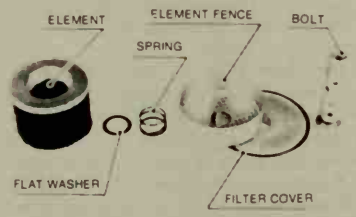


1. The KZ650/750 has a wet-sump lubrication system, all of the oil being contained in the crankcases.
2. A sight glass is provided just below the clutch housing on the right side of the engine to allow oil level to be checked.

3. Be sure that the motorcycle is parked on the center stand and on a level surface.
4. If the engine has just been shut off, allow it to sit for a few minutes before checking the level.
5. With the above conditions met, the oil level should be between the upper and lower level marks inscribed by the inspection glass. If the level is too low, add enough oil to bring the level up even with the top level mark. If the oil level is too high, siphon some of the excess off. Do not overfill the crankcase.
6. If the oil and filter have just been changed, the engine should be allowed to idle for several minutes before checking the level to give the filter case a chance to fill up.

Changing Oil

1. The recommended oil change interval is 1800 miles or three months, whichever comes first.
2. Oil should be changed when the engine is warm. This ensures more complete draining, and makes it more likely that the oil will carry off any particulate matter with it.



Removing the drain plug

3. With the motorcycle parked on the center stand, and a suitable container (at least 3½ qt. capacity) placed beneath the engine, remove the crankcase drain plug and allow the oil to drain off. After draining seems to be complete, kick the engine over a few times with the kickstarter to drain off the oil in the filter. This is not necessary if the filter is being changed at the same time.
4. Install the drain plug and tighten it to 10–12 12 ft lbs.
5. If the filter is being changed, refer to "Oil Filter," below.
6. Add about 3.2 qts. (3.0 l) of SAE 10W-40, 10W-50 or 20W-50 oil to the crankcase. Start the engine and allow it to idle for a couple of minutes. Shut it off, let it sit a few minutes more, then check the oil level. Add oil, if necessary, to bring the level up to the upper level mark.

If the filter is being changed at the same time, it will be necessary to add more oil (3.7 qts./3.4 l). See the following section.

Oil Filter

1. The oil filter should be changed at every other oil change (3600 miles/6 months).
2. Proceed as outlined above ("Changing Oil," Steps 2–4). Place the container beneath the oil filter.
3. Remove the oil filter mounting bolt and take out the filter.
4. Hold the filter element steady and twist out the filter bolt.
5. Check the condition of the filter bolt and filter cover O-rings. If they are knicked, flattened, hardened, discolored, or otherwise damaged, the O-rings should be replaced.
6. Before fitting the new filter element, lightly oil the grommets on both sides. When installing the element onto the filter bolt, be sure that the grommets do not slip out of place.

Oil filter components

7. Wipe off the large o-ring's mating surface on the crankcase. Lightly oil the large o-ring and the filter bolt o-ring.
8. Install the filter assembly and tighten the bolt to 13–16 ft lbs.
9. Add 3.7 qts. (3.5 l) of the proper grade of oil to the crankcase and check the oil level as previously described.

NOTE: *If the filter components have been completely disassembled, the correct reassembly order is: filter bolt, filter cover, element fence, spring, flat washer, and filter element.*

Front Forks (Standard)

1. SAE 10W oil is recommended for KZ650-B front forks, SAE 15W for other models.
2. Fork oil should be changed every 6000 miles or 12 months, whichever comes first.
3. Place a container beneath one of the fork sliders and remove the drain plug. Pump the slider up and down by applying the front brake and pushing on the forks until all of the old oil is expelled. Examine the plug gasket, replacing it if it is damaged, then refit the plug.

Removing the fork drain screw

Repeat the procedure with the other fork slider.

4. Examine the drained oil. If it contains water, or is exceptionally dirty, it may be that the dust covers on top of the fork sliders are damaged and allowing foreign matter to get past. Check that the dust covers are properly secured and replace them if they are cracked or otherwise damaged.
5. Support the front wheel off the ground. Remove the filler bolt from the top of the fork leg. On late models, the rubber cap must be removed first.
6. Add the correct quantity of oil to each fork leg. This amounts to 165 cc (5.6 oz.) for KZ650-B models, and 160 cc (5.4 oz.) for later models. These amounts apply to routine oil changes. If the forks are being refilled after rebuilding, add an additional 20–30 cc (0.68–1.0 oz.) per fork leg.
7. Inspect the filler bolt o-rings for damage and replace them if necessary. Install the bolts and tighten them securely. Install the cap, if fitted.
8. After several miles of operation, check the area around the fork slider seals for leaks or seepage. Even a minimal amount will require replacement of the seals. A coating of grime building up in this area over a period of time is also indicative of ineffective seals.

Front Forks (Air-Type)

CAUTION: *Air fork adjustments must be co-ordinated with rear shock settings according to factory specifications. Refer to the "Chassis" section for proper settings.*

1. SAE 10W oil is recommended for air forks.
2. Place the motorcycle on the center stand.
3. Depressurize each fork leg by means of the air valve at the top of the fork legs.
4. Remove the handlebars.
5. Remove the fork drain screw at the lower end of the slider. Pump out the fork oil by pumping the forks up and down.
6. Refit the drain screw, securing it with a non-permanent thread-locking compound.
7. Remove the filler cap and pull out the fork spring.
8. Add the proper amount of oil to each fork leg.

9. Fork capacities are as follows:

KZ 650D/F	225 cc
KZ 650H	270 cc
KZ 750E	230 cc
KZ 750H	260 cc

NOTE: *If the fork is being rebuilt, add about 20 cc more per leg.*

10. After refitting the filler caps, adjust front fork air pressure. See "Chassis."

Chasis Lubrication

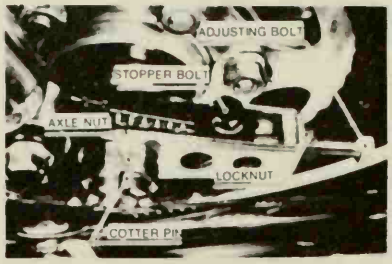
1. The swing arm pivot is fitted with a single grease fitting in the middle of the pivot. A good grade of chassis grease should be applied about every 6,000 miles, or once a year—whichever comes first.

Swing arm grease fitting

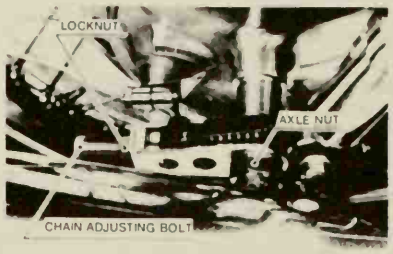
Apply the grease until some of it appears at both ends of the swing arm to ensure thorough lubrication. Wipe off the excess.

2. Every 2 years or 12,000 miles—whichever comes first—the wheel bearings and steering stem bearings should be repacked. Refer to the "Chassis" section for procedures.

3. At 3,000 mile intervals, or more often if the machine is used in wet or inclement weather, various control and chassis pivot points should be lubricated with multi-purpose grease or motor oil. These include the hand lever pivots, side and center stand pivots, and carburetor choke pivots.



SERVICE CHECKS AND ADJUSTMENTS



Drive Chain

1. The chain should have about 20–30 mm (0.75–1.2 in.) of total up-and-down free-play measured in the middle of the lower chain run.

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on the center stand so that the rear wheel is off the ground;

b. The transmission should be placed in neutral;

c. The chain should be clean and well-lubricated;

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably worn sprockets, which should be replaced as soon as possible.

REAR DRUM BRAKE MODELS

1. Back off the rear brake adjusting nut several turns. Remove the securing clip and loosen the brake anchor nut on the brake plate.

2. Loosen the chain adjuster bolt locknuts.

3. Remove the cotter pin and loosen the axle nut several turns.

4. Turn both chain adjuster bolts in by equal amounts until chain tension is approximately correct. Make sure that the notch on each chain adjuster is aligned with the same corresponding swing arm mark on each side.

5. Tighten the chain adjuster bolt locknuts.

6. Spin the rear wheel and then apply the rear brake hard, and hold it on. While holding the brake on, tighten the axle nut. The axle nut should be tightened to 72–101 ft lbs.

7. Recheck chain slack. Readjust if necessary.

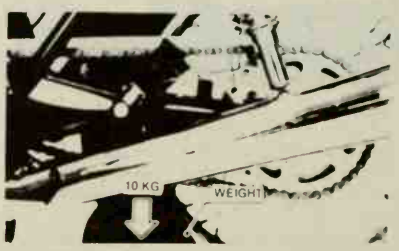
8. Tighten the brake anchor nut and fit the securing clip. Readjust the rear brake.

REAR DISC BRAKE MODELS

1. Remove the cotter pin and loosen the torque link nut. Remove the axle nut cotter pin and loosen the axle nut.

2. Loosen the chain adjuster bolt locknuts.

3. Turn both chain adjuster bolts in by equal amounts until chain tension is approximately correct. Make sure that the notch on each chain adjuster is aligned with the same corresponding swing arm mark on each side.



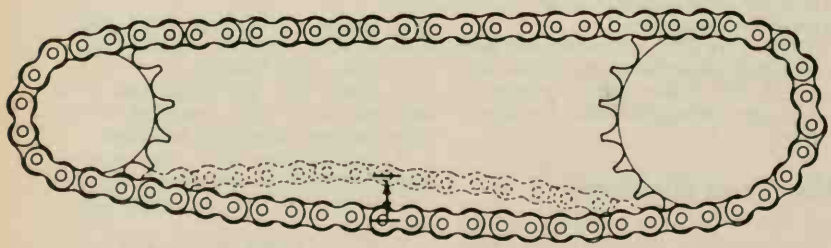
4. Tighten the chain adjuster bolt locknuts. Tighten the axle nut to 72–101 ft lbs. Recheck the chain tension.

5. Tighten the torque link nut to 19–25 ft lbs. Fit the cotter pins to the axle and torque link nuts.

Checking Chain Wear

1. Chain wear is checked by measuring a length of chain and comparing it to the standard specification.

2. With the machine on the center stand, hang a weight of 10 kg (about 15 lbs) from the middle of the lower chain run. Measure the length of twenty chain links. This will be twenty-one pins. The standard length of a new chain is 317.5 mm (12.5 in.). The serviceable limit is 323 mm (12.7 in.). If the measured length between 21 pins exceeds this limit, the chain must be replaced.



Checking chain wear

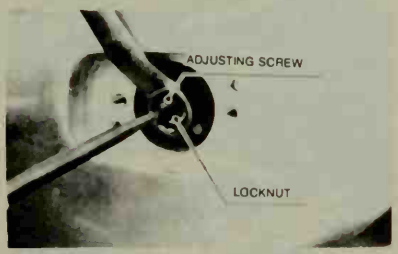
Clutch

1. Clutch cable adjustment must always be maintained at the proper specification. If the cable has insufficient free-play, the clutch will slip and rapidly burn out. If it has too much play, the clutch will not disengage completely, resulting in hard shifting and creeping at stops.

2. Use the cable adjuster at the handlebar or on the cable to maintain the correct amount of cable slack. The clutch hand lever should be able to be moved 2–3 mm (0.08–0.12 in.) measured between the lever and the lever holder before the clutch begins to disengage.

Drive chain slack is measured in the middle of the lower chain run

The clutch lever should have 2–3 mm of play before the clutch begins to disengage



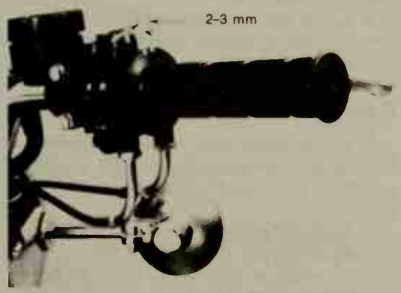
If clutch operation is not satisfactory after making this adjustment, proceed as follows:

3. Loosen the locknut on the adjuster midway down the cable and screw the adjuster in as far as possible, providing the cable with plenty of slack.

4. Loosen the locknut on the cable adjuster at the hand lever and turn the adjuster so that there is a gap of 5–6 mm (0.20–0.24 in.) between the adjuster and the locknut.

5. Remove the clutch adjuster cover. Loosen the adjuster locknut and back the adjusting screw off two or three turns.

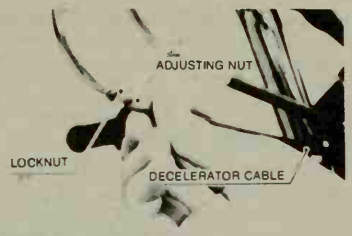
6. Turn the adjusting screw in until it becomes hard to turn. From this point, back the screw off ½ turn. Hold the screw in this position and tighten the locknut.



Adjusting the clutch

7. Take up all of the cable slack with the cable adjuster mid-way on the cable. Tighten the cable adjuster locknut.

8. Make sure that the cable sheath is properly fitted into its hole in the engine sprocket cover.



9. Use the cable adjuster at the hand lever to adjust the cable so that the hand lever can be moved 2–3 (0.08–0.12 in.) measured between the lever and the lever holder before the clutch begins to disengage.

The twist-grip should have 2–3 mm of rotation before the slides begin to open

When the throttle is pushed completely closed, there should be no cleerance between the cable bracket and the stopper

Adjusting the throttle cables

Throttle Cables

1. When the cables are properly adjusted, it should be possible to rotate the twist-grip 2–3 mm (0.08–0.12 in.) before the slides begin to open. Further, when the throttle is pushed completely closed, there should ge no clearance between the cable bracket and the stopper.

If either of these checks indicates that adjustment is necessary, proceed as follows:

2. Loosen the locknuts on the cable adjusters at the twist-grip and screw the adjusters in as far as possible, giving the cables plenty of slack.

3. Turn the decelerator cable adjuster out until there is no clearance between the cable bracket and the stopper when the twist-grip is pushed to the completely closed position. Tighten the locknut.

4. Turn the accelerator cable adjuster out until the twist-grip can be rotated 2–3 (0.08–0.12 in.) before the slides begin to lift. Tighten the locknut.

NOTE: *If the cables cannot be properly adjusted with the adjusters at the twist-grip, use those at the carburetors.*

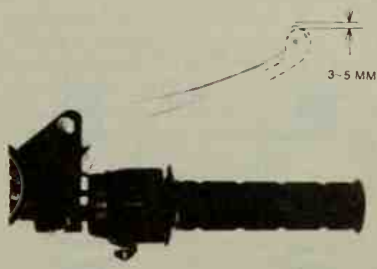
5. To check that the cables have sufficient slack, start the engine and allow it to idle while turning the handlebars slowly from lock-to-lock. Idle speed must not be affected. If it is, it is probable that the cables are too tightly adjusted, are incorrectly routed, or are binding somewhere along their route.

Brakes

FRONT DISC

Disc brakes need no attention other than a periodic check of fluid level and pad wear.

1. After removing the reservoir cap and rubber diaphragm, check to see if the fluid is up to the level mark on the inside of the master cylinder. If the level is below the level mark, add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and the cap, and tighten securely.



NOTE: *The fluid level will drop slightly as the pads wear.*

2. Check the brake pad wear, and replace the pads in a set if either one is worn to the red limit line.

Refer to "Chassis," for brake system service procedures.

3. If the brake lever feels spongy, bleed the system. This procedure can also be found in "Chassis."

4. There should be 3–5 mm (0.12–0.20 in.) of front brake lever travel. An adjusting bolt is fitted to the underside of the master cylinder for this purpose. If adjustment is necessary, bend up the tab on the adjusting bolt locknut, loosen the locknut, and turn the adjusting bolt

The brake lever should have 3–5 mm of movement

very slightly in one direction or the other so that the hand lever has the correct amount of travel. Hold the bolt in this position, and tighten the locknut to 13–16.5 ft lbs. Bend down the tab over one of the flats of the nut.

This adjustment will usually not have to be reset once lever travel is correct. If the lever travel becomes excessive and the brake pads are satisfactory, suspect air in the brake lines. In this event, the system will have to be bled.

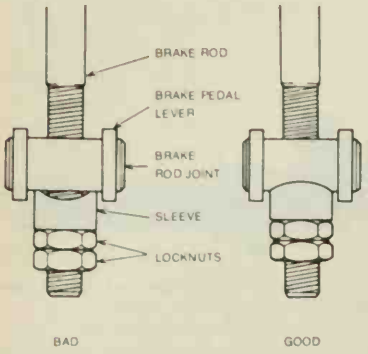
REAR DISC

1. The transparent master cylinder allows inspection of the fluid level without removing the master cylinder cap. If the fluid level is below the level mark, remove the cap and diaphragm and add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and cap and tighten it securely.

2. Check the brake pads for wear and replace them as a set if they are worn to the red limit line.

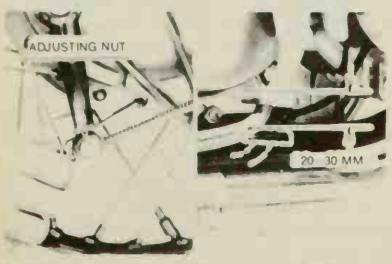
3. The rear brake pedal should have 8–10 mm (0.32–0.40 in.) of freeplay. If adjustment is necessary, loosen the brake pushrod locknuts and turn the pushrod until freeplay is corrected. Tighten the locknuts.

NOTE: *Before tightening the locknuts, be sure the sleeve is properly seated on the brake rod joint, as illustrated.*



The rear disc brake pedal should have 8–10 mm of free play

4. Brake pedal height should be 20–30 mm (0.8–1.2 in.) below the upper surface of the footpeg. If pedal height is too high, loosen the brake pushrod locknuts, slide down the dust cover, and shorten the pushrod, providing plenty of play in the pedal. Then adjust pedal position with the adjusting bolt.



If pedal height is too low, loosen the adjusting bolt locknut and turn the bolt to yield the proper height. Tighten the locknut. Check brake pedal travel, and adjust if necessary.

REAR DRUM

1. The rear brake pedal should have 20–30 mm (0.8–1.2 in.) of freeplay before the shoes contact the drum. Use the adjusting nut on

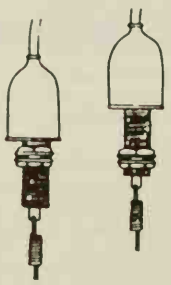
Be sure that the sleeve is properly seated on the brake rod joint

Adjust the rear drum brake to give 20–30 mm of pedal play before the linings contact the drum

the back of the brake rod to make this adjustment.

The adjustment should be made with the machine on its wheels and the weight of a rider on the seat. The pedal should be depressed lightly by hand to find the freeplay.

2. After making this adjustment, check that the brakes do not drag after application. Check the operation of the rear brake light and adjust if necessary.



3. At rest, the brake pedal should be positioned 20–30 mm (0.8–1.2 in.) below the upper surface of the footpeg. If adjustment is necessary, back off the brake adjusting nut and use the pedal stopper bolt to change the pedal height. Readjust the brake after this correction is made.

4. A pointer is provided indicating brake shoe condition by means of a "usable range" when the brake is fully applied. When the pointer leaves this range, the brake shoes must be replaced.

5. When the brakes are fully applied, the angle formed by the brake rod and the brake lever should be approximately 90°. If the angle exceeds this amount, brake effectiveness will be greatly reduced. If necessary, remove the brake lever and move it one or more splines on the brake cam to restore the angle. Do not disturb the brake wear indicator when this is done.

Brake Light Switches

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch and adjuster nut are mounted on a slotted bracket. The rear switch is adjusted by holding the switch and turning the adjuster nut to effect adjustment. Moving the switch upon the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to effect adjustment as the wires will become twisted and may break. Generally, the brake light should come on after the pedal has moved 15 mm (0.6 in.).

Brake light switch adjustments

The front switch is activated by the pressure of the brake fluid in the brake line. This switch is not adjustable; if defective, it must be replaced.

Headlight Adjustment

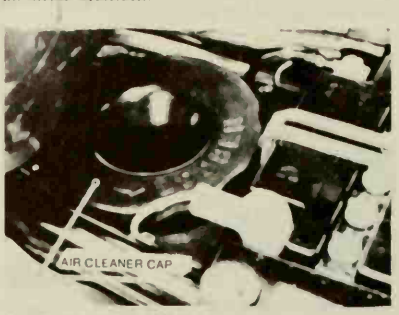
1. Set the machine about 25 feet away from the perpendicular to a wall, preferably of a color which reflects light well.

The machine should be off the stand, and with a rider putting his weight on the machine as in operation.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

3. Vertical adjustment is made by loosening the two headlight shell mounting bolts slightly and pivoting the shell up or down.

4. Lateral adjustment is accomplished by means of the screw on the right side of the headlight. Turning the screw clockwise will move the beam to the left, turning it counterclockwise will move it to the right.



FUEL SYSTEM

Fuel system maintenance involves cleaning or replacing the air filter, cleaning the fuel petcock sediment cup and filter screens, and cleaning the carburetor float bowls.

The normal service interval is 3,000 miles. The air filter element should be replaced every 6,000 miles.

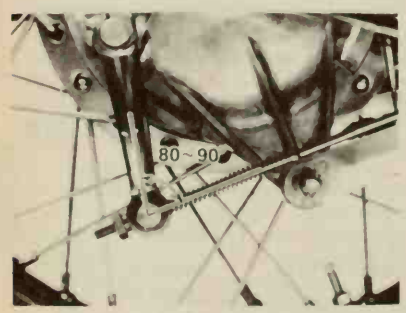
Air Filter

1. Open the seat. Unscrew and remove the air cleaner cap. It will be necessary to lift the end of the tank to clear the cap. Remove the air filter element.

Air cleaner cap location

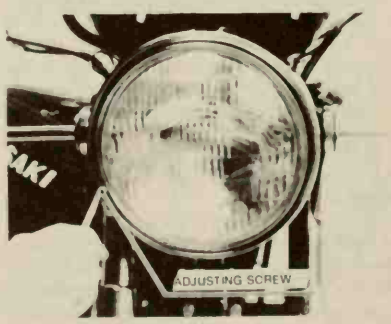
2. Clean the element with a high flash-point solvent. Do not use a solvent such as kerosene or anything else which will leave an oily residue on the element. After cleaning, dry the element by applying compressed air to the inside area.

3. After about five such cleanings, or every 6,000 miles, the filter element should be replaced with a new one.



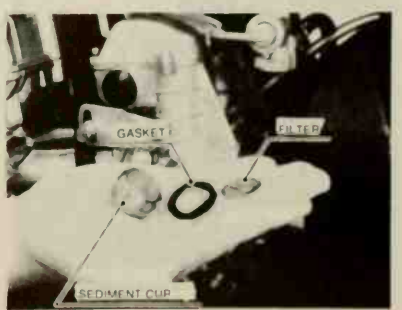
4. Check that the sponge gaskets are properly secured to the element. If they are not, stick them on with an adhesive. If the gaskets or the element itself is damaged or holed, it should be replaced.

5. Installation is the reverse of removal. When installing the air cleaner cap, screw it on until a click is heard.



Petcock

1. The petcock has a sediment cup and a filter screen just above it, and also has filter screens on the intake pipes inside the gas tank.



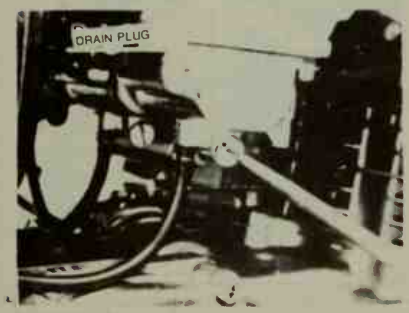
2. Shut the fuel off. Unscrew and remove the sediment cup. Take out the filter screen. Clean any dirt or debris from the cup. Brush the surface of the filter screen to remove any trapped foreign matter. Check the condition of the gasket and replace it if it is crushed or knicked.

The angle between the brake lever and rod should be 80–90° when the brake is fully applied

Headlight lateral adjustment screw

Petcock sediment cup components

3. If water was present in the cup, place a container beneath the petcock and turn on the gas in the "reserve" position. Drain off the gasoline until there is no water left in the fuel.



4. Refit the filter screen, the gasket, and the cup. Turn on the gas and check for leaks before operating the motorcycle.

5. At longer intervals, the filter screens inside the tank should be attended to. Disconnect the fuel line from the petcock. Remove the gas tank and drain off the gasoline. Remove the two screws which secure the petcock to the tank. Carefully clean the intake pipe filters. Check the petcock sealing o-ring for damage and replace it if necessary.

Carburetors

1. Although thorough cleaning of the carburetors necessitates their removal from the motorcycles, water and foreign matter can be removed from the float bowls simply by removing the drain plug and allowing the contents to drain into a suitable container. Be sure the petcock is off before removing any of the drain plugs.

2. It is also possible to clean the jets by removing the float bowls. Refer to the "Fuel System" section for procedures.

Removing the float bowl drain plug

Recommended Lubricants

Engine
- SAE 10W-40, service rating "SE"
- SAE 10W-50, service rating "SE"
- SAE 20W-50, service rating "SE"

Front forks
- KZ650-B: SAE 10W
- KZ650-C/D: SAE 15W
- Other models: SAE 10W

Disc brakes
- DOT 3 standard hydraulic disc brake fluid

Control cables
- Light motor oil
- Graphite-based lubricant
- Molybdenum-disulphide-based lubricant

Tach, speedometer cables; throttle twist-grip
- Light duty grease

Wheel and steering stem bearings
- Waterproof, medium-weight bearing grease

Grease fitting
- Waterproof, medium-weight chassis grease

Drive chain
- Lubricant developed specifically for motorcycle drive chains

Periodic Maintenance Intervals①

Before each ride
- Safety items
- Operation of lights
- Chain adjustment
- Control cable adjustment
- Brake operation

Periodic Maintenance Intervals①

Weekly
- Engine oil level
- Tire pressure (check when cold)
- Battery electrolyte level

Every 200 miles
- Lubricate chain

Every 500 miles
- Check drive chain slack
- Check tightness of critical fasteners

Every 1800 miles/3 months
- Change engine oil

Every 3000 miles/6 months
- Check brakes and brake fluid level
- Check clutch
- Adjust carburetors
- Check cable free-play
- Check spokes and rim run-out
- Clean fuel system
- Clean and gap spark plugs
- Check point gap and ignition timing
- Adjust cam chain
- Check valve clearance
- Check drive chain wear
- Clean air filter element
- Perform general lubrication

Every 3600 miles/6 months
- Change oil filter element

Every 6000 miles/12 months
- Check steering stem bearing play
- Check brake pads/linings for wear
- Lubricate timing advance mechanism
- Replace air cleaner element
- Change disc brake fluid
- Lubricate swing arm
- Change front fork oil

Every 12000 miles/24 months
- Repack wheel bearings and steering stem bearings
- Repack speedometer gear housing
- Grease drum brake cam

① Based on normal usage after initial service and break-in are completed

Maintenance Data

Fuel capacity	16.8 1/4.4 gal.
Oil capacity	
When changing oil only	3.0 1/3.2 qts.
When changing oil and filter	3.5 1/3.7 qts.
Front forks (each leg)	
KZ650-B	165 cc/5.6 oz.①
KZ650-C/D	160 cc/5.4 oz.①
KZ650-D/F	225 cc/7.6 oz.①
KZ650-H	270 cc/9.1 oz.①
KZ750-E	230 cc/7.8 oz.①
KZ750-H	260 cc/8.8 oz.①
Tire pressure	
Front	28 psi
Rear (solo)	32 psi
Rear (two-up or high-speed)	36 psi
Battery	
Make/Model	Yusa/YB10L
Voltage/Output	12v/10 ah
Continuous charging rate	1.0 amp

① When refilling forks after rebuilding, add an additional 20-30 cc (0.68–1.0 oz.) per leg to the given quantities

TUNE-UP

Common tune-up procedures are explained in detail in the "General Information" section.

COMPRESSION TEST

1. A compression check should be made before each tune-up since this will provide a general idea of engine condition.

2. It is necessary to have a gauge with a flexible hose and the proper screw-in adapter (plug holes are 14 mm).

3. The engine should be at operating temperature when checking compression.

4. Remove all of the spark plugs and fit the gauge to one of the plug holes.

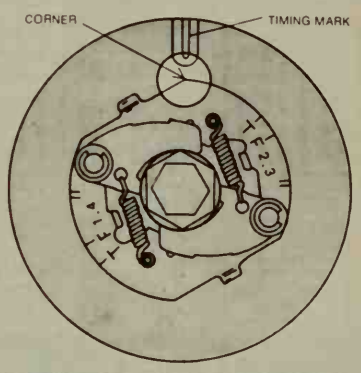
5. Close the choke and hold the throttle wide open while spinning the engine with the starter motor. Note the compression reading and repeat the test with the remaining cylinders.

6. Compression may vary according to gauge tolerance and several other factors. However, it should normally be between 156 and 185 psi. All cylinders must be within 15 psi of this range and of each other.

CAM CHAIN ADJUSTMENT

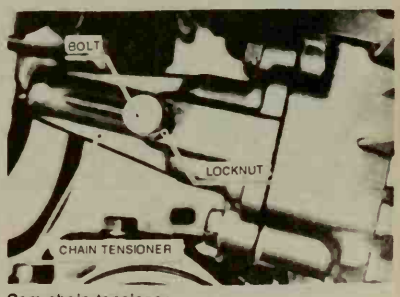
NOTE: *Late models have automatic cam chain adjustment. For earlier models with a manually adjusted chain, the procedure is as follows.*

1. Remove the contact breaker cover.



2. With a 17 mm wrench, turn the crankshaft in the normal direction of rotation (clockwise) about two turns. Then position the corner of the timing advance mechanism near the Nos. 2 and 3 timing marks so that it aligns with the stationary timing mark.

NOTE: *Do not turn the crankshaft backwards to achieve this alignment. If you go past the point of aligment, continue turning the crankshaft in the normal direction of rotation.*



3. Loosen the cam chain tensioner locknut and back the bolt off a couple of turns. Cam chain tension will be set automatically.

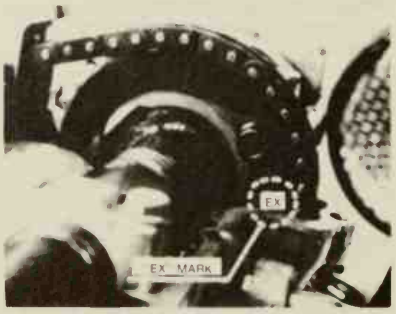
4. Tighten the tensioner bolt to 61–78 in. lbs. Tighten the locknut.

5. Refit the contact breaker cover.

Crankshaft position for cam chain adjustment

Cam chain tensioner

6. If adjustment does not remedy excessive cam chain noise, it is probable that the cam chain or the chain guides are worn to the point of replacement.



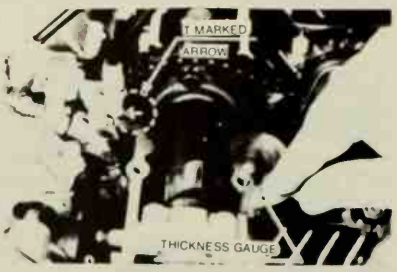
VALVE ADJUSTMENT

Checking Clearance

NOTE. *Valve clearance must be checked when the engine is COLD.*

1. Remove the gas tank. Remove the ignition coils.
2. Remove the cylinder head cover bolts and take off the cover.
3. Remove the contact breaker cover.
4. Using a 17 mm wrench, turn the crankshaft over until the line marked "Ex" on the exhaust cam sprocket is pointing forward and is aligned with the cylinder head surface. With the engine in this position, clearance can be checked at the exhaust valves of cylinders Nos. 1 and 3.
5. With a feeler gauge of the proper thickness, measure the clearance at the exhaust valves of cylinders Nos. 1 and 3. (Cylinders are numbered consecutively from left to right.)

The correct clearance is 0.08–0.18 mm (0.003–0.007 in.). A feeler gauge of the proper thickness should be a light slip fit between the cam and the valve lifter. If the measured clearance is not within this range, the clearance must be adjusted by substituting shims of the proper thickness. Refer to "Adjusting Clearance," below.

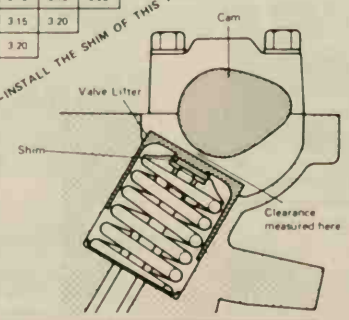


Cam sprocket position to check the valve clearance at the exhaust valves for cylinders Nos. 1 and 3

Check valve clearance between the cam lobe and the tappet

6. Turn the engine over until the line marked "Ex" for the exhaust cam sprocket is pointing towards the rear of the engine and is aligned with the cylinder head surface. In this position, the exhaust valves for the remaining two cylinders (Nos. 2 and 4) can be checked.
7. To check the clearance of the intake valves, turn the engine over until the arrow marked "T" on the intake cam sprocket is pointing towards the rear of the engine and is aligned with the cylinder head surface. Check the clearance of the intake valves for cylinders Nos. 1 and 3.

Cam sprocket position for checking valve clearance at the intake valves for cylinders Nos. 1 and 3



As for the exhaust valves, proper clearance is 0.08–0.18 mm (0.003–0.007 in.).

8. Turn the engine over again until the arrow marked "T" is pointing towards the front of the engine and aligned with the cylinder head surface. Check the clearance at the intake valves for cylinders Nos. 2 and 4.

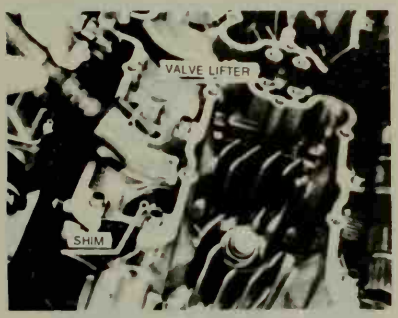
1. Measure the clearance (when cold).
2. Check present shim size.
3. Match clearance in vertical column with present shim size in horizontal column.
4. The shim specified where the lines intersect is the one that will give you the proper clearance.



NOTE: If there is no clearance, select a shim which is several sizes smaller and then measure the clearance.

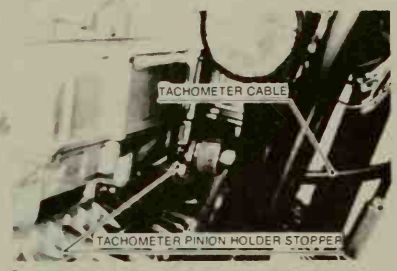
CAUTION
1. Do not put shim stock under the shim. This may cause the shim to pop out at high rpm causing extensive engine damage.
2. Do not grind the shim. This may cause it to fracture, causing extensive engine damage.
3. Check the valve clearance with the proper method in the text. Checking the clearance at any other cam position may result in improper valve clearance.

If the measured clearance is not within the proper range, the valves must be adjusted as outlined under "Adjusting Clearance," below.

Adjusting Clearance

1. Valve clearance is adjusted by removing the fitted shim from beneath the valve lifter and fitting another thicker or thinner one.
2. First it is necessary to find the true valve clearance. If the clearance is not within the specified range, use feeler gauges between the cam and valve lifter until the true clearance is determined. The feeler gauge blade should be a light slip fit.
3. Remove the camshaft. Remove the valve lifter. This procedure is outlined below.
4. Remove the installed shim and check the size marked on it. Refer to the "Valve Adjustment Chart," find the measured valve clearance and the present shim size. Where the two lines intersect, find the correct new shim to install. Shims are available in sizes from 2.0–3.2 mm in increments of 0.05 mm.

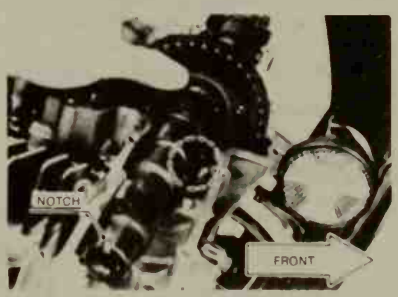
Valve lifter (tappet) and adjusting shim



5. Before adjusting the valve clearance, note the following points:
   a. never put shim stock beneath the shim; it may pop out.
   b. never grind a shim; this may cause it to fracture.
   c. if the smallest available shim will not yield the proper clearance, the valve seat is probably worn. In this case, inspect the valve seat and stem installed height. Refer to the "Engine and Transmission" section.
6. After fitting a shim of the correct size as derived from the "Valve Adjustment Chart," refit the camshaft and recheck the clearance in the normal manner.

CAMSHAFT REMOVAL AND INSTALLATION

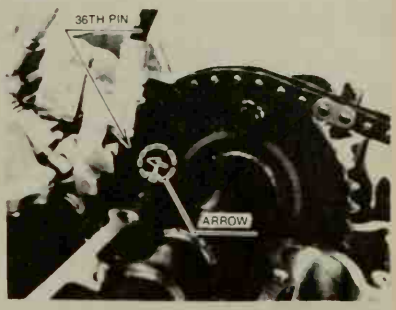
CAUTION: *On late models, the cam chain and the valve timing marks of the cam sprockets was changed. The chain on early models was a single-row type; late models have a hy-vo chain. Early cam sprockets are marked with arrows and "T" letters; later models have "IN" and "Z6EX" marks on 650s and "Z7EX" on 750s for valve timing.*



To remove the camshaft(s) for valve adjustment, proceed as follows:

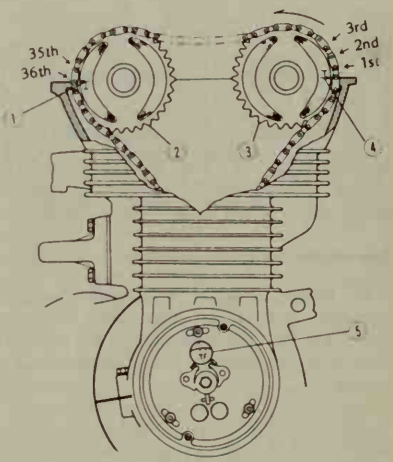
1. Turn the crankshaft over until the "T" mark for cylinders Nos. 1 and 4 is aligned with the stationary timing mark. This puts those cylinders at top dead center.
2. Remove the screw and remove the tachometer pinion holder stopper. Pull the

Remove the tachometer pinion holder stopper

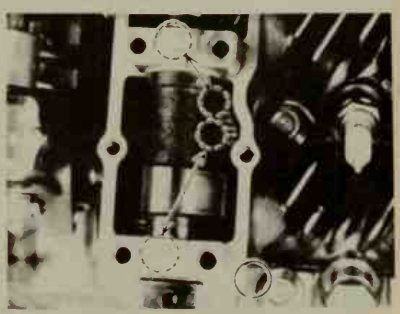


tachometer pinion holder and pinion with the tach cable off the cylinder head.
3. Remove the cam chain tensioner.
4. Remove the cam chain upper chain guide sprocket (4 allen bolts).
5. Remove the camshaft cap bolts and remove the caps.
6. Remove the camshafts. Loop a length of wire or the like around the cam chain so that it won't fall into the crankcases.
7. To install the camshafts, first make sure that the crankshaft is still positioned so that the "T" mark for cylinders Nos. 1 and 4 is aligned with the stationary timing mark.
8. Pull the camshaft chain taut to remove any kinks in it. Install the exhaust camshaft noting that the notched end of the camshaft goes to the right side of the engine. Position the exhaust cam so that the arrow marked "T" on the cam sprocket is pointing towards the front of the engine and is aligned with the cylinder head surface. Keeping the cam in this position, pull the cam chain taut and loop it over the cam sprocket. On late models the exhaust cam is installed so that the "Z6EX" or "Z7EX" mark is aligned with the cylinder head surface.
9. Install the intake camshaft, positioning it so that the arrow marked "T" on the cam sprocket is pointing towards the rear of the engine and is aligned with the cylinder head surface. On late models, the mark on the in-

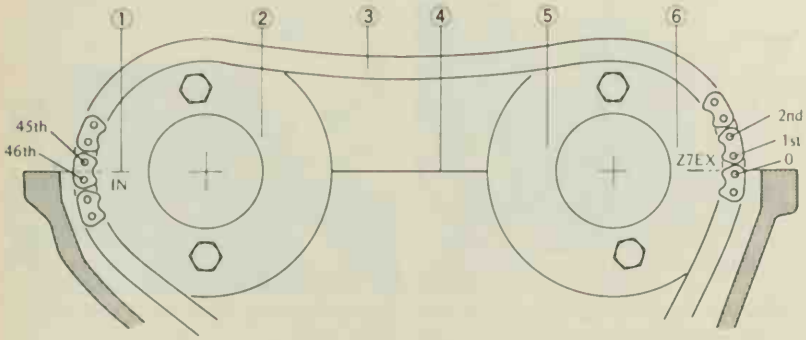
The notch on the end of the cam must be positioned on the right side



Align the arrow marked "T" with the cylinder head surface. On late models the mark "Z6EX" is to be aligned



Correct positioning of the intake cam sprocket (early models)



take cam sprocket which should be aligned with the cylinder head surface is indicated by the letters "IN."
10. Find the cam chain pin pointed at by the exhaust cam "T" arrow or "Z6EX"/"Z7EX" index mark. With this pin as "zero," count off thirty-six (36) pins on early models with the single-row chain, or forty-five (45) pins on late models with the hy-vo chain. Be sure that the index mark on the intake cam sprocket points towards this 36th pin or between pins 45 and 46 on hy-vo chain engines. If it does not, the camshafts are not properly aligned, and engine damage will be the result if the engine is rotated.

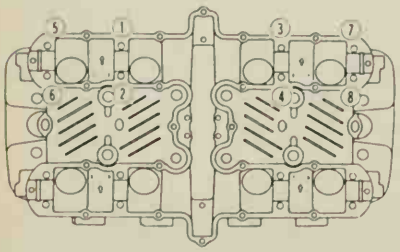
3. Exhaust Camshaft Sprocket
4. T-marked Arrow
5. #1, 4 TDC Mark

Correct valve timing (early models)

When installing the cam caps, match the number on the caps with the number on the head. Install the caps so that the arrows point towards the exhaust side of the engine



1. "IN" mark
2. Intake cam sprocket
3. Cam chain
4. Cylinder head mating surface
5. Exhaust cam sprocket
6. "Z6EX" or "Z7EX" mark

Correct valve timing for late models

11. Before installing the camshaft caps, note that the caps are identified by a number. Match the number on the cap with that on the cylinder head. Install the caps so that the arrows on the caps point towards the exhaust side of the engine.

12. Partially tighten the left-inside cam caps first to seat the camshaft. Then tighten the cap bolts in the order shown in the illustration until the proper torque of 7.9–10.8 ft lbs is reached.

Cam cap bolt tightening sequence

13. Install the upper chain guide sprocket assembly and tighten the allen bolts to 6.5–7.9 ft lbs. The bolts should be secured with a non-permanent thread-locking compound.

14. Install the cam chain tensioner assembly. Note that the red side of the assembly gasket must face the cylinder. Apply liquid gasket to both sides of the assembly bolt washers. Tighten the bolts evenly to 5.1–6.5 ft lbs.

15. Recheck the valve timing before rotating the engine. Turn the engine over slowly at first. If any resistance is felt, stop at once and determine the cause. Improper valve timing may cause the valves to hit the pistons or each other. Turn the engine through several complete revolutions and realign the "T" mark for cylinders Nos. 1 and 4. Check that the cam sprocket marks are still aligned as before.

16. Apply a small amount of high temperature grease to the tachometer pinion shaft, and insert the pinion and pinion holder into the cylinder head. Secure the pinion holder with the holder stopper and screw.

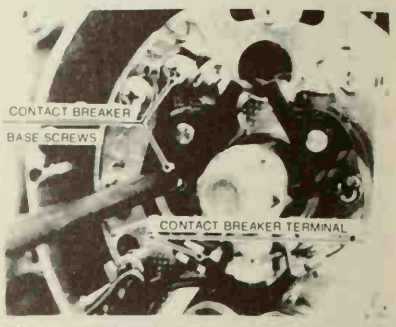
17. Lubricate all of the top end components before refitting the cylinder head cover.

CONTACT BREAKER POINTS

Location

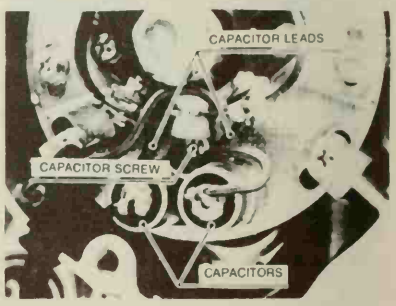
The points and condensers are located on the right end of the crankshaft beneath the points cover. The timing advance mechanism is fitted onto the crankshaft behind the breaker point base plate.

Replacement



1. Points sets are available complete with condensers already mounted on the breaker plate. Disconnect the primary wires at the connectors. Carefully pull the wires through, noting the proper routing. Remove the three screws which secure the breaker plate. When the new plate is fitted, position it so that the securing screws are approximately centered in their slots, and adjust the point gaps and the ignition timing.

2. If the points are purchased separately, disconnect the primary wire at each point set, remove the securing screws, and remove the old points. When installing new points, note that the proper installation of the insulating washers at the primary terminal is critical. If improperly installed, no spark will occur. There is a small insulating washer which fits around the terminal bolt and two insulating washers, one immediately on either side of the terminal bracket. All connectors (condenser, primary wire, points spring) are made on the outer sides of these washers (i.e., no connector must touch the bracket, which is a ground).

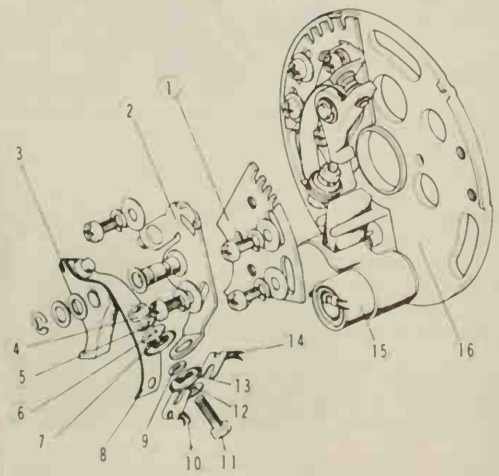


3. New points may have a protective coating on the contact surfaces to prevent oxidation. Clean off these surfaces with a non-oily solvent before attempting to start the machine.

4. If the motorcycle will not start immediately after installation of new points, check that the primary wire connections are tight, that the insulating washers at the primary terminal are properly installed, and that the contact surfaces are thoroughly cleaned.

5. Condensers are easily replaced after disconnecting the lead at the primary terminal, and removing the securing screw.

Removing the contact breakers



Capacitor securing screw

Gapping

FEELER GAUGE METHOD

Periodic gapping is necessary to compensate for erosion of the contact surfaces due to electrical arcing and for wear of the fiber heel. As the heel wears, the points will open later relative to the rotation of the crankshaft, thus retarding the time slightly.

1. Contact breaker adjusting plate
2. Contact breaker base plate
3. Contact breaker
4. Nut
5. Lockwasher
6. Flat washer
7. Large insulator
8. Spring
9. Small insulator
10. Contact breaker lead
11. Bolt
12. Flat washer
13. Large insulator
14. Capacitor lead
15. Capacitor
16. Contact breaker plate

Contact breaker assembly

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the points cover.
2. Turn the engine over until one of the two sets of points is fully open.
3. With the proper feeler gauge blade, check the gap. The proper specification is 0.3–0.4 mm (0.012–0.016 in.), and the blade should be a slip fit between the points if the gap is correct.

Checking the point gap. Loosen the screws indicated by arrows to adjust the gap

4. If adjustment is necessary, loosen the screws which secure the point set to its plate, and use a small screwdriver at the pry point provided to adjust the gap.

CAUTION: *Loosen the screws just enough to allow the points to be moved. If loosened too much, the points will snap shut instead of holding the gap.*

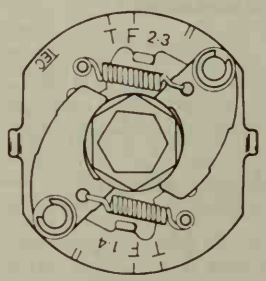
5. Tighten the screws and recheck the gap. It may change slightly when the screw is tightened.
6. Repeat the procedure with the remaining points set. Try to adjust both sets so that the feeler gauge blade has the same "feel" in both sets. This will help to ensure accurate timing.
7. If it is not possible to gap the points correctly, the fiber heel is evidently worn, the points should then be replaced.

DWELL METER METHOD

Point gap can also be adjusted with the aid of a dwell meter if one is available. "Dwell" is the amount of time the points are closed relative to crankshaft revolution and is expressed in degrees.

The adjustment is made with the engine idling, the positive meter connections lead to the primary wire terminal, and negative lead to the engine (ground).

With the meter set to the "8 cylinder" range, the proper dwell specification will be 23.75°; if set to the "4 cylinder" range, it will be 47.5°.



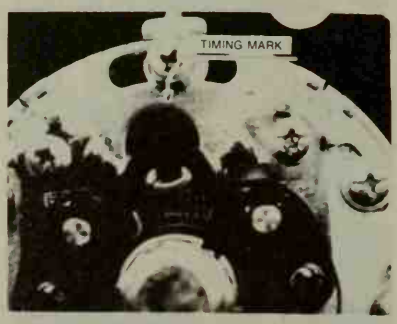
Increasing the point gap will decrease the dwell reading, and vice-versa.

Lubrication

1. It is necessary to occasionally lubricate the cam follower fiber heel and the pivot point of the contact breaker. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.
2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.
3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.
4. The lubricating wick should be adjusted so that it just contacts the breaker cam.

IGNITION TIMING (BREAKER POINT IGNITION)

The timing advance mechanism behind the breaker plate is fitted with marks which indicate piston position when they are aligned with the stationary timing mark (visible through the inspection hole in the breaker plate). There are two sets of marks, identified 1.4 and 2.3 to indicate which cylinders they represent.



Timing advance mechanism ignition timing marks

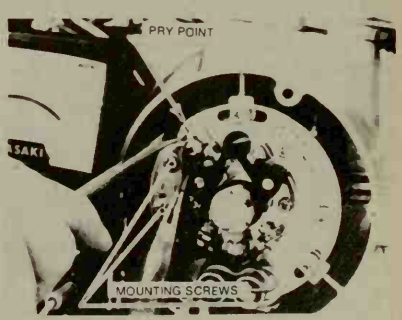
The timing marks on the advance mechanism are interpreted as follows: "T" indicates top dead center, "F" is the fixed advanced firing point, which is when the plug fires before the automatic timing advancer comes into play and is about 10° BTDC. An additional pair of

Observing the breaker plate, note that the points set on the left are marked "1.4." They control the timing for those two cylinders. The righthand points, marked "2.3," control the timing for the remaining cylinders.

Dynamic Timing

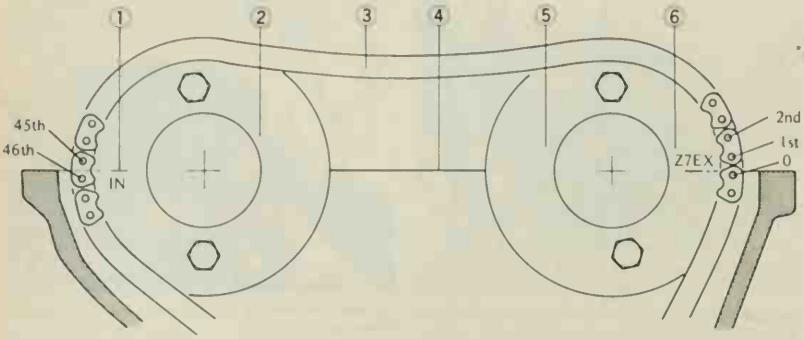
1. Clean and gap both sets of points as described previously.
2. Hook up the strobe light according to the directions of the light's manufacturer to pick up the impulses from the No. 1 (left outside) cylinder.
3. Start the engine and adjust the idle, if necessary, to the recommended idle speed.

Stationary timing mark



4. Aim the light at the timing marks visible through the inspection hole in the points base plate. At idle, the "F" mark should align with the timing index mark.
5. To check ignition timing at full advance, increase the engine speed until the motor is turning 3,000–3,400 rpm. At this point, the timing index mark should be between the two full advance marks scribed into the timing advance mechanism.
6. If adjustment is necessary, loosen the two screws which secure the 1.4 points to the breaker plate and rotate the points using a screwdriver at the pry point provided until timing is correct. Loosen the two screws just enough to allow the points to be moved.

If it is not possible to achieve correct timing by moving the points alone, center the securing screws at the median adjustment position. Then loosen the three screws which secure the breaker plate itself. Rotate the plate until the timing is corrected.

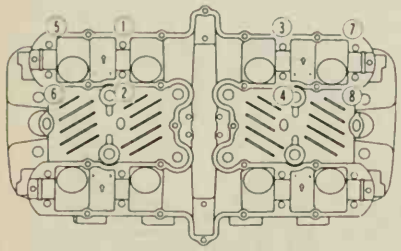


7. Repeat the procedure, this time having the strobe light pick up cylinder No. 2. If adjustment is necessary, loosen the two screws which secure points set 2.3 to its plate, and use a small screwdriver at the pry point provided to move the set so that proper mark alignment is achieved. Tighten the screws.
8. If it is not possible to achieve full advance alignment without moving the breaker base plate or points set 2.3 all the way to the end of their range of allowable travel, it is possible that the points are either incorrectly gapped, or that they are worn to the point where they must be replaced.
9. If other troubles are encountered, see "Troubleshooting" below.

Static Timing

1. Connect one of the test light or tester leads to the primary wire terminal for the points set "1.4." Ground the other lead to the engine.
2. If the test device is not self-powered, turn the ignition switch *on* and be sure the kill switch is in the "on" position as well.
3. Turn the engine over in the normal direction of rotation until the "F" mark for cylinders 1 and 4 align with the timing index mark. The test instrument should react at the instant these marks align, indicating that the points have opened. If they do not, loosen the two screws and rotate the points so that the points are just opening when the marks align. If it is not possible to do so and the points have been moved to the end of their possible adjustment range, set them at the median position and tighten the screws. Loosen the three breaker base plate screws and rotate the plate so that correct timing is achieved.
4. Repeat the procedure with points set

Adjusting the timing



1. "IN" mark
2. Intake cam sprocket
3. Cam chain
4. Cylinder head mating surface
5. Exhaust cam sprocket
6. "Z6EX" or "Z7EX" mark

Correct valve timing for late models

11. Before installing the camshaft caps, note that the caps are identified by a number. Match the number on the cap with that on the cylinder head. Install the caps so that the arrows on the caps point towards the exhaust side of the engine.

12. Partially tighten the left-inside cam caps first to seat the camshaft. Then tighten the cap bolts in the order shown in the illustration until the proper torque of 7.9–10.8 ft lbs is reached.

Cam cap bolt tightening sequence

13. Install the upper chain guide sprocket assembly and tighten the allen bolts to 6.5–7.9 ft lbs. The bolts should be secured with a non-permanent thread-locking compound.

14. Install the cam chain tensioner assembly. Note that the red side of the assembly gasket must face the cylinder. Apply liquid gasket to both sides of the assembly bolt washers. Tighten the bolts evenly to 5.1–6.5 ft lbs.

15. Recheck the valve timing before rotating the engine. Turn the engine over slowly at first. If any resistance is felt, stop at once and determine the cause. Improper valve timing may cause the valves to hit the pistons or each other. Turn the engine through several complete revolutions and realign the "T" mark for cylinders Nos. 1 and 4. Check that the cam sprocket marks are still aligned as before.

16. Apply a small amount of high temperature grease to the tachometer pinion shaft, and insert the pinion and pinion holder into the cylinder head. Secure the pinion holder with the holder stopper and screw.

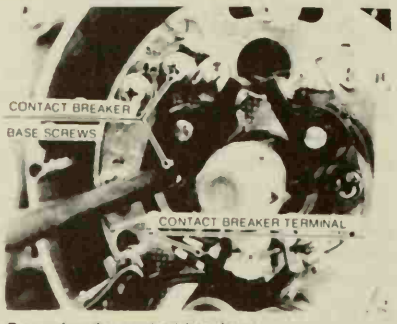
17. Lubricate all of the top end components before refitting the cylinder head cover.

CONTACT BREAKER POINTS

Location

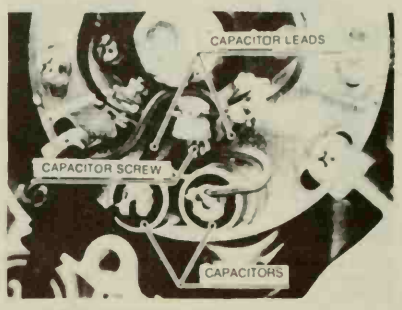
The points and condensers are located on the right end of the crankshaft beneath the points cover. The timing advance mechanism is fitted onto the crankshaft behind the breaker point base plate.

Replacement



1. Points sets are available complete with condensers already mounted on the breaker plate. Disconnect the primary wires at the connectors. Carefully pull the wires through, noting the proper routing. Remove the three screws which secure the breaker plate. When the new plate is fitted, position it so that the securing screws are approximately centered in their slots, and adjust the point gaps and the ignition timing.

2. If the points are purchased separately, disconnect the primary wire at each point set, remove the securing screws, and remove the old points. When installing new points, note that the proper installation of the insulating washers at the primary terminal is critical. If improperly installed, no spark will occur. There is a small insulating washer which fits around the terminal bolt and two insulating washers, one immediately on either side of the terminal bracket. All connectors (condenser, primary wire, points spring) are made on the outer sides of these washers (i.e., no connector must touch the bracket, which is a ground).

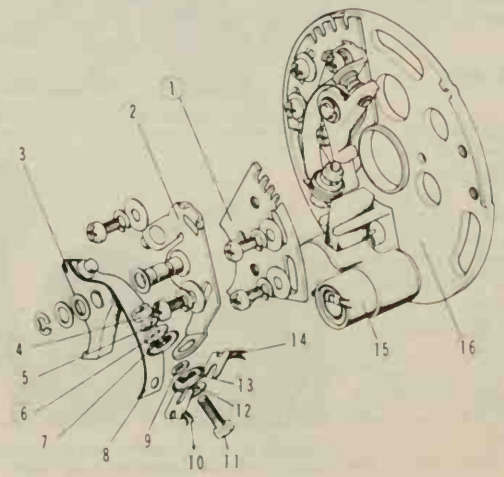


3. New points may have a protective coating on the contact surfaces to prevent oxidation. Clean off these surfaces with a non-oily solvent before attempting to start the machine.

4. If the motorcycle will not start immediately after installation of new points, check that the primary wire connections are tight, that the insulating washers at the primary terminal are properly installed, and that the contact surfaces are thoroughly cleaned.

5. Condensers are easily replaced after disconnecting the lead at the primary terminal, and removing the securing screw.

Removing the contact breakers

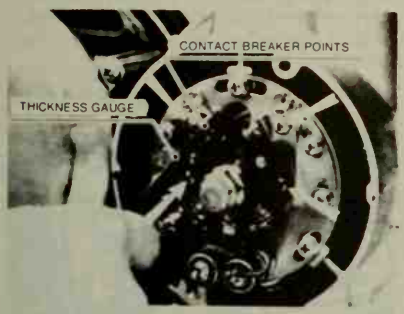


Capacitor securing screw

Gapping

FEELER GAUGE METHOD

Periodic gapping is necessary to compensate for erosion of the contact surfaces due to electrical arcing and for wear of the fiber heel. As the heel wears, the points will open later relative to the rotation of the crankshaft, thus retarding the time slightly.



1. Contact breaker adjusting plate
2. Contact breaker base plate
3. Contact breaker
4. Nut
5. Lockwasher
6. Flat washer
7. Large insulator
8. Spring
9. Small insulator
10. Contact breaker lead
11. Bolt
12. Flat washer
13. Large insulator
14. Capacitor lead
15. Capacitor
16. Contact breaker plate

Contact breaker assembly

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the points cover.
2. Turn the engine over until one of the two sets of points is fully open.
3. With the proper feeler gauge blade, check the gap. The proper specification is 0.3–0.4 mm (0.012–0.016 in.), and the blade should be a slip fit between the points if the gap is correct.

Checking the point gap. Loosen the screws indicated by arrows to adjust the gap

4. If adjustment is necessary, loosen the screws which secure the point set to its plate, and use a small screwdriver at the pry point provided to adjust the gap.

CAUTION: *Loosen the screws just enough to allow the points to be moved. If loosened too much, the points will snap shut instead of holding the gap.*

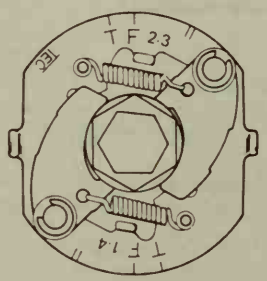
5. Tighten the screws and recheck the gap. It may change slightly when the screw is tightened.
6. Repeat the procedure with the remaining points set. Try to adjust both sets so that the feeler gauge blade has the same "feel" in both sets. This will help to ensure accurate timing.
7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the points should then be replaced.

DWELL METER METHOD

Point gap can also be adjusted with the aid of a dwell meter if one is available. "Dwell" is the amount of time the points are closed relative to crankshaft revolution and is expressed in degrees.

The adjustment is made with the engine idling, the positive meter connections lead to the primary wire terminal, and negative lead to the engine (ground).

With the meter set to the "8 cylinder" range, the proper dwell specification will be 23.75°; if set to the "4 cylinder" range, it will be 47.5°.



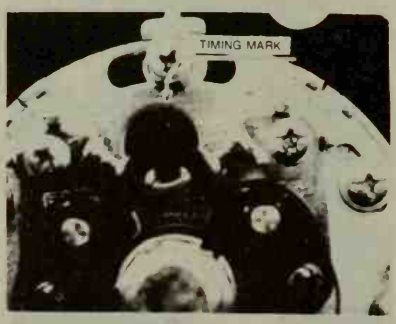
Increasing the point gap will decrease the dwell reading, and vice-versa.

Lubrication

1. It is necessary to occasionally lubricate the cam follower fiber heel and the pivot point of the contact breaker. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.
2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.
3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.
4. The lubricating wick should be adjusted so that it just contacts the breaker cam.

IGNITION TIMING (BREAKER POINT IGNITION)

The timing advance mechanism behind the breaker plate is fitted with marks which indicate piston position when they are aligned with the stationary timing mark (visible through the inspection hole in the breaker plate). There are two sets of marks, identified 1.4 and 2.3 to indicate which cylinders they represent.



Timing advance mechanism ignition timing marks

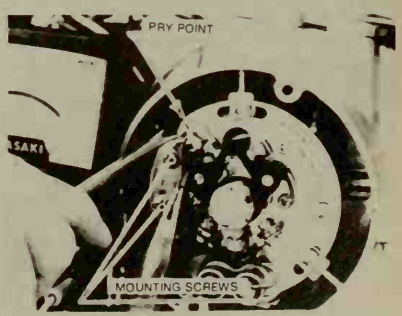
The timing marks on the advance mechanism are interpreted as follows: "T" indicates top dead center, "F" is the fixed advanced firing point, which is when the plug fires before the automatic timing advancer comes into play and is about 10° BTDC. An additional pair of

Observing the breaker plate, note that the points set on the left are marked "1.4." They control the timing for those two cylinders. The righthand points, marked "2.3," control the timing for the remaining cylinders.

Dynamic Timing

1. Clean and gap both sets of points as described previously.
2. Hook up the strobe light according to the directions of the light's manufacturer to pick up the impulses from the No. 1 (left outside) cylinder.
3. Start the engine and adjust the idle, if necessary, to the recommended idle speed.

Stationary timing mark



4. Aim the light at the timing marks visible through the inspection hole in the points base plate. At idle, the "F" mark should align with the timing index mark.
5. To check ignition timing at full advance, increase the engine speed until the motor is turning 3,000–3,400 rpm. At this point, the timing index mark should be between the two full advance marks scribed into the timing advance mechanism.
6. If adjustment is necessary, loosen the two screws which secure the 1.4 points to the breaker plate and rotate the points using a screwdriver at the pry point provided until timing is correct. Loosen the two screws just enough to allow the points to be moved.

If it is not possible to achieve correct timing by moving the points alone, center the securing screws at the median adjustment position. Then loosen the three screws which secure the breaker plate itself. Rotate the plate until the timing is corrected.

7. Repeat the procedure, this time having the strobe light pick up cylinder No. 2. If adjustment is necessary, loosen the two screws which secure points set 2.3 to its plate, and use a small screwdriver at the pry point provided to move the set so that proper mark alignment is achieved. Tighten the screws.
8. If it is not possible to achieve full advance alignment without moving the breaker base plate or points set 2.3 all the way to the end of their range of allowable travel, it is possible that the points are either incorrectly gapped, or that they are worn to the point where they must be replaced.
9. If other troubles are encountered, see "Troubleshooting" below.

Static Timing

1. Connect one of the test light or tester leads to the primary wire terminal for the points set "1.4." Ground the other lead to the engine.
2. If the test device is not self-powered, turn the ignition switch *on* and be sure the kill switch is in the "on" position as well.
3. Turn the engine over in the normal direction of rotation until the "F" mark for cylinders 1 and 4 align with the timing index mark. The test instrument should react at the instant these marks align, indicating that the points have opened. If they do not, loosen the two screws and rotate the points so that the points are just opening when the marks align. If it is not possible to do so and the points have been moved to the end of their possible adjustment range, set them at the median position and tighten the screws. Loosen the three breaker base plate screws and rotate the plate so that correct timing is achieved.
4. Repeat the procedure with points set

Adjusting the timing

2-3, first rotating the engine so that the timing marks for those cylinders are brought into alignment with the stationary timing mark. If adjustment is necessary, loosen the two screws which secure these points and rotate them so that correct timing is achieved. Tighten the screws and recheck the timing.

Troubleshooting

1. If the static method is used, the reaction of the test light or meter should be positive when the points open. If the instrument seems to hesitate before indicating that the points are open, it may be because of defective condensers or dirty or pitted points surfaces.

2. If it is necessary to move the base plate or the points plate to the extreme end of the adjustment range to effect proper timing, the points or points heel is probably worn to the limit, and the set should be replaced.

3. If the dynamic method is used, the various timing marks should hold their positions steadily at given rpms. If they seem to move erratically, check the condition of the timing advance mechanism behind the base plate. Check for weak or broken springs or stiff movement of the advancer weights. When the breaker cam is turned so that the weights move outwards, and then is released, it should return to the original position. If it does not, the springs are too weak and must be replaced. Try penetrating oil to ease movement of the mechanism if it is stiff. If this fails, replace the mechanism.

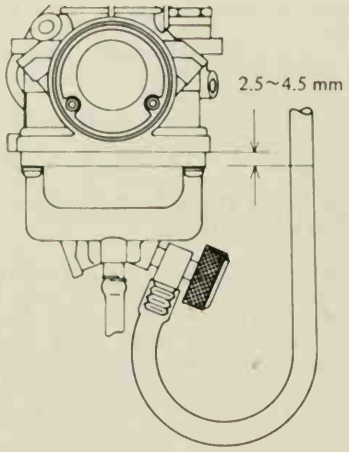
IGNITION TIMING (ELECTRONIC IGNITION)

The ignition timing is preset. No routine adjustment is required.

CARBURETORS (650)

Carburetor adjustments to be made during a tune-up include checking the float level, idle speed and mixture, and carburetor synchronization.

Adjusting Float Level



1. Float level is a measure of the amount of gasoline which will be in float bowls during operation. While it is a critical specification, it will not normally need readjustment once properly set. Float level, therefore, need not be checked at every tune-up, but should be attended to from time to time.

2. Float level is checked with the carburetors in place on the motorcycle. To do this, a special gauge (Part no. 57001-208) is needed.

3. Shut off the fuel petcock. Remove the drain plug of one of the carburetors and fit the fuel level gauge. Turn the petcock on. Fuel should flow into the float bowl until it is 2.5–4.5 mm (0.098–0.177 in.) below the edge of the carburetor body as shown in the illustration.

4. If the fuel level is not correct, remove the carburetors and take off the float bowl(s). Bend the float tang a small amount. Bending the tang up lowers the fuel level, while bending it down raises the fuel level.

5. All carburetors must have the same fuel level. Measure all before changing any. Note that the measured float level will be inaccurate if the float needle tip is worn, or if there is foreign matter on the needle seat.

Fuel level measurement

Idle Speed, Mixture, Synchronization

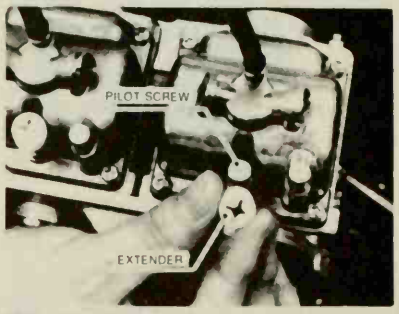
NOTE: *The following adjustments must be made when the engine is at operating temperature. Other tune-up operations (valve adjustment, ignition timing, etc.) should be performed first.*

1. Later models have pilot *air* screws on the sides of the carburetor bodies. To adjust the pilot air screws, screw each one in until it is lightly seated, then back it out two turns.

2. Early models have pilot *fuel* screws fitted under the float bowls. They are covered with plastic extenders and need not be adjusted unless they have been disturbed. In this case, remove the extenders, and turn each pilot fuel screw in until it is lightly seated, then back it out 1¾ turn. Fit the extenders so that the small ridge points towards the front.

3. After the engine has run for about five minutes to attain operating temperature, adjust the idle speed to 950–1,050 rpm by means of the idle adjusting screw.

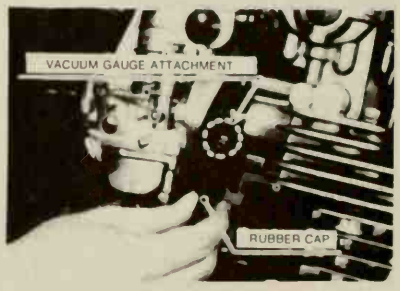
4. Remove the gas tank and supply gas to the carburetors by means of longer fuel lines. Removal of the tank is necessary to gain access to the carburetor throttle slide adjusting screws.



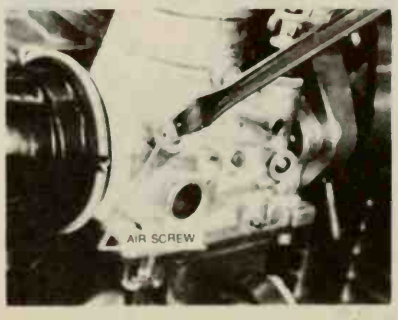
5. Remove the carburetor caps.

6. Fit the vacuum gauges to the fittings provided on the manifolds.

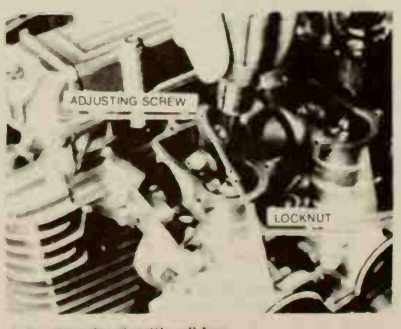
7. Start the engine and allow it to reach operating temperature.



8. With the engine running at idle, close the vacuum gauge dampers (if fitted) until needle fluctuation is less than 3 cm Hg.



9. Normal vacuum at idle should be 19–24 cm Hg. The maximum allowable difference between any two cylinders is 2 cm Hg. If adjustment is necessary, loosen the throttle slide adjusting screw locknut(s) and turn the adjusting screw(s) so that all four carburetors show the same vacuum reading. Backing the screws out decreases vacuum, while screwing them in increases it.



Pilot screw and extender

Adjusting the air screw

Adjusting the throttle slides

CARBURETORS (750)

The 750 models are equipped with four CV-type carburetors.

Adjusting Float Level

Float level is checked with special gauge Part No. 57001-1017. Correct float level is 3.0–5.0 mm (0.12–0.20 in.) below the bottom edge of the carburetor body.

Refer to the "650" section for details, if necessary. The procedure is the same, only the specification differs.

Idle Speed, Mixture, Synchronization

NOTE: *The following adjustments must be made when the engine is at operating temperature.*

1. The idle mixture is preset. Adjustment is not necessary.
2. Idle speed is 1,000–1,100 rpm and is adjusted by means of the knob between carburetors #2 and #3.
3. Remove the gas tank and supply gas to the carburetors by means of longer fuel lines.
4. Remove the rubber cap from carburetor No. 3 and disconnect the vacuum hoses from Nos. 1, 2, and 4.
5. Attach the vacuum gauges.
6. Turn the fuel petcock lever to the "PRI" position.
7. With the engine idling, close the vacuum damper valves until flutter is less than 3 cm Hg.
8. Engine vacuum at idle should be about 22 cm Hg. The difference between cylinders should be less than 2 cm Hg.
9. If the difference between any two cylinders is greater than this, use the synchronization screw between the carburetors to effect adjustment.

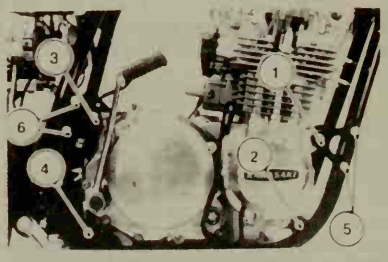
ENGINE AND TRANSMISSION

NOTE: *Engine rebuilding techniques and procedures are explained in detail in the "General Information" section.*

ENGINE REMOVAL AND INSTALLATION

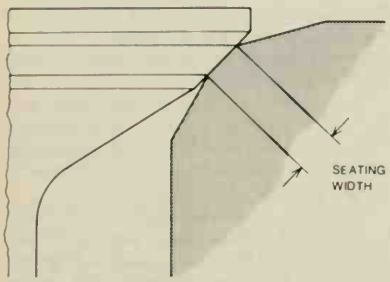


1. Drain the oil and the oil in the filter. After draining is completed, tighten the oil drain plug to 9.5–12.0 ft lbs., and the oil filter bolt to 13–16 ft lbs.
2. Remove the gas tank.
3. Remove the side covers.
4. Remove the ignition coils.
5. Disconnect the alternator 4-pin connector and the green lead. Disconnect the starter motor lead from the solenoid. Pull the solenoid off the electrical panel.
6. Remove the air cleaner housing mounting bolts from both sides of the housing.
7. Remove the baffle plate.
8. Remove the carburetor assembly.
9. Remove the ducts from the air cleaner.
10. Disconnect the breather hose from the breather cover.
11. Remove the air cleaner housing.
12. Remove the left footpeg.
13. Remove the shift lever.
14. Remove the starter motor cover.
15. Remove the two clutch cable clamps from the frame. Remove the engine sprocket cover bolts and remove the cover. Remove the cover knock pins if they remain in the crankcase.

Remove the baffle plate

16. Remove the clutch pushrod. Disconnect the neutral switch lead from the switch.
17. Disconnect the clutch cable from the hand lever. Remove the cable from the motorcycle along with the engine sprocket cover.
18. Remove both mufflers.
19. Disconnect the rear brake light spring.
20. Disconnect the battery negative lead from the engine. Disconnect the blue and brown rear brake light switch leads.
21. Disconnect the black, green, and blue/red contact breaker point leads.
22. On rear drum brake models, back off the brake adjusting nut to give the pedal plenty of play. On rear disc brake models, remove the rear brake master cylinder. Run down the brake pedal adjusting bolt to depress the pedal as much as possible.
23. Remove the right footpeg.
24. Disconnect the tach cable from the cylinder head.
25. Loosen the rear brake torque link nut, the axle nut, and back off the chain adjuster bolts. Move the wheel forward as far as possible.
26. Remove the engine sprocket nut.
27. Jack the engine up slightly to facilitate mounting bolt removal.
28. Remove the engine mounting bolts. The rear upper bolt has a spacer.

Engine mounting bolts (right side)



Removing a valve guide

tion. Heat the head to 248–302° F. Be sure the set rings are in place on the guides before installation. Be sure the guides are fully seated.

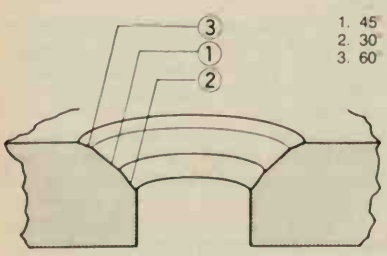
After installing a guide, it must be reamed to the proper size. Use tool No. 57001-162.

10. After installing new guides, the valve seat should be recut and the valves lapped in.

Valve seat width measurement point

Cutting

1. To determine whether the valve seat needs to be cut, carry out the following test using machinist's dye.

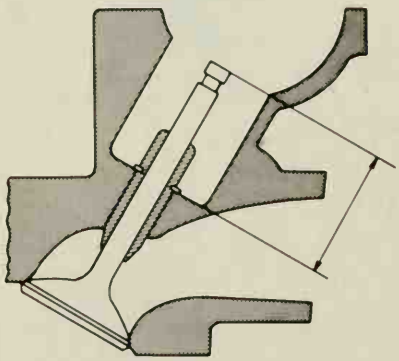


NOTE: *The valve and guide must be in serviceable condition for the test to be conclusive.*

2. Apply the dye to the valve seat and lap the valve into place. Note where the dye adheres to the valve seating surface.

3. The valve seating surface must be in the middle of the valve face. Check that the seat in the head is the proper thickness (0.5–1.0 mm/0.02–0.04 in.).

4. If the valve seat requires cutting, use a 45° cutter first. Do not cut any more material than is absolutely necessary, or it may be impossible to adjust the valves after you are done.



5. Use a 30° cutter on the *intake* valve seats to cut the surface inside the seating area. Use a 60° cutter on the surface outside the seating area. On exhaust valve seats, the 60° cutter only is required.

Valve seat profile

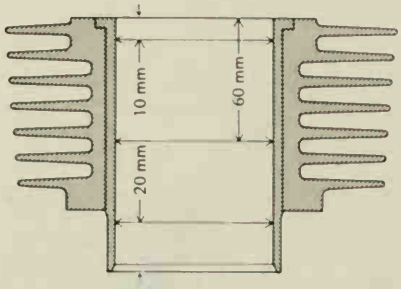
6. After the seats have been recut, lap the valves into place.

7. Install the valves and measure the distance from the spring seating area in the head to the end of the valve stem. Since cutting removes material from the valve seat, a thinner valve adjustment shim will probably have to be fitted. Refer to the accompanying chart after measuring the valve height.

Measure valve height after cutting

NOTE: *If valve height exceeds 37.54 mm no shim is available to give the correct valve clearance. In this case, replace the valve and remeasure. If a new valve does not measure less than this amount, the cylinder head must be replaced.*

Service



Valve Height Measurement (mm)	*Assembly with this shim*	*After checking valve clearance, final shim may be in this range*
36.60–36.64	2.85 mm	2.85–3.20 mm
36.65–36.69	2.80	2.80–3.20

37.50–37.54	2.00	2.00–2.35

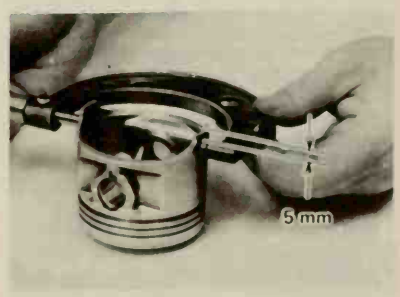
CYLINDERS AND PISTONS

1. Make a visual inspection of the cylinder bore, noting any imperfections. The cylinder walls should be uniformly smooth.

2. With an inside micrometer, measure the diameter of each cylinder bore at three places along its length. The measurement points should be about 10 mm (0.4 in.) below the top of the cylinder, 60 mm (2.4 in.) below the top, and 20 mm (0.8 in.) from the bottom of the cylinder. Make measurements in two directions, 90° apart, both parallel to and perpendicular to the piston wrist pins.

If the largest measurement exceeds 62.10 mm (2.445 in.) for 650cc machines, or 66.10 mm (2.602 in.) for 750s, or if the difference between any two measurements exceeds

Cylinder bore measurement points



0.05 mm (0.0020 in.), the cylinders must be bored out to the first oversize.

NOTE: *Maximum allowable bore size is 63.0 mm (2.4803 in.) on the 650 and 67.0 mm (2.638 in.) on the 750. If it is necessary to bore the cylinders out in excess of this figure, the cylinder block must be replaced.*

3. Make a visual inspection of the pistons. Scoring, scuffing, or seizure marks on the piston skirts may be removed with a fine grade of emery or crocus cloth if they are not too severe. Sanding should be done in a cross-hatch pattern. If the damage is severe (more than about ½ in. wide), the pistons should be replaced.

4. The rings must be free to move in the piston grooves. If they cannot, either they are carbon clogged (which necessitates replacing the rings and cleaning out the grooves), or metal has been pushed into the grooves by a piston seizure. In this event, pistons and rings must be replaced. Carbon-clogged rings are almost always broken when an attempt is made to remove or free them, so be prepared to buy a new set.

5. Measure the diameter of the pistons at a point about 5 mm (0.2 in.) from the bottom edge of the skirt and perpendicular to the wrist pin. 650 pistons should be replaced if the measured diameter is less than 61.8 mm (2.433 in.). 750 piston replacement limit is 65.8 mm (2.591 in.).

Measure piston diameter 5 mm (0.2 in.) from the bottom edge of the skirt and perpendicular to the wrist pin

6. In the event that the cylinder bore and pistons are already oversize, the serviceable limit for the bores is 0.1 mm (0.004 in.) over the size to which the cylinder was bored. The serviceable limit for oversized pistons is 0.15 mm (0.006 in.) less than the oversize. If the cylinder bore is unknown, a rough approximation can be obtained by measuring the bore diameter at the very bottom of the bore.

7. If the cylinders need boring, obtain the new pistons first. Pistons are available in 0.5 and 1.0 mm oversizes. Measure the diameter

of the pistons as explained in Step 5, above, then have the cylinders bored to that size plus the standard cylinder-to-piston clearance of 0.032–0.055 mm (0.0013–0.0022 in.) for 650 cc engines, or 0.040–0.067 mm (0.0015–0.0026 in.) for 750 cc engines.

8. When boring the cylinder block, bore the cylinders 2–4–1–3 or 3–1–4–2 to avoid heat distortion damage. Measure the diameters of the bore *after* the cylinders have cooled completely.

9. If an inside micrometer is available, measure the inside diameter of the wrist pin holes. The wrist pins should be a light push fit into the holes. If too loose, the pistons should be replaced.

Maximum allowable wrist pin hole diameter is 15.07 mm (0.5933 in.).

10. Check the condition of the wrist pins. Measure the diameter of the pins at three places along their length and compare the diameter to the service specification, the minimum allowable pin diameter is 14.96 mm (0.589 in.). Replace them if under this limit, or if they are discolored from overheating.

11. The wrist pins ride directly on the connecting rod small ends. Measure the inside diameters of the small ends and compare to the serviceable limit of 15.05 mm (0.5925 in.). If worn beyond this point, the rod must be replaced.

12. Be sure that all oil passages in the cylinder are clear.

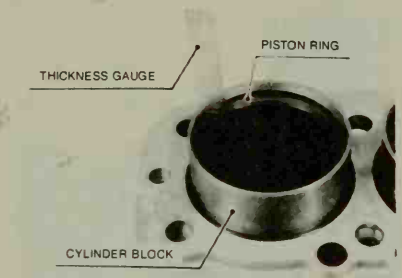
13. Replace the cylinder base O-rings. Check that any o-rings and the important knock pins fitted to the cylinders are in their proper locations before installation.

PISTON RINGS

Checks to be made on the piston compression rings include side clearance and end-gap. These checks should be made on both new and used rings.

1. Piston ring side clearance for compression rings and one-piece oil rings is checked with the rings installed on the piston. Insert a feeler gauge blade between the ring and the ring groove and check that the clearance is within the specification given:

Standard side-clearance for the top compression ring is 0.04–0.08 mm (0.0016–0.0032 in.).



Standard side clearance for the lower compression ring is 0.03–0.07 mm (0.0012–0.0028 in.).

Serviceable limit for both rings is 0.15 mm (0.0060 in.).

If the clearance is too large, the rings or grooves are worn. If too small, metal may have been pushed into the grooves due to a piston seizure. Check that the grooves are not just carboned up. If new rings do not bring the clearance to the proper value, the pistons must be replaced.

2. To remove the rings from the piston, use a ring spreader. They are available at most auto stores. Decarbonize the ring grooves.

3. To check the ring end-gap, ensure first that the cylinder bore is not excessively worn. Place each ring, in turn, into the bottom of its cylinder and push it in an inch or less using the piston skirt to align the ring in the bore. Measure the end-gap with a feeler gauge. If the end-gap is larger than the service limit, the rings must be replaced. If the measured end-gap of new rings is too large, the cylinder is worn and should be bored to the next oversize.

Checking ring end-gap

Standard end-gap is 0.15–0.30 mm (0.006–0.012 in.) for both top and second rings. The service limit is 0.7 mm (0.028 in.) for both rings.

If new rings are fitted and the end-gap is too small, the ring ends must be filed. Hold the ring steady as illustrated, closing the ends over a thin, fine file. Do not squeeze the ring, as this is the easiest way to break it. A few strokes of the file will increase the end-gap.

CAUTION: *Do not make more than a few strokes before checking the end-gap again. It is easy to remove too much metal.*

Do not allow the file to slip out of the ring, as this risks breaking it.

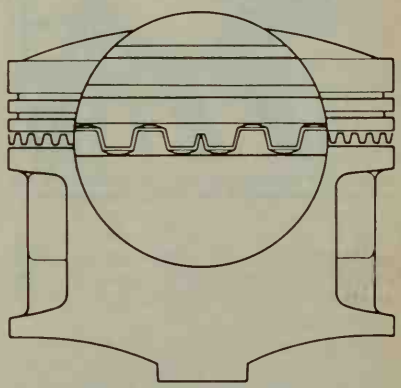
4. Check the free end gap of both compression rings. Standard is 8 mm (0.32 in.). Replace the rings if the measured free end-gap is less than 5 mm (0.20 in.).

Filing ring ends

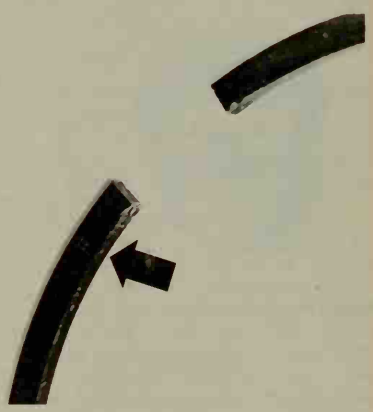
Measuring ring free end-gap

5. Roll each ring around its own groove and ensure that this can be done easily. If a ring sticks or binds in the groove, the pistons must be replaced.

6. Check piston ring groove width on the pistons.



The standard width for the top ring is 1.23–1.25 mm (0.048–0.049 in.). The service limit is 1.33 mm (0.052 in.).



For the second ring, standard groove width is 1.22–1.24 mm (0.048–0.049 in.). The service limit is 1.32 mm (0.052 in.).

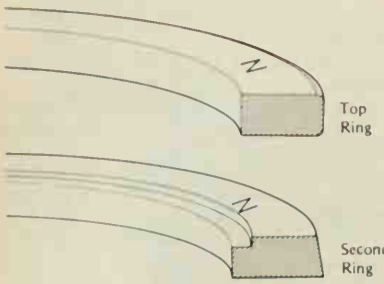
For the oil ring, standard groove width is 2.51–2.53 mm (0.099–0.100 in.). The service limit is 2.60 mm (0.102 in.).

Piston and Cylinder Installation

1. Install the oil ring expander, then the two steel oil rails. The rails are interchangeable. Be sure that the expander ends butt together.

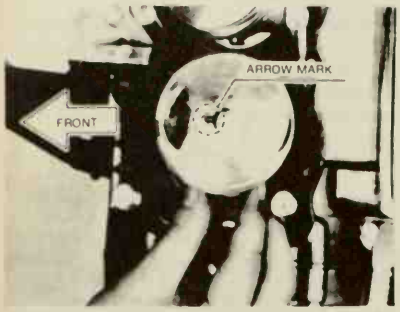
Be sure that the expander ends butt together

Always install rings so that the letter near the end-gap faces up



2. Install the compression rings so that the side marked "R" or "N" (the small letter near the end-gap) faces *upwards.*

The compression rings are interchangeable on 650 models. On the 750, the upper and lower compression rings have different profiles. Refer to the illustration.



3. Install the pistons on the rods. The arrow on the piston crown must face the front of the engine.

4. After installing the wrist pin, install the snap-rings.

NOTE: *New snap-rings must be used. Never reuse old snap-rings.*

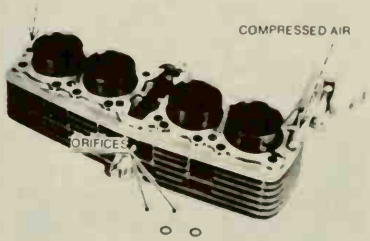
Upper and lower compression rings (750)

Install the pistons so that the arrows on the crowns point towards the front of the engine

Be sure that the snap-rings are firmly seated. When installing the snap-rings, do not compress them any more than is necessary to effect installation.

5. Arrange the piston ring end-gaps on the pistons so that the end-gap of the top ring and the oil ring expander face the front of the engine and the end-gap of the second compression ring faces the rear of the engine. The end-gaps of the two oil rails should be positioned about 30° on either side of the expander end-gap.

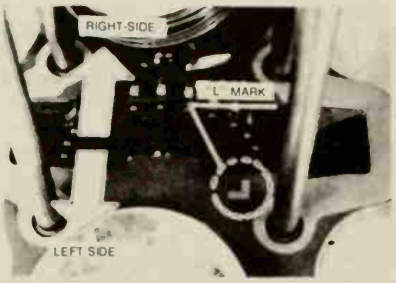
6. Lubricate the rings and piston skirts with fresh motor oil.



7. If the cam chain guide roller has been removed, install it. From engine No. KZ650BE019151, install the rubber dampers on the roller shaft ends using an adhesive with the side marked "Up" facing upwards.

Install the cam chain guide roller so that the marks face "Up"

8. Install the chain guide and tensioner sprockets in the cylinder block. From engine No. KZ650BE019151, fix the rubber dampers onto the sprocket shaft ends with an adhesive, the side marked "UP" facing upwards.

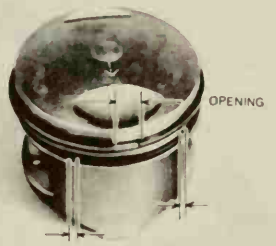


9. Blow out the oil passages and orifices in the cylinder block. Check that the two oil passage orifices are in place and that the small hole in each orifice faces up. Install the orifice o-rings.

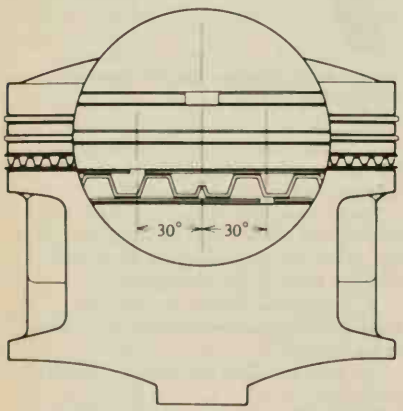
Blow out the cylinder block oil passages with compressed air. Be sure that the orifices and o-rings are fitted before installation

10. Use new cylinder base o-rings.

11. Install a new cylinder base gasket. Fit the gasket so that the "L" mark is on the left side of the cam chain cutout. Apply a liquid gasket compound to both sides of the cylinder base gasket around the rearmost section of the cam chain cutout.

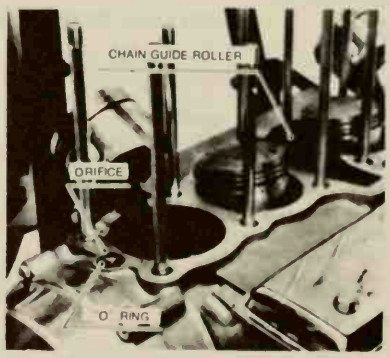


The cylinder base gasket must be installed so that the "L" mark is on the left side of the cam chain cut-out



12. Pull the cam chain taut, making sure that it is properly engaged with the crankshaft sprocket and not kinked or off the sprocket teeth.

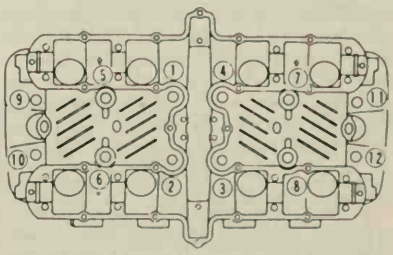
13. Turn the crank so that all of the pistons are at about the same height.



14. Install the special piston bases to hold the pistons in position. Be sure that the piston rings are properly positioned. Install the cylinder block. Piston ring compressors will facilitate the job.

Stagger the ring end-gaps

Oil rails should be arranged about 30° on either side of the expander end-gap



Be sure that the orifices, o-rings, and the chain guide roller are in place

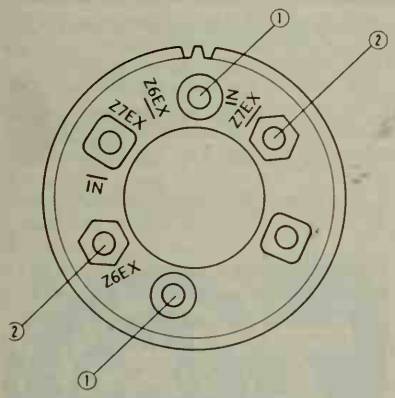
Cylinder Head Installation

1. Blow out all of the oil passages in the cylinder head with compressed air.

2. Use a new head gasket and o-rings. "Top" is marked on some head gaskets, and should be correctly positioned.

3. Install the gasket and the two o-rings. Fit the cylinder head, pulling the cam chain up through the cut-out as the head is lowered into position.

Cylinder nut tightening sequence



4. Tighten the cylinder head nuts gradually and in the order shown in the accompanying illustration. Tighten all of the nuts to about 18 ft lbs. first, then, in the pattern shown, give them a final tightening to 27–31 ft lbs.

5. Tighten the cylinder head bolts to 16–20 ft lbs. Install the valve shims and lifters in their original locations.

6. Install the camshafts as outlined below. NOTE: *If any valve service was performed, it will be necessary to adjust the valve clearance.*

Valve Timing

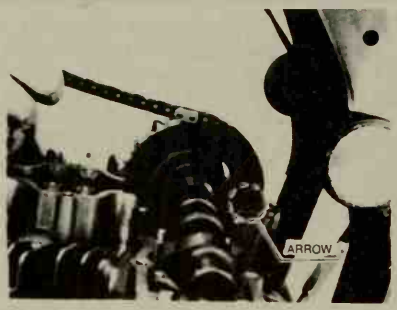
The cam sprocket timing marks are different depending on whether the engine has the older single-row cam chain, or the later hy-vo chain. The hy-vo chain is used on 750 engines and later 650s.

Hy-vo chain cam sprocket marks: (1) bolt holes for intake cam; (2) bolt holes for exhaust cam

SINGLE-ROW CAM CHAIN

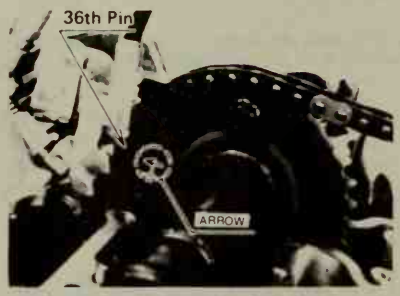
1. To install the camshafts, first make sure that the crankshaft is positioned so that the "T" mark for cylinders Nos. 1 and 4 is aligned with the stationary timing mark.

2. Pull the camshaft chain taut to remove any kinks in it. Install the exhaust camshaft noting that the notched end of the camshaft goes to the right side of the engine. Position the exhaust cam so that the arrow marked "T" on the cam sprocket is pointing towards the front of the engine and is aligned with the cylinder head surface. Keeping the cam in this position, pull the cam chain taut and loop it over the cam sprocket.



Install the cam so that the notch goes to the right side of the engine

3. Install the intake camshaft, positioning it so that the arrow marked "T" on the cam sprocket is pointing towards the rear of the engine and is aligned with the cylinder head surface.

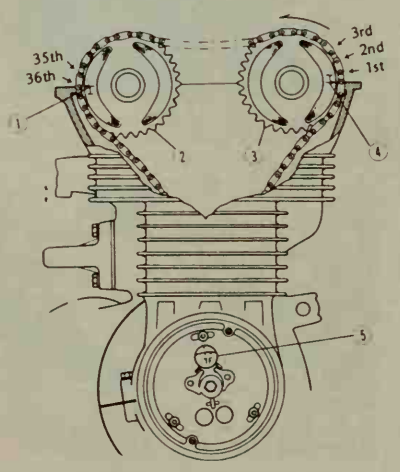


4. Find the cam chain pin pointed at by the exhaust cam "T" arrow. With this pin as "zero" count off thirty-six (36) pins. Check that the "T" arrow of the intake cam sprocket points towards this 36th pin. If it does not, the camshafts are not properly aligned, and engine damage will be the result if the engine is rotated.

5. Before installing the camshaft caps, note that the caps are identified by a number. Match the number on the cap with that on the cylinder head. Install the caps so that the arrows on the caps point towards the exhaust side of the engine.

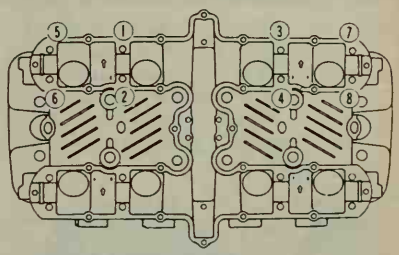
6. Partially tighten the left-inside cam caps first to seat the camshaft. Then tighten the cap bolts in the order shown in the illustration until the proper torque of 7.9–10.8 ft lbs. is reached.

Align the arrow marked "T" with the cylinder head surface



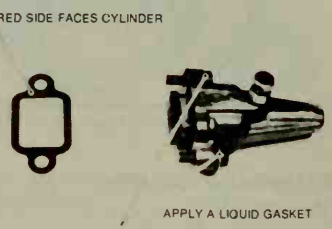
The arrow marked "T" of the intake cam sprocket must be aligned with the cylinder head surface and indicate the 36th cam chain pin

7. Install the upper chain guide sprocket assembly and tighten the allen bolts to 6.5–7.9 ft lbs. The bolts should be secured with a non-permanent thread-locking compound.



8. Install the cam chain tensioner assembly. Note that the red side of the assembly gasket must face the cylinder. Apply liquid gasket to both sides of the assembly bolt washers. Tighen the bolts evenly to 5.1–6.5 ft lbs.

9. Recheck the valve timing before rotating the engine. Turn the engine over slowly at first. If any resistance is felt, stop at once and determine the cause. Improper valve timing may cause the valves to hit the pistons or each other. Turn the engine through several complete revolutions and realign the "T" mark for cylinders Nos. 1 and 4. Check that the cam sprocket marked are still aligned as before.



1. T-marked Arrow
2. Inlet Camshaft Sprocket
3. Exhaust Camshaft Sprocket
4. T-marked Arrow
5. #1, 4 TDC Mark

Valve timing alignments

Cam cap bolt tightening sequence

Install the chain tensioner gasket so that the red side faces the cylinder. Use liquid gasket compound on the tensioner bolts

10. Apply a small amount of high temperature grease to the tachometer pinion shaft, and insert the pinion and pinion holder into the cylinder head. Secure the pinion holder with the holder stopper and screw.

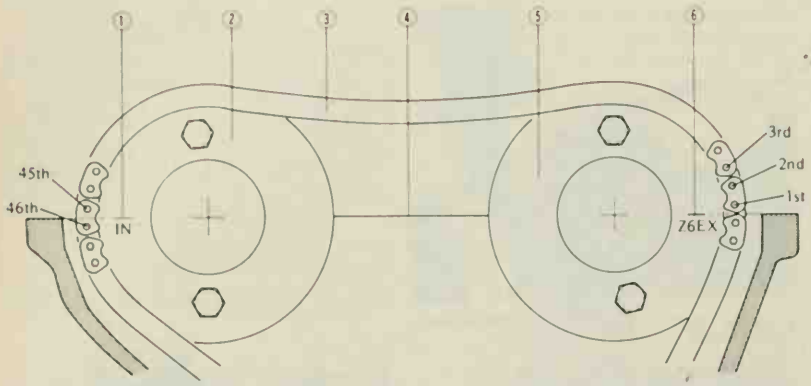
11. Lubricate all of the top end components before refitting the cylinder head cover.

12. Recheck the valve clearance.

13. After the engine has been completely reassembled, start it and allow it to reach operating temperature. Then let it cool completely and retorque the head nuts and bolts.

HY-VO CAM CHAIN

This procedure applies to 750 cc engines, and later 650s.



1. First make sure that the crankshaft is positioned so that the "T" mark for cylinders Nos. 1 and 4 is aligned with the stationary timing mark.

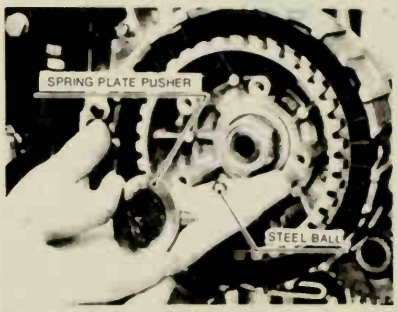
2. Pull the cam chain taut to remove any kinks in it. Install the exhaust camshaft noting that the notched end of the camshaft goes on the right side of the engine. Position the exhaust cam so that the line marked "Z6EX" on 650 engines or "Z7EX" on 750 engines is pointing towards the front of the engine and aligned with the cylinder head surface. Keeping the camshaft in this position, pull the chain taut and loop it over the cam sprocket.

3. Install the intake cam, and align the line marked "IN" with the cylinder head surface and pointing towards the rear of the engine.

4. Find the cam chain pin pointed at by the exhaust camshaft sprocket line marked "Z6EX" or "Z7EX." With this pin as "zero," count off forty-five (45) pins. Check that the "IN" mark points between the 45th and 46th pins. If it does not, the camshafts are not properly aligned, and engine damage will result if the engine is rotated. Refer to the illustration.

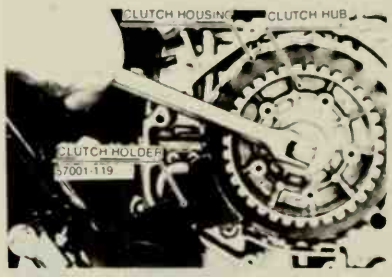
5. The remainder of the procedure is the same as described for single-row cam chain models, above Steps 5–13.

Correct valve timing for hy-vo chain models: (1) IN mark; (2) intake cam sprocket; (3) cam chain; (4) cylinder head surface; (5) exhaust cam sprocket; (6) Z6EX mark for 650s; 750s are marked Z7EX



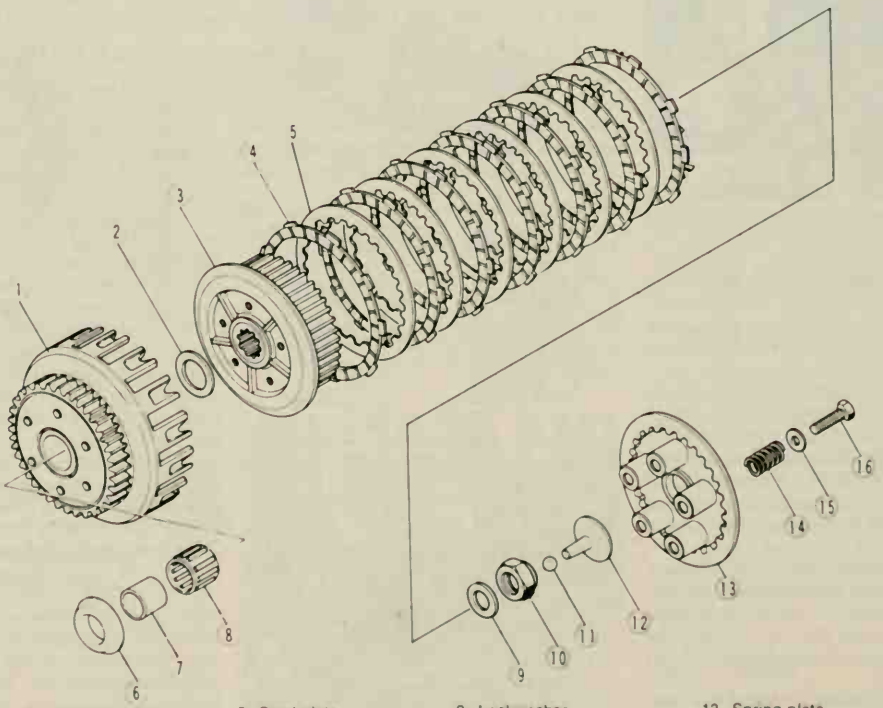
CRANKCASE COVER COMPONENTS

The following section deals with the removal, inspection, and installation of those components found beneath the left and right crankcase covers. These include the clutch, breaker points, alternator, clutch release mechanism, engine sprocket, external shift assembly, and kickstarter spring. These components can all be serviced with the engine in the frame.



Clutch

REMOVAL



1. Drain the oil. Refit the drain plug and tighten it to 9.5–12.0 ft lbs.
2. Disconnect the rear brake light switch spring.
3. On drum rear brake models, back off the brake adjusting nut to give the pedal plenty of play. On disc rear brake models, remove the master cylinder. Loosen the pedal height adjusting bolt locknut and turn the bolt to hold the pedal down and out of the way.
4. Remove the right side footpeg.
5. Mark the position of the kickstarter relative to its shaft, then remove it. It may be necessary to spread the kickstarter clamp slightly after removing the pinch bolt so that it can easily be removed from the kickstarter shaft splines.
6. Detach the contact breaker leads from the clamps below the clutch cover.
7. Remove the ten clutch cover screws, and take off the clutch cover and its gasket.
8. Remove the clutch spring bolts, washers, and springs.
9. Remove the spring plate, take out the plate pusher, and tilt the motorcycle to the right so that the steel ball will come out.
10. Remove the clutch plates.
11. Stop the clutch hub from turning using the special tool, or a suitable substitute, and remove the clutch hub nut and its lockwasher.
12. Remove the clutch hub, housing, needle bearing, drive shaft sleeve, and spacer.

Removing the spring plate pusher and steel ball

Removing the clutch hub nut

1. Clutch housing
2. Thrust washer
3. Clutch hub
4. Friction plate
5. Steel plate
6. Spacer
7. Sleeve
8. Needle bearing
9. Lockwasher
10. Nut
11. Steel ball
12. Spring plate pusher
13. Spring plate
14. Clutch spring
15. Washer
16. Bolt

Clutch assembly

Note the thrust washer between the hub and housing.

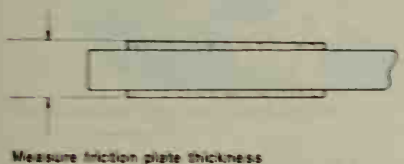
INSPECTION

The following checklist may help to diagnose clutch trouble.

If the clutch does not disengage properly, this may be caused by:

a. Excessive lever play/cable adjustment.
b. Warped or rough clutch plates.
c. Uneven clutch spring tension.
d. Deteriorated engine oil.
e. Too much oil in the engine, or oil of too high a viscosity.
f. Clutch housing frozen on the drive shaft.
g. Defective clutch release mechanism.
h. Unevenly worn clutch hub or clutch housing.

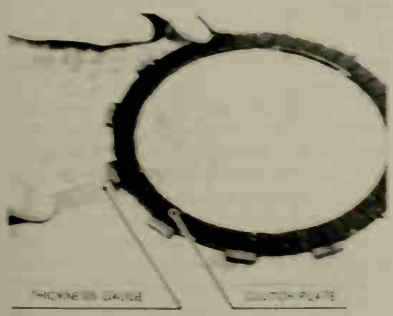
If the clutch slips, some possible causes are:



a. Insufficient cable play.
b. Worn friction plates.
c. Weak clutch springs.
d. Sticking clutch cable.
e. Defective clutch release mechanism.
f. Unevenly worn clutch hub or clutch housing.

Too much noise in the clutch can be caused by:

a. Excessive shaft/clutch gear backlash.
b. Damaged gear teeth.
c. Excessive friction plate/housing clearance.
d. Worn or damaged housing needle bearing.
e. Weak or damaged damper rubbers.
f. Metal particles in the housing gear teeth.

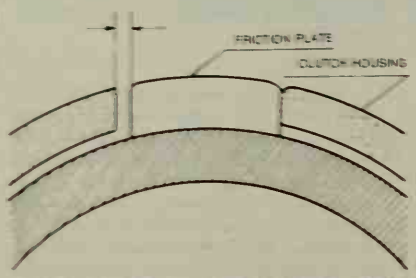


1. Check the lengths of each of the clutch springs. If one or more of the springs is shorter than the others, replace the set.

2. Check the thickness of each of the clutch friction plates. Standard thickness is 3.7–3.9 mm (0.146–0.154 in.). Replace the plates as a set if any of them measures less than 3.5 mm (0.138 in.).

Measure friction plate thickness

3. Place each steel and friction plate on a flat surface, such as a piece of glass, and check plate warpage by attempting to slip feeler gauge blades between the plate and the glass.



Checking a friction plate for warpage

Replace the friction plates as a set if any of them is warped more than 0.3 mm (0.012 in.).

Replace the steel plates if any of them is warped more than 0.4 mm (0.016 in.).

Standard warpage is less than 0.15 mm (0.006 in.) for the friction plates and less than 0.20 mm (0.008 in.) for the steel plates.

4. Measure the clearance between the friction plate tangs and the clutch housing. Standard clearance is 0.34–0.75 mm (0.0133–0.0295 in.). Replace the friction plates if the clearance exceeds 1.0 (0.4 in.).

Measure the clearance between the friction plate tabs and the clutch housing

5. Check the clutch housing for wear caused by the tangs of the friction plates. Minor indented wear can be removed with an oilstone. If the indentations are too deep, however, the housing should be replaced.

6. Check the condition of the clutch housing gear teeth. Minor damage to the teeth can be removed with an oilstone. If this is not possible, the housing must be replaced. If the housing gear teeth shows signs of wear, inspect the secondary shaft gear as well. The gears should be replaced as a set.

Minor imperfections on the clutch housing gear teeth can be removed with an oilstone

Checking clutch housing-to-secondary shaft gear backlash

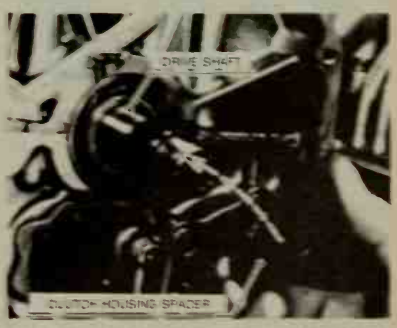
7. With a dial gauge, measure clutch housing gear/secondary shaft gear backlash. Standard gear backlash is under 0.08 mm (0.0031 in.). If the measured backlash exceeds 0.12 mm (0.0047 in.), replace the clutch housing and the secondary shaft gear.

8. Measure the diameter of the drive shaft sleeve. Standard diameter is 31.980–31.995 mm (1.2590–1.2856 in.). Replace the sleeve if the diameter is less than 31.96 mm (1.258 in.).

Measuring drive shaft sleeve and clutch housing inside diameter

9. Measure the inside diameter of the clutch housing. Standard diameter is 37.000–37.016 mm (1.4567–1.4573 in.). Replace the housing if the measured diameter is greater than 37.05 mm (1.458 in.).

10. Check the condition of the housing needle bearing and replace it if it is blued or discolored, or if rotation is faulty, or there are flat spots on the needles.



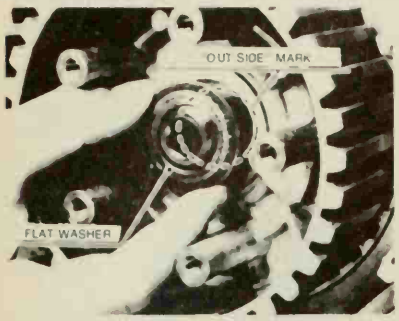
11. If the clutch housing or the drive shaft sleeve are ever replaced, the needle bearing should be replaced as a matter of course.

12. Check the splines of the clutch hub where the steel plates ride. Minor wear can be repaired with an oilstone. If damage is excessive, the hub should be replaced.

13. Check the fit of the hub on its shaft. It should be fairly tight. If the hub is very loose, check the inner splines for damage, and replace the hub if necessary.

ASSEMBLY

1. Install the clutch housing spacer on the drive shaft. The spacer must be installed so that the flat side faces *outwards*.



Install the clutch housing spacer so that the flat side faces outwards

2. Install the drive shaft sleeve, the needle bearing, and the clutch housing.

3. Install the thrust washer, the clutch hub, the hub nut washer and the hub nut. Note that the hub nut washer must be installed with the side marked "Outside" facing outwards. A new hub nut should be used. Tighten the hub nut to 87–118 ft lbs.

4. Install one of the friction plates, then alternate steel and friction plates until all are fitted. New plates should be generously coated with fresh engine oil before installation.

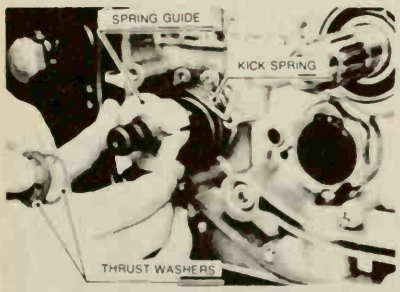
Fit the hub nut washer with the "Outside" mark facing out

5. Fit the steel ball and pusher. They should be lubricated with a high melting-point grease.

6. Install the spring plate, washers, and the bolts. Tighten the bolts in a cross pattern to 6.5–7.9 ft lbs.

7. Make sure that the two thrust washers are in place on the kickstarter shaft. Check that the two clutch cover knock pins are in place. Fit a new cover gasket, and install the cover. Lubricate the lips of the kickstarter shaft oil seal before installation to avoid damaging the seal. An oil seal guide (57001-265) can also be used.

8. The remainder of the procedure is the reverse of removal.

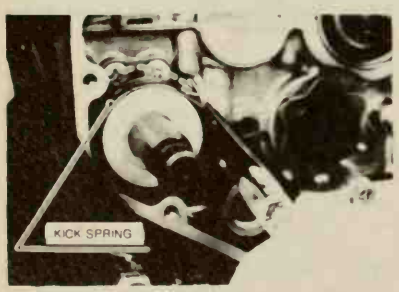


Kickstarter Spring

REMOVAL

1. Remove the clutch cover. Remove the clutch assembly.

2. Pull off the thrust washers and the spring guide.



3. Remove the kickstarter return spring.

Removing the thrust washers and spring guide

INSPECTION

1. Replace the spring if it is broken, or so weakened that it cannot hold the kickstarter lever firmly in place.

Installing the kickstarter return spring

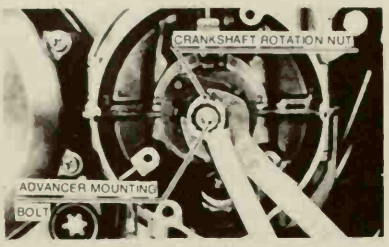
INSTALLATION

1. Turn the kickstarter shaft as far as possible clockwise, insert one end of the return spring into the shaft, insert the spring guide, and install the other end of the spring into the crankcase hole using a pair of needle-nosed pliers.

2. Install the two thrust washers. The thinner washer is installed on the shaft first.

3. The remainder of the procedure is the reverse of removal.

Timing Advance Mechanism



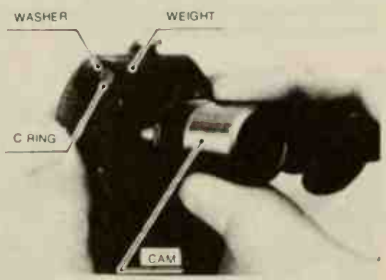
REMOVAL

1. Remove the contact breaker point cover.

2. Remove the three contact breaker mounting plate screws and take off the plate.

3. Disconnect the oil pressure indicator switch lead.

4. Use a 17 mm wrench on the crankshaft rotation to keep the engine from turning over and remove the timing advancer mounting bolt. Take off the rotation nut and the timing advance mechanism.



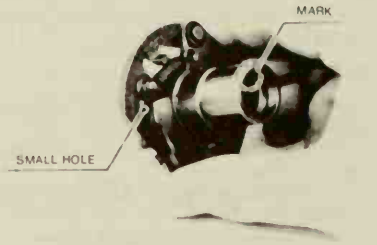
Removing the timing advancer mounting bolt

INSPECTION

1. Refer to "Tune-Up," for breaker point inspection.

2. The timing advance mechanism springs should have enough tension to return the breaker cam to its original position when it is turned as far as possible and then released. If they cannot, replace the springs if lubricating the assembly will not ease the movement.

3. If disassembly of the unit is desired, take off the breaker cam. Remove the two C-rings, washers, and weights. Remove the thrust washers from the shafts.



Timing advance unit components

INSTALLATION

1. Clean the advance mechanism thoroughly, and fill the groove in the advancer body with grease.

2. When installing the breaker cam, align the mark on the cam with the small hole in the timing advance mechanism body.

When fitting the breaker cam, align the mark on the cam with the small hole on the body

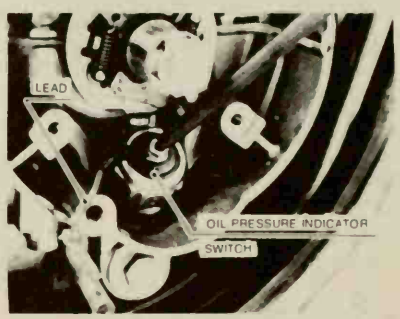
3. When installing the timing advance mechanism on the crankshaft, match the notch in the mechanism with the pin on the end of the crank.

4. Install the crankshaft rotation nut and the advancer mounting bolt. The notches in the nut fit the projections of the timing advance mechanism.

5. Tighten the bolt to 16.5–19.5 ft lbs.

6. Connect the oil pressure indicator switch lead. The lead must point towards the rear.

7. Install the contact breaker mounting plate. Adjust the ignition timing.



Oil Pressure Indicator Switch

REMOVAL

1. Remove the timing advance mechanism.

2. Remove the bolt and lockwasher and remove the lead from the switch.

3. Unscrew and remove the switch.

Disconnecting the oil pressure indicator switch lead

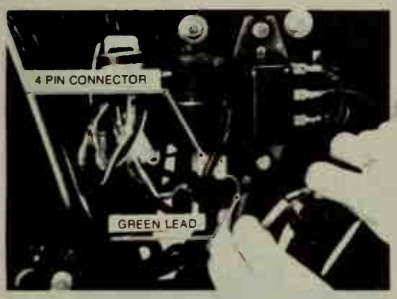
INSTALLATION

1. Tighten the switch to 9.5–12.0 ft lbs.

2. The switch lead must point towards the rear.

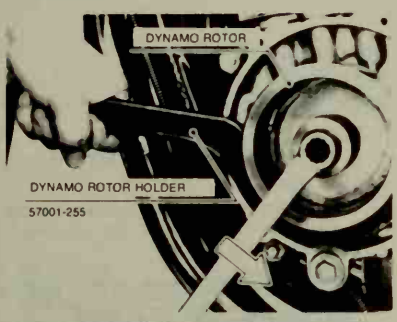
Alternator

REMOVAL



1. Remove the left side-cover and disconnect the alternator 4-pin connector and the green lead.

2. Remove the engine sprocket cover. Disconnect the neutral indicator switch lead. Pull the alternator wiring harness out to the left.



3. Remove the alternator cover screws and remove the cover and gasket.

4. If desired, remove the three allen bolts which secure the armature windings to the cover and remove the armature. Remove the three field coil allen bolts and take out the field coil.

5. Hold the rotor steady with the special

Disconnecting the green lead

Removing the alternator rotor bolt

tool, or by placing the engine in gear and applying the rear brake, and remove the rotor bolt.

6. Holding the rotor steady as before, remove the rotor with the special tool (No. 57001-254).

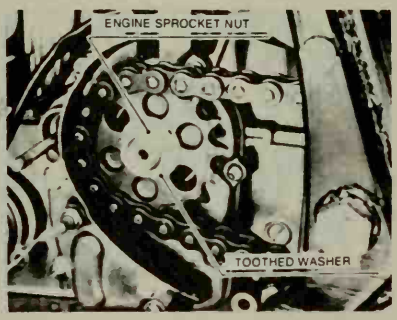
INSTALLATION

1. Installation is basically the reverse of removal. Note the following points:

a. Be sure that the crankshaft taper is perfectly clean and free of oil or foreign matter.

b. Tighten the rotor bolt to 42–46 ft lbs.

c. Apply a non-permanent thread-locking compound to the armature and field coil allen bolts if these components were removed. Use a liquid gasket compound around the wiring grommets.



d. Check that the two knock pins are in place before installing the cover.

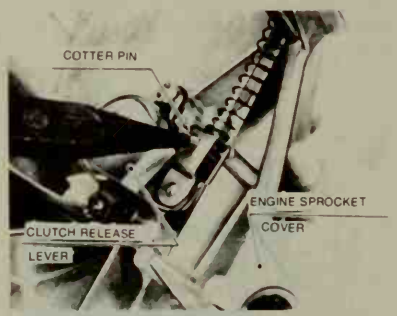
e. Route the alternator wiring harness between the external shift mechanism cover and the crankcase.

Engine Sprocket

REMOVAL

1. Remove the left footpeg.
2. Remove the shift lever pinch bolt and pull off the shift lever.
3. Remove the starter motor cover.
4. Remove the engine sprocket cover.
5. Remove the axle nut cotter pin and loosen the axle nut.
6. Remove the cotter pin or safety clip and loosen the rear torque link nut.
7. Loosen the chain adjuster bolt locknuts and back off the chain adjuster bolts as far as possible. Push the wheel forward.
8. Bend down the locking tab on the engine sprocket nut. Hold the engine sprocket in place using either the special tool (57001-306) or by putting the machine in gear and applying the rear brake. Remove the sprocket nut. Pull the sprocket off its shaft with the chain attached.

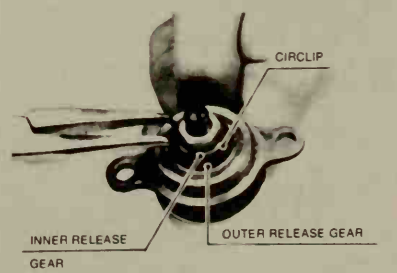
INSTALLATION



1. Install the sprocket onto the shaft with the chain looped around it.
2. Fit the lockwasher, engaging it with the hole in the sprocket. Install the sprocket nut and tighten it to 54–61 ft lbs. Bend down a tab of the washer over one of the flats of the nut.
3. Check that the knock pin is in place and install the sprocket cover. Use the shift shaft oil seal guide (57001-266) if possible.
4. Fit the shift lever, aligning it so that the pedal is even with the alternator cover lower right bolt.
5. Fit the footpeg. Adjust the clutch.

Clutch Release Mechanism

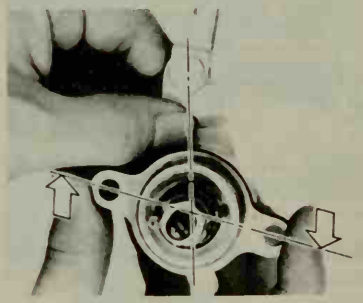
The clutch release mechanism is inside the engine sprocket cover.



REMOVAL

1. Remove the engine sprocket cover.
2. Remove the cotter pin from the release lever and disengage the cable from the fitting.

Removing the cable cotter pin

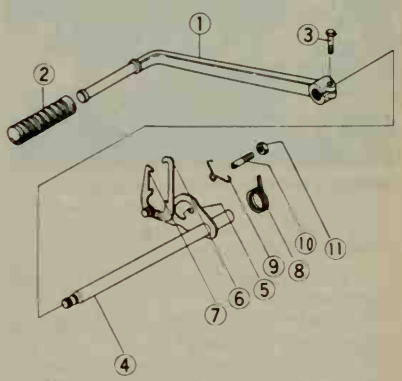


3. Remove the two mounting screws and take out the release mechanism.
4. Remove the circlip. Separate the inner and outer release gears.

Removing the clutch release mechanism circlip

INSTALLATION

1. Clean the release balls in a solvent and lubricate them with chassis grease. There are eleven balls.
2. Fit the inner gear onto the outer gear. When fully meshed, the release lever and the outer gear must be positioned as shown in the illustration. The machined side of the outer gear must face upwards. Install the circlip.



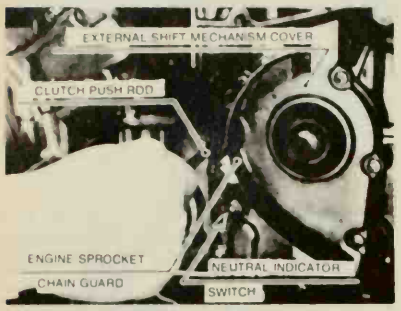
Align the release lever and the outer gear as shown

3. Use a non-permanent thread-locking compound on the release mechanism mounting screws.
4. The remainder of the procedure is the reverse of removal. Adjust the clutch after installation is completed.

External Shift Mechanism

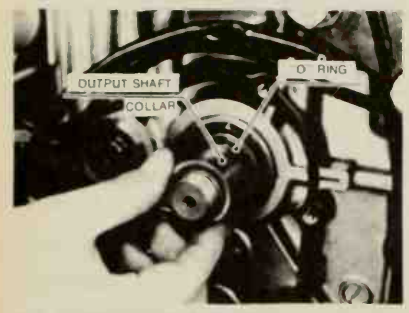
REMOVAL

1. Remove the engine sprocket cover. Remove the engine sprocket cover. Remove the engine sprocket.
2. Disconnect the neutral indicator switch lead. Remove the clutch pushrod.



1. Shift pedal
2. Pedal rubber
3. Bolt
4. Shift shaft
5. Shift lever
6. Overshift limiter
7. Shift mechanism arm
8. Return spring
9. Pawl spring
10. Return spring pin
11. Locknut

External shift mechanism assembly



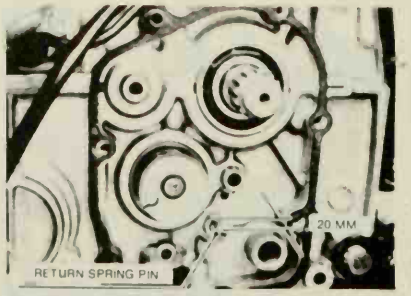
3. Remove the engine sprocket chain guard.
4. Place a suitable container beneath the cover to catch the oil which will drain off. Remove the seven shift mechanism cover screws and pull off the cover. Install one of the screws in its hole to stop the oil flow.
5. Remove the output shaft collar. If the collar is difficult to remove, use a bearing puller. Remove the o-ring.

6. Disengage the shift mechanism arm and the overshift limiter arm from the shift drum and pull out the external shift mechanism.

CAUTION: *Do not pull the shift rod out of the crankcases more than 40 mm (1.6 in.) or the shift forks will fall into the oil pan, requiring splitting the crankcases.*

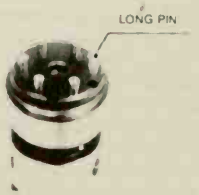
Removing the clutch push rod

Removing the output shaft collar



Removing the external shift mechanism

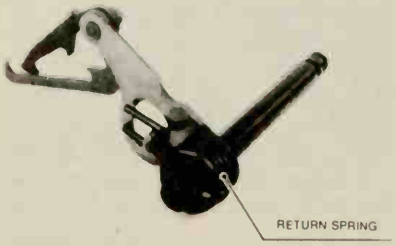
INSPECTION



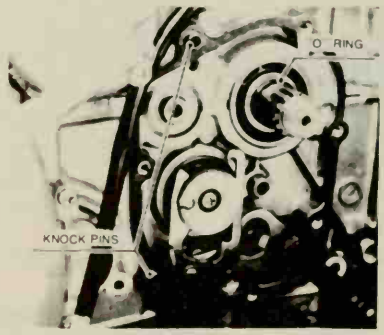
1. Check the shift mechanism and overshift limiter arms for wear.
2. Check the return spring for damage, and replace it if it is broken.
3. Check that the shift drum pins are not broken or worn.
4. Check that the output shaft o-ring is in good condition.
5. Check that the return spring pin is secure in the cases. If not, remove it and reinstall with a non-permanent thread-locking compound on the threads. The pin should protrude about 20 mm (0.8 in.) from the crankcases.

INSTALLATION

1. Check that the return spring is properly fitted to the shaft.
2. If the shift drum pins have been removed, check that the long pin is installed in the position shown.

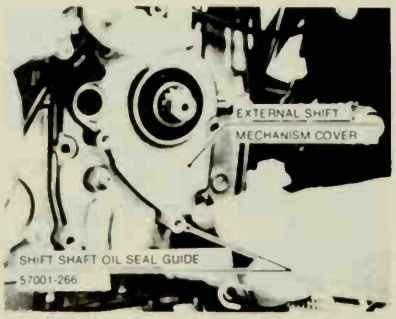


The return spring pin should protrude 20 mm (0.8 in.) from the case



Correct position of the long shift drum pin

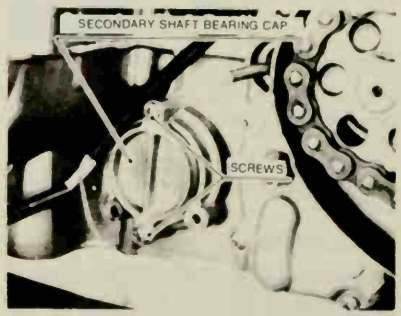
3. Install the external shift mechanism shaft, engaging the arms with the shift drum pins.



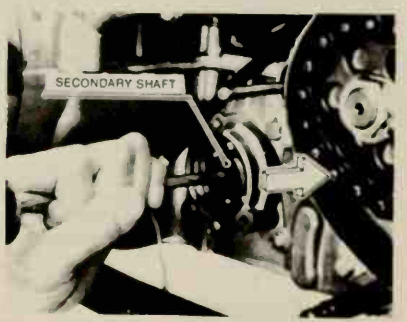
Return spring installation

Knock pins and o-ring in position

4. Check that the two knock pins are in place in the crankcase.
5. Install the shaft o-ring.
6. Apply high-temperature grease to the lips of the clutch pushrod oil seal and the output shaft collar oil seal.
7. Use the shift shaft oil seal guide (57001-266), and install the cover. The aluminum washer for the lower left screw must be replaced with a new one.
8. Install the output shaft collar.
9. Install the chain guard, using a non-permanent thread-locking compound on the threads.
10. The remainder of the procedure is the reverse of removal.



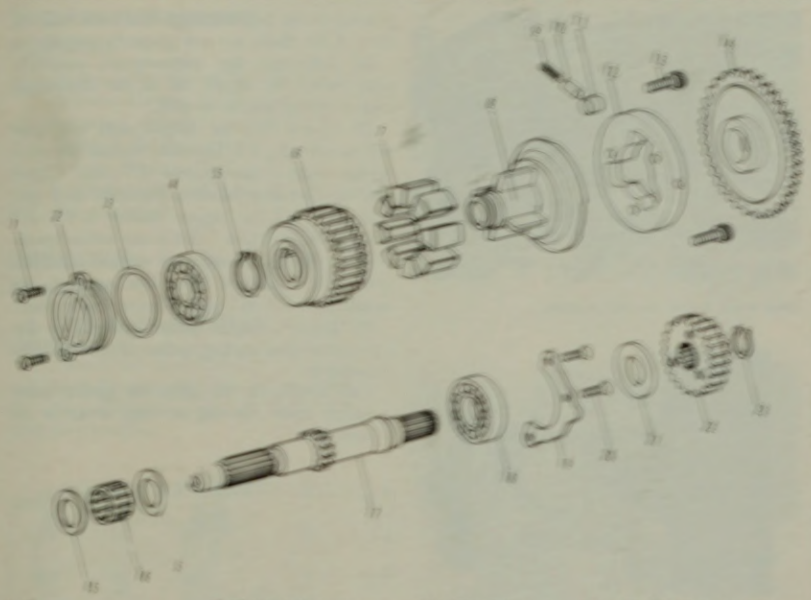
Installing the external shift mechanism cover



Secondary Shaft/ Starter Motor Clutch

REMOVAL

1. Remove the mufflers.
2. Remove the engine sprocket cover, clutch, and oil pump.
3. Remove the secondary shaft bearing stopper screws and pull off the secondary shaft.



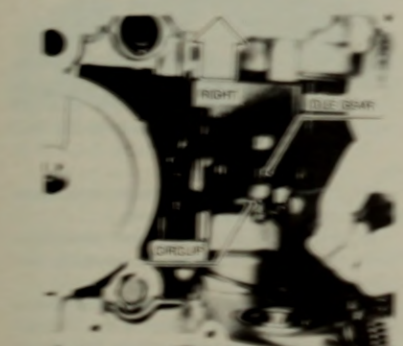
Remove the secondary shaft bearing cap

Tap the left side of the secondary shaft inwards to remove the right-side bearing

4. Remove the two screws and remove the secondary shaft bearing cap.
5. Tap the left side of the secondary shaft inwards until the right-side bearing comes out.
6. Hold the secondary sprocket and starter clutch assembly together and remove the shaft.
7. Disengage the secondary sprocket and starter clutch assembly from the primary chain and remove them from the bottom of the engine.
8. Remove the secondary shaft gear circlip. Use a bearing puller to remove the gear from the shaft.
9. If removal of the starter motor idler gear is desired, remove the circlip, pull off the shaft, and remove the idler gear.

1. Screw
2. Bearing cap
3. O-ring
4. Ball bearing
5. Circlip
6. Secondary sprocket
7. Rubber damper
8. Inner coupling
9. Spring
10. Spring cap
11. Roller
12. Starter motor clutch
13. Allen bolt
14. Starter clutch gear
15. Washer
16. Needle bearing
17. Secondary shaft
18. Ball bearing
19. Bearing stopper
20. Screw
21. Thrust washer
22. Secondary shaft gear
23. Circlip

Secondary shaft assembly



Removing the secondary sprocket and starter motor clutch assembly

10. To disassemble the shaft, remove the starter clutch gear, needle bearing, and washer.

11. Remove the rollers, spring, and the three spring caps from the starter motor clutch.

12. Remove the circlip and pull off the secondary sprocket. Note the rubber dampers.

Removing the starter motor idler gear

13. While holding the coupling steady, remove the three allen bolts to separate the coupling and the starter motor clutch.

INSPECTION

1. Check the condition of the bearings. Rotation should be smooth and effortless. If damage is noted, or if there is play between the inner and outer races, replace the bearings.

2. Check the secondary shaft sprocket teeth. Minor damage can be remedied with an oilstone. Extensive damage or wear, however, necessitates replacement of the sprocket. If this is necessary, check the primary chain as well, since it, too, is probably worn.

INSTALLATION

1. Install the idler gear if it was removed. The gear must be installed so that the protruding side points to the right.

2. Reassemble the secondary shaft components, referring to the diagram for proper assembly order if necessary. Apply some oil to the rubber dampers before fitting.

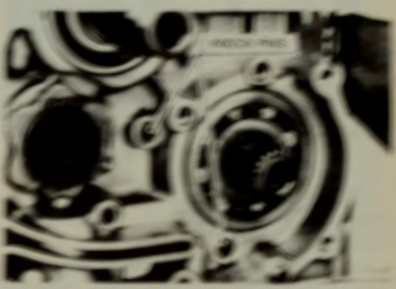
3. Use a non-permanent thread-locking compound on the allen bolt threads and tighten the bolts to 24-27 ft lbs.

4. Install the thrust washer, starter motor clutch, and needle bearing assembly into the secondary sprocket and starter motor clutch assembly.

5. Engage the primary chain around the sprocket.

6. Install the thrust washer onto the secondary shaft and put the secondary shaft into the sprocket assembly.

7. Install the shaft bearing on the right side of the engine using a bearing driver or suitable substitute. Press the bearing in until it is fully seated.



8. Be sure that the oil pump knock pins are in place.

Engaging the primary chain with the secondary sprocket

Installing the secondary shaft

Be sure that the oil pump knock pins are in place

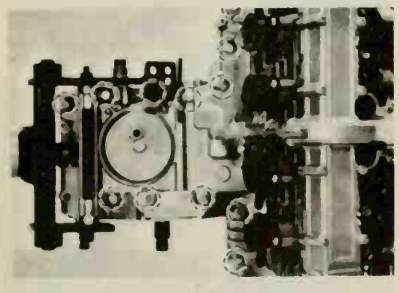
9. Install the secondary shaft bearing stopper with the two short screws and tighten the screws lightly. Install the oil pump, making sure that the gears mesh correctly.

10. Apply a non-permanent thread-locking compound to the oil pump bolt and tighten the bolt and the two screws. Then tighten the secondary shaft bearing stopper screws. Bend each screw to prevent loosening.

11. Fit the secondary shaft bearing cap.

12. Install the large flat washer onto the secondary shaft. Oil the shaft and press on the gear. A special gear installation tool (57001-329) is available. Install the circlip.

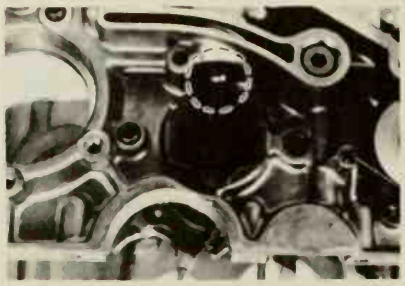
13. The remainder of the procedure is the reverse of removal.



LOWER END AND TRANSMISSION

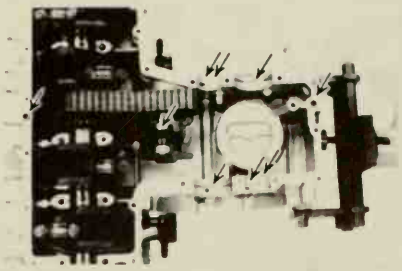
Splitting the Crankcases

If the transmission alone is to be serviced, it is not necessary to remove the top end components. If the crankshaft must be taken out, however, the top end (cylinder head, cylinders, pistons) must be removed.

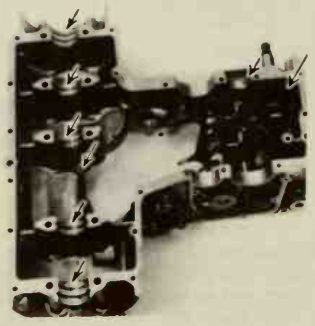


1. Remove the engine from the frame.

2. Remove the starter motor. Disconnect the neutral indicator switch.
3. Remove the alternator cover. Remove the alternator rotor if the crankshaft is going to be serviced.
4. Remove the engine sprocket chain guard. Remove the external shift mechanism cover.
5. Remove the output shaft collar, using a bearing puller if it is difficult to remove.
6. Remove the external shift mechanism.
7. Remove the secondary shaft bearing cap.
8. Remove the contact breaker assembly. Disconnect the oil pressure switch lead. Remove the timing advance mechanism.
9. Remove the clutch assembly.
10. Remove the secondary shaft bearing stopper screws.
11. Remove the twelve upper crankcase bolts.

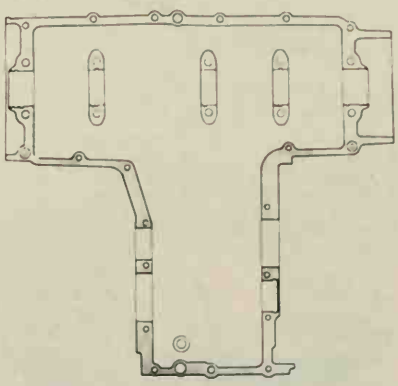


Upper crankcase half bolts



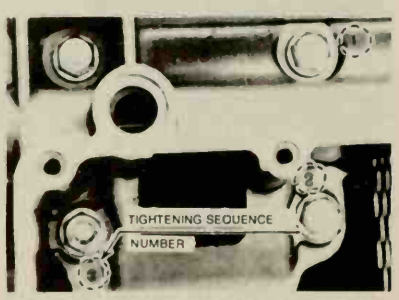
12. Remove the oil filter. Remove the oil pan, gasket, and oil passage o-rings. There are three of them.
13. Remove the oil pump.
14. Remove the secondary shaft and starter motor clutch assembly. Refer to the section above for removal details.
15. Remove the eight 6 mm lower crankcase bolts and the two 8 mm bolts. Split the crankcases. Pry at the two indicated pry points if necessary.
16. Upper and lower crankcase halves are machined together. Therefore, they must be replaced in a set.
17. The 8 mm lower crankcase bolts should be replaced after five removals.
18. To install the cases, first set the shift drum in the neutral position.
19. Check that the following pieces are in place in the upper crankcase half: two knock pins, drive shaft and output shaft set rings and set pins, oil passage plug, and starter motor idler gear.
20. Check that the following components

Shift drum in the neutral position



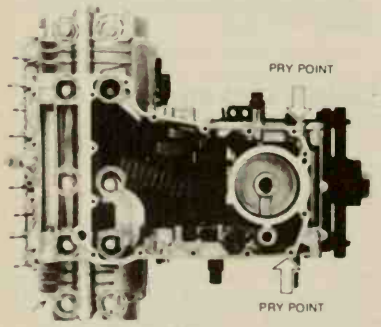
Be sure that the indicated components are in place

Bearing inserts, oil passage nozzles, and kickstarter assembly



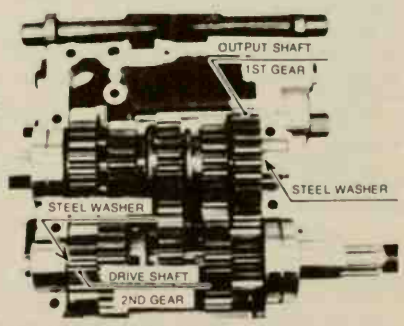
are in place in the lower crankcase half: kickstarter shaft assembly, two oil passage nozzles, five crankshaft main bearing inserts.
21. Blow oil passages in the cases clear with compressed air.
22. Be sure that the crankcase mating surfaces are clean and dry, and free of old gasket material.
23. Install the transmission shafts in the upper crankcase half. Be sure that the crankcase set pins engage the holes in the needle bearing outer races and the set rings into the grooves in the ball bearings. The cases will not mate if the shafts are not properly seated.
24. Lubricate the transmission assembly with motor oil. Apply oil to the crankshaft main bearing inserts as well.
25. Check that the output shaft first gear will turn freely. If it does not, replace the steel washer with a thinner one (0.5 mm). Check that the clearance between the drive shaft second gear and the copper washer is 0.1–0.3 mm (0.004–0.012 in.). If it is not within specification, change or add steel washers until the clearance is correct. The steel washers are available in 1.0, 0.7, and 0.5 mm thicknesses.
26. Apply a liquid gasket material to the lower crankcase mating surface as shown in the illustration.

CAUTION: *Do not allow the gasket material to enter bearing or shaft areas or oil passages.*



Liquid gasket areas

27. Install the lower crankcase half onto the upper half, engaging each gearshift fork with its gear groove.



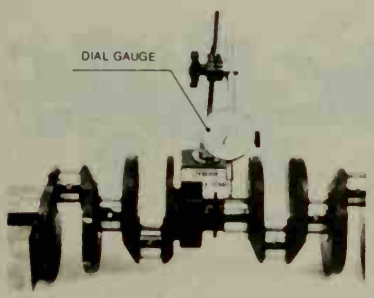
Follow the tightening sequence number when assembling the cases

28. Install the lower crankcase bolts. The tightening sequence numbers are embossed on the lower crankcase half. Tighten the 8 mm bolts to about 11 ft lbs all around, then go back for a final tightening of 16.5–19.5 ft lbs.
29. Tighten the 6 mm bolts to 5.2–7.9 ft lbs.
30. Check that the transmission shafts turn freely and that shifting is smooth.
31. Install the secondary shaft assembly. Refer to the section above for assembly details.
32. The remainder of the procedure is the reverse of disassembly. Refer to the "Crankcase Cover Components" sections for assembly details.

Lower crankcase half bolts

Transmission shaft shim locations

Crankshaft Assembly



REMOVAL

1. Remove the engine from the frame.
2. Remove the top end components: cams, cylinder head, cylinders, pistons.
3. Remove the transmission.
4. Lift out the crankshaft and primary chain and camshaft chain. Remove the two chains from the crankshaft.

INSPECTION

Crankshaft

1. Blow out the crankshaft oil passages with compressed air.
2. Mount the crankshaft on a set of v-blocks and check the run-out at the center main bearing with a dial gauge. Run-out will be the true indicated reading.

Checking crankshaft run-out with a dial gauge

Standard run-out is under 0.02 mm (0.0008 in.). If run-out exceeds 0.05 mm (0.0020 in.), the crank should be replaced.

3. Measure the main bearing clearance with Plastigauge®. Cut strips of the material to the width of the bearings and place them on the crank journals parallel with the crank. Install the lower crankcase. Tighten the lower crankcase 8 mm bolts to about 11 ft lbs all around in the order stamped on the crankcase, then go back and tighten them to a final torque of 16.5–19.5 ft lbs. Be sure not to turn or disturb the crankshaft during the operation. Remove the crankcase half and measure the width of the strips. The measured width is the bearing clearance.

Measuring bearing clearance with plastigauge

Standard bearing clearance is 0.034–0.076 mm (0.0013–0.0030 in.). If the clearance exceeds 0.11 mm (0.0043 in.), the bearing inserts should be replaced, and the crankshaft journals checked for wear.

4. Measure each of the crankshaft journals. Standard diameter is 35.984–36.000 mm (1.4167–1.4173 in.). If the diameter is less than 35.964 mm (1.4159 in.), or if the journals are scored, the crankshaft should be replaced.

Measuring the crankshaft journal diameter

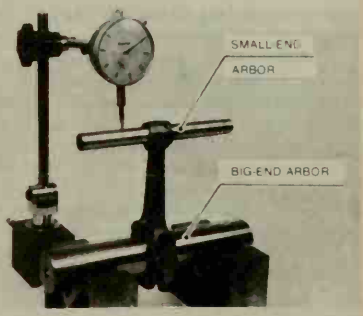
Checking crankshaft side clearance

5. Install the crank in the crankcase half. Levering it to one side, as illustrated, measure the side clearance with a feeler gauge. Standard side clearance is 0.05–0.15 mm (0.0020–0.0059 in.). If clearance exceeds 0.40 mm (0.0157 in.), the crankcases must be replaced.

NOTE: *The cases are machined in pairs and must be replaced as a set.*

Connecting Rods

1. To remove the connecting rods, remove the big end cap nuts and pull off the rods. Be sure to mark them for location. Do not mix the rods and caps. Caps can only be installed on their own rod.



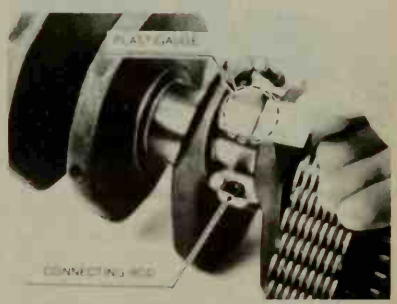
Measuring connecting rod side clearance

2. Check the rod big end side clearance, using a feeler gauge between the big end and the crank flywheels.

Standard clearance is 0.15–0.25 mm (0.0059–0.0098 in.) If clearance exceeds 0.45 mm (0.0177 in.), replace the rod.

3. Remove the con rod bearing inserts. Mount the rod as illustrated and measure the con rod bend over a 100 mm distance. Standard bend is under 0.05 mm (0.002 in.) Replace the rod if bend exceeds 0.2 mm (0.008 in.).

4. Turn the rod 90° and measure twist.



Checking the rod for a bent condition

Standard twist is under 0.05 mm (0.002 in.). Replace the rod if twist exceeds 0.2 mm (0.008 in.) over a 100 mm distance.

NOTE: *If any or all of the rods are to be replaced, be sure that each pair of rods (1 and 2 or 3 and 4) have the same weight mark. The weight mark is a capital letter stamped on the big end.*

5. Check con rod bearing clearance with Plastigauge®. Standard clearance is 0.041–0.067 mm (0.0016–0.0026 in.) If clearance exceeds 0.1 mm (0.0040 in.), replace the bearing inserts.

Measuring rod bearing clearance with plastigauge

6. If the con rod bearings are in need of replacement, the correct size insert must be chosen. To do this, first measure each of the rod journals with a micrometer.

If the measured journal diameter is less the 34.97 mm (1.3768 in.), replace the crankshaft.

Standard journal diameter is 34.984–34.994 mm (1.3773–1.3777 in.). If the measured diameter is less than this amount, but not under the serviceable limit, use new bearing inserts marked with *blue* paint.

If the measured diameter of the journal is 34.984–34.994 mm (1.3773–1.3777 in.), do not mark it.

If the diameter is 34.995–35.000 mm (1.3778–1.3780 in.) mark the journal with a "zero."

NOTE: *Ignore any marking already on the crankshaft.*

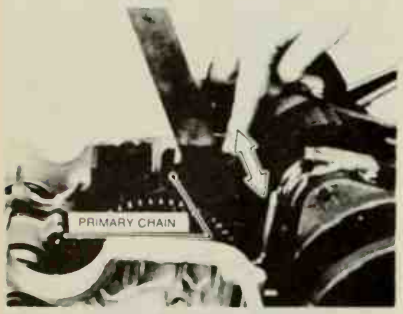
Bolt the rod and cap together with the bearing inserts removed. Tighten the rod bolts to 16–19 ft lbs, the standard torque. Measure the inside diameter of the rod big end.

If the inside diameter is 38.009–38.016 mm (1.4964–1.4967 in.), mark the rod with a "zero."

If the inside diameter is 38.000–38.008 mm (1.4961–1.4964 in.), do not mark the rod.

Refer to the following chart and cross-reference the rod and crank markings to determine which bearing inserts to use.

Bearing Insert Chart



Crankshaft Marking	Con-Rod Marking 0	No mark
0	Black (PN 13034-051)	Brown (PN 13034-052)
No mark	Blue (PN 13034-050)	Black (PN 13034-051)

Bearing insert thicknesses are as follows.

Blue 1.485–1.490 mm/0.0585–0.0587 in
Black 1.480–1.485 mm/0.0583–0.0585 in.
Brown 1.475–1.480 mm/0.0581–0.0583 in.

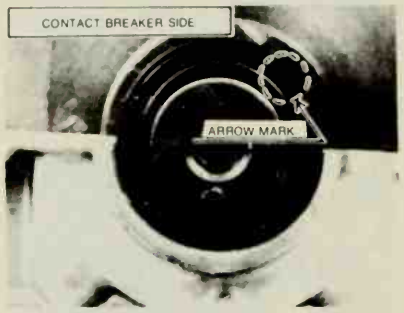
Primary Chain

1. With the crankshaft and the secondary shaft in place, check the primary chain slack. Replace the primary chain if slack exceeds 27 mm (1.08 in.).
2. The replacement chain is a Tsubakimoto Hy-Vo 3/8P-1W 76-link chain.

Checking primary chain free-play

Camshaft Chain

Stretch the chain by applying a force of about 5 kg. (10.4 lbs.), and measure the length of a 20-link section of the chain.



The standard length is 160.0 mm (6.30 in.) The chain should be replaced if the 20-link section measures more than 162.4 mm (6.39 in.).

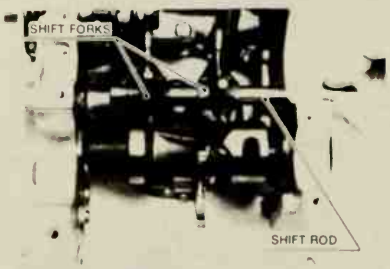
INSTALLATION

1. Lubricate the bearing inserts thoroughly and install each rod on its own journal. Be sure that the rod caps are correctly installed. Fit the caps onto the rods so that the weight marks align. Install and tighten the rod nuts to 16–19 ft lbs.

Install the caps on the rods so that the weight marks align

2. Lubricate the crankshaft bearings. Be sure that the primary and cam chain are fitted and properly engaged on their sprockets. Install the crankshaft in the upper crankcase half.
3. Apply high-temperature grease to the lips of the oil seals and fit the seals to either side of the crankshaft. The arrows on the faces of the seals must face *outwards*. The arrows should indicate the direction of crankshaft rotation (clockwise from the right side of the engine).
4. Fit the crankcase halves together as outlined in the "Splitting the Crankcases" section.

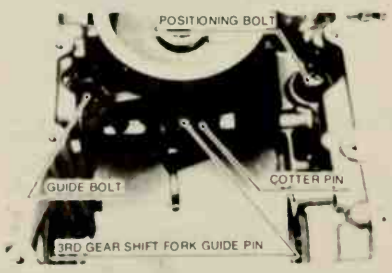
Oil seal installation



Transmission

REMOVAL

1. Split the crankcases.
2. Remove the transmission gear shafts from the upper case half.



NOTE: *Do not disassemble the shafts unless it is necessary. Components can be inspected in place (see below). Shaft circlips are not reusable and must be replaced with new ones on assembly.*

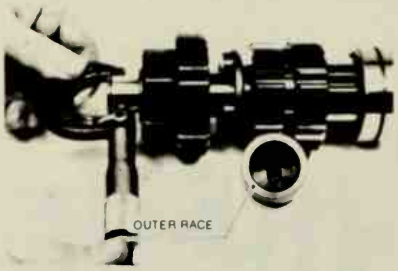
3. Pull out the shift rod and remove the two shift forks from the lower case half.

Removing the shift rod

4. Remove the shift drum positioning bolt, spring, and pin.
5. Bend down the washer tab and remove the shift drum guide bolt.

6. Remove the cotter pin and remove the 3rd gear shift fork guide pin.
7. Remove the operating plate circlip and the plate.
8. Pull the shift drum out a small way and remove the 3rd gear shift fork. Remove the shift drum from the crankcase.

INSPECTION



1. Lubricate the transmission shaft bearings and check their rotation. It should be smooth, effortless, and noiseless. If the rotation is rough or halting, or if play is noticeable in the outer race, the bearings should be replaced.

Replace bearings as a set.

2. Check the needle bearings for flattened or discolored needles. Replace them if damage is noted.

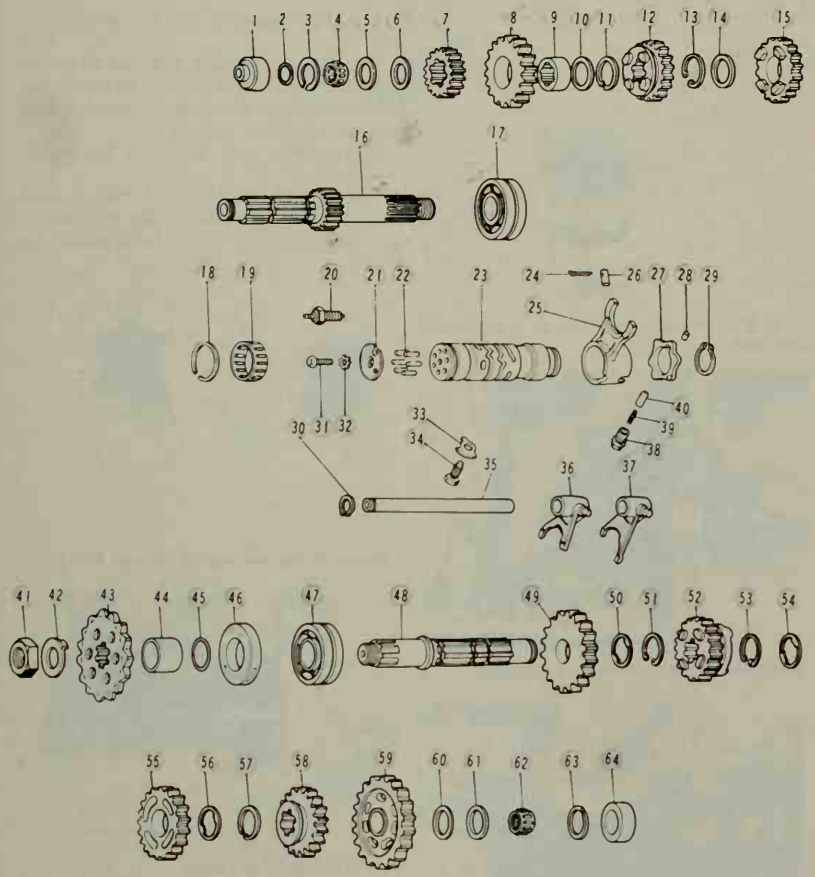
Measure the diameter of the transmission shafts where the needle bearings ride, and also the outer races of the needle bearings.

Standard shaft diameter is 19.980–19.993 mm (0.7866–0.7871 in.). Replace the shaft and the needle bearing if the measured diameter is less than 19.96 mm (0.7858 in.).

Checking needle bearing wear

Measure the inside diameter of the outer needle bearing races. Standard diameter is 26.014–26.024 mm (1.0242–1.0245 in.). Replace the outer race and the needle bearing if the measured inside diameter is 26.04 mm (1.025 in.).

3. Make a visual inspection of the gears. Look for pitting of the gear teeth. This will be most noticeable at the very base of the teeth. Gears with pitted teeth should be replaced, as should the gear with which they mesh.



Check the gear dogs for chipping or wear. Check the gear dog holes and recesses for wear and damage.

Some of the gears are splined to the shafts, others rotate freely. Check that the freely rotating gears can do so without binding or rough rotation. The bush inside diameters of these gears should be measured if the shafts are disassembled. Refer to "Disassembly," below.

4. Install the transmission shafts in the crankcase and check the backlash of each of the pairs of gears with a dial gauge. Set the gauge against one of the gears and attempt to rotate it while holding the meshing gear steady. Standard backlash is 0.17 mm (0.007 in.). Replace any pair of gears where backlash exceeds 0.25 mm (0.010 in.).

62. Needle bearing
63. Circlip
64. Bearing outer race

Transmission and shift drum assembly

5. Visually inspect the shift forks for chipping or wear to the fingers. Measure the thickness of each of the shift fork fingers. Standard thickness is 4.9–5.0 mm (0.19–0.20 in.). Replace any fork on which the fingers measure less than 4.7 mm (0.18 in.).

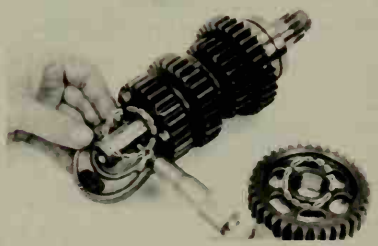
6. Measure the gear shift fork groove width on the gears. Standard width is 5.05–5.15 mm (0.199–0.203 in.). Replace the gears if the width is wider than 5.25 mm (0.207 in.).

7. Measure the diameter of each shift fork guide pin. For the 3rd gear shift fork, standard diameter is 7.985–8.000 mm (0.3144–0.3150 in.) and the fork should be replaced if the measured diameter is less than 7.93 mm (0.312 in.). For the 4th and 5th gear shift forks, standard diameter is 7.9–8.0 mm (0.311–0.315 in.), and the forks should be replaced if the pin measures less than 7.85 mm (0.309 in.).

8. Measure the diameter of each shift drum groove. Standard groove width is 8.05–8.20 mm (0.317–0.323 in.). Replace the shift drum if the groove width is greater than 8.25 mm (0.325 in.).

9. Measure the length of the shift drum positioning spring. Standard spring free-length is 32.3 mm (1.27 in.). The spring should be replaced if it measures less than 30.7 mm (1.21 in.).

SHAFT DISASSEMBLY AND ASSEMBLY



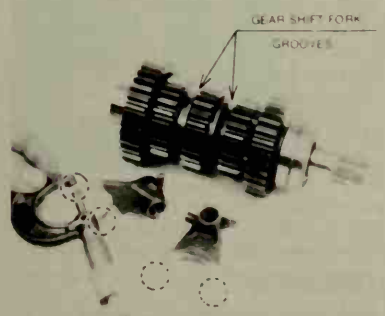
1. Have new circlips on hand before disassembling the shafts. Once removed, circlips cannot be reused. Lay out each piece as it is removed to facilitate assembly.

2. To disassemble the drive shaft: remove the sleeve and spacer. Remove the needle bearing outer race. Remove the circlip and remove the needle bearing, steel and copper washers. Remove the 2d and 5th gears. Remove the copper bushing and washer. Remove the circlip and remove the 3rd gear. Remove the circlip and remove the washer and the 4th gear. Remove the ball bearing from the shaft using a puller.

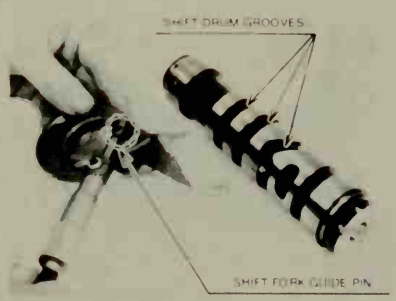
3. To disassemble the output shaft: remove the needle bearing outer race. Remove the circlip and pull off the needle bearing and the steel and copper washers. Remove the 1st and 4th gears. Remove the circlip and remove the splined washer, 3rd gear, and splined washer. Remove the circlip and the 5th gear. Remove the circlip, splined washer and 2d gear. Remove the ball bearing using a bearing puller.

4. Check gear-to-shaft clearance by measuring the inside diameter of each of the bushed gears and the corresponding area of the shaft on which they ride.

Standard clearance for 2d, 3rd, 4th, and 5th gears (both output and and drive shafts) is 0.020–0.062 mm (0.0008–0.0024 in.). Replace the gear(s) if clearance exceeds 0.16 mm (0.0063 in.).

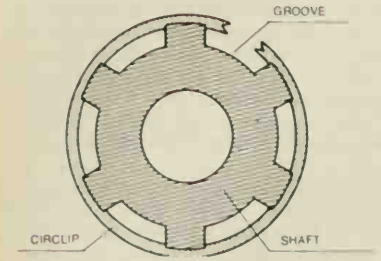


Measuring shaft and gear clearance

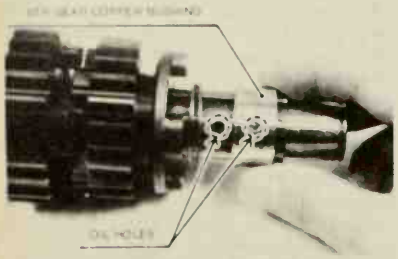


Standard clearance for the 1st output shaft gear is 0.014–0.048 mm (0.0006–0.0019 in.). Replace the gear if clearance exceeds 0.15 mm (0.006 in.)

5. Assemble the shafts in the reverse of the disassembly order. Use *new* circlips.

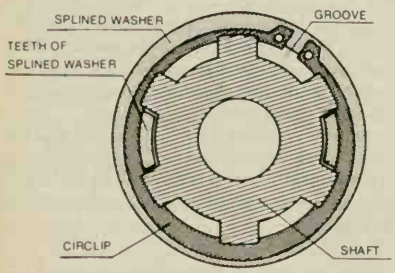


6. For the drive shaft, install the circlips so that the opening of the circlips aligns with one of the grooves in the shaft. Be sure to install the 5th gear copper bushing so that the oil



Checking gear shift fork finger wear

Checking the gear shift fork pins and drum grooves for wear



Correct circlip installation

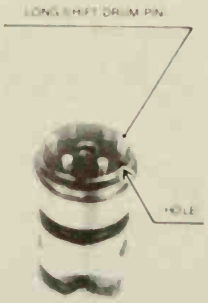
When fitting the 5th gear copper bushing, align the oil holes

hole in the bushing aligns with the oil hole in the shaft.

The proper assembly order for the drive shaft is: 1st gear (part of the shaft) 4th gear, washer, circlip, 3rd gear, circlip, washer, copper bushing, 5th gear, 2d gear, copper washer, steel washer, needle bearing, circlip, bearing race.

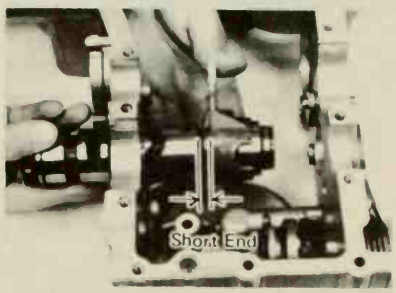
7. To assemble the output shaft, install the circlips so that the opening of the circlip aligns with one of the shaft grooves. Install the splined washers so that their teeth do not coincide with the circlip opening.

Correct splined washer and circlip installation



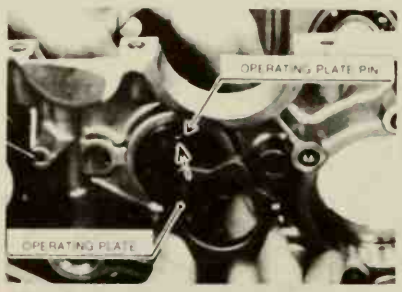
The proper assembly order is: (starting from the engine sprocket side (2d gear, splined washer, circlip, 5th gear, circlip, splined washer, 3rd gear, splined washer, circlip, 4th gear, 1st gear, copper washer, steel washer, needle bearing, circlip, bearing race.

INSTALLATION



1. If the shift drum pins have been removed, make sure that the long pin is installed in the proper hole. Refer to the illustration. Use a new pin plate screw lockwasher and be sure that the pin plate screw is firmly tightened.

2. Install the needle bearing, pressing it on so that the end of the bearing is even with the left end of the hole.

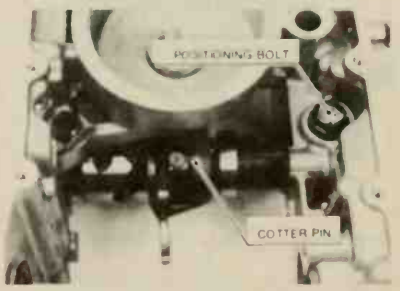


3. Place the 3rd gear shift fork into position in the crankcase half positioned so that the short side faces the neutral indicator switch.

Be sure that the long shift drum pin is positioned as shown

Install the 3rd gear shift fork as illustrated

Fitting the operating plate



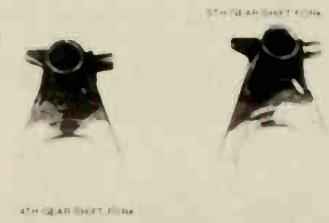
Install the shift drum sliding it through the shift fork.

4. Install the operating plate onto the shift drum and fit its circlip.

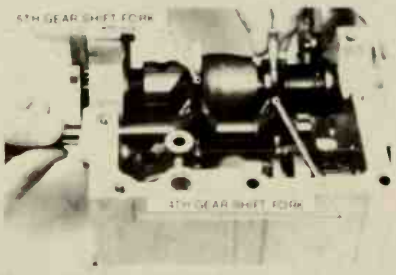
5. Seat the shift drum guide bolt washer in the crankcase and install and tighten the bolt. Bend the tab over the flat of the bolt.

6. Install the 3rd gear shift fork guide pin and use a new cotter pin. The shift fork pin should be inserted into the middle of the three shift fork grooves. The cotter pin should be inserted from the long side of the shift fork.

7. Install the shift drum positioning pin, spring, and bolt.



Insert the cotter pin from the right side. Do not forget the positioning bolt



8. Set the shift drum into the neutral position.

9. Lubricate the shift rod and shift fork fingers. Insert the rod, running it through the two shift forks while fitting the shift fork pins into the shift drum grooves.

NOTE: *The shift forks are not interchangeable.*

The 4th gear shift fork has fingers of about equal length. Note their proper positions on the shift rod by referring to the accompanying illustration.

Differentiate the 4th and the 5th gear shift forks

Proper shift fork installation

Kickstarter

REMOVAL

1. Split the crankcases. The transmission can remain in place.

2. Remove the spring guide. Remove the kickstarter return spring.

3. Remove the circlip from the shaft bushing. Remove the shaft stopper screws and stopper and pull off the bushing.

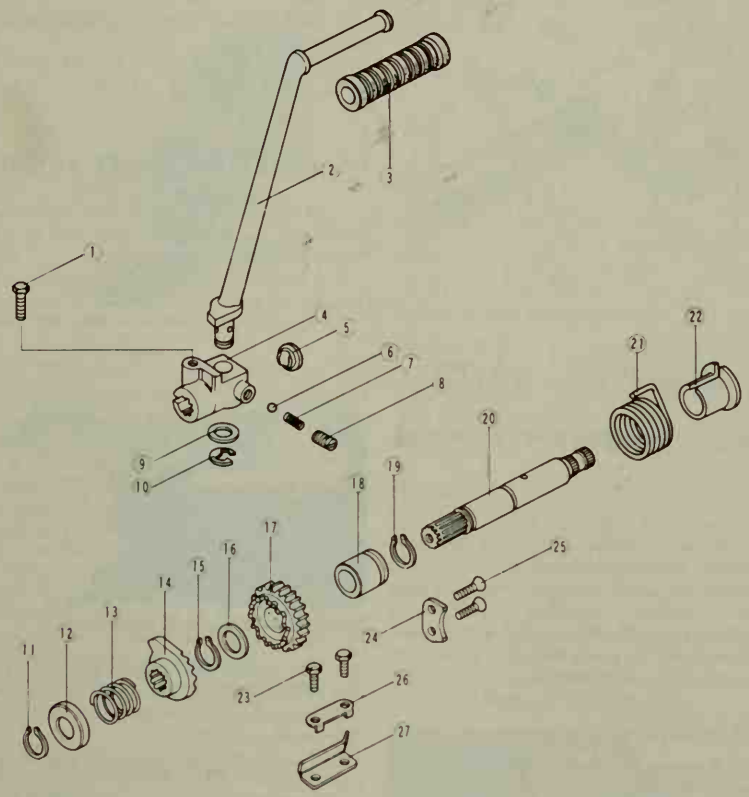
4. Remove the shaft assembly.

5. Straighten the lockwasher ends and remove the stopper.

6. Remove the circlip on the end of the shaft and remove the spring seat, spring, and ratchet gear.

7. Remove the circlip, and take off the washer and kick gear.

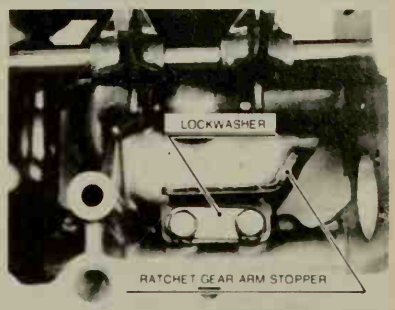
INSPECTION



1. Make a visual inspection of the kick gear, and replace it if there is any damage to the gear teeth or to the ratchet mechanism.

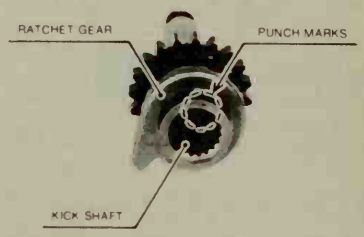
2. Measure the inside diameter of the kick gear. Standard diameter is 20.000–20.021 mm (0.7874–0.7882 in.). Replace the gear if the inside diameter exceeds 20.07 mm (0.790 in.).

3. Measure the diameter of the kickstarter shaft in the area on which the kick gear rides. Standard shaft diameter is 19.959–19.980 mm (0.7858–0.7866 in.). Replace the shaft if the diameter is less than 19.94 mm (0.7850 in.).



INSTALLATION

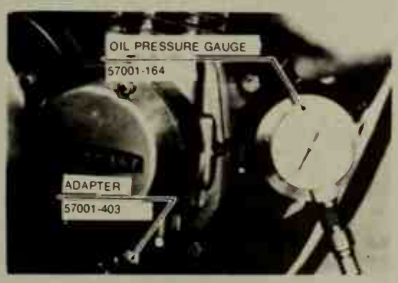
Installation is the reverse of removal. Note the following points:



1. Bolt
2. Kick pedal
3. Pedal rubber
4. Boss
5. Plug
6. Steel ball
7. Spring
8. Screw
9. Washer
10. Circlip
11. Circlip
12. Spring seat
13. Spring
14. Ratchet gear
15. Circlip
16. Washer
17. Kick gear
18. Bushing
19. Circlip
20. Kick shaft
21. Kick spring
22. Spring guide
23. Bolt
24. Stopper
25. Screw
26. Lockwasher
27. Stopper

Kickstarter shaft assembly

Install the ratchet gear arm stopper as shown



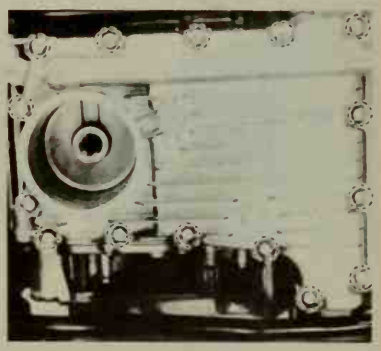
Align the shaft and ratchet gear punch marks when installing

1. Install the ratchet gear arm stopper as shown in the illustration. Use a new lockwasher. Tighten the two stopper bolts to 5.1–6.5 ft lbs. Be sure to bend the ends of the lockwasher over the stopper bolts.
2. Lubricate the gears with engine oil and the bushing with some high temperature grease before installation.
3. When installing the ratchet gear, align the punch mark on the gear with the punch mark on the shaft.
4. After tightening the kickstarter shaft stopper screws, peen both screw heads to prevent loosening.

LUBRICATION SYSTEM

OIL PRESSURE

1. To check the oil pressure, a special gauge (No. 57001-164) and adapter (No. 57001-403) are needed.
2. Oil pressure should be checked when the engine is at normal operating temperature.



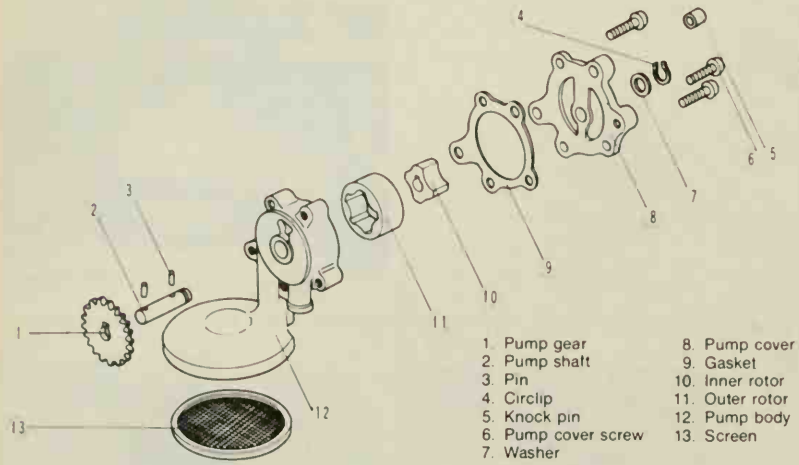
Checking oil pressure

3. With the engine *off*, remove the oil passage plug below the breaker points case. Be cautious of the hot oil. Fit the adapter and gauge.
4. Start and run the engine to 4,000 rpm. Oil pressure should be 28–36 psi.
5. If oil pressure is significantly below this figure, remove and inspect the oil pump and oil pressure relief valve.
6. The oil pressure gauge is also used to check oil pressure relief valve operation. This item is checked with the engine *cold*.
7. When checking with the oil cold, measured pressure should not fall too much below 63 psi nor exceed 85 psi regardless of rpm. If the oil pressure is too low, the relief valve may be stuck open. If it is too high, the relief valve may be stuck in the closed position. Refer to the appropriate section below for relief valve inspection.

OIL PUMP

Removal

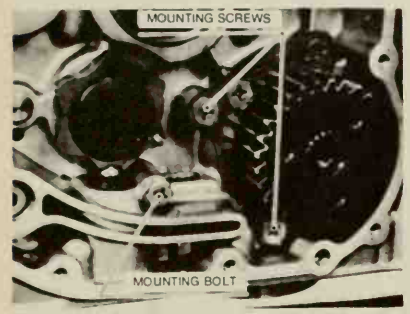
1. With the motorcycle placed on the center stand, remove the drain plug and drain off the oil. Remove the oil filter as well.
2. After the oil has been drained, install the drain plug and tighten it to 9.5–12.0 ft lbs.
3. Remove the mufflers.
4. Remove the clutch. Refer to the "Engine and Transmission" chapter.
5. Remove the 15 oil pan bolts and remove the pan. Remove the gasket and the three oil passage o-rings.



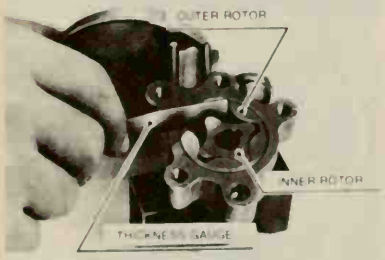
Oil pan bolts

6. Remove the oil pump mounting bolt and the two mounting screws and take off the pump. Note that there are two knock pins on the crankcase.

Inspection



1. Measure the clearance between the inner rotor and the outer rotor. Standard clearance is 0.05–0.23 mm (0.0020–0.0091



Oil pump components

in.). The rotors should be replaced if clearance exceeds 0.30 mm (0.012 in.).

2. Measure the clearance between the outer rotor and the pump body. Standard clearance is 0.15–0.21 mm (0.0059–0.0083 in.). Replace the rotors or the oil pump body if the clearance exceeds 0.30 mm (0.012 in.).

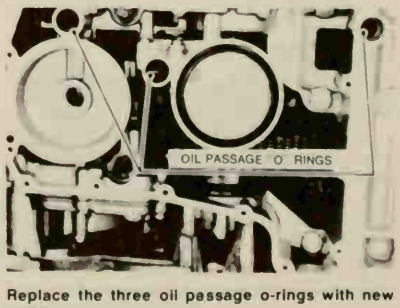
Oil pump mounting screws and bolt

Checking inner-to-outer rotor clearance

Checking rotor side clearance

3. Place a straightedge across the pump body and then probe beneath it with a suitably sized feeler gauge blade to determine rotor side clearance. Standard clearance is 0.02–0.07 mm (0.0008–0.0028 in.). Replace the rotors or the pump assembly if clearance exceeds 0.12 mm (0.0047 in.).

Disassembly



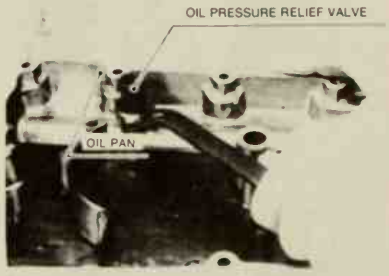
1. Remove the circlip and washer on the pump shaft end.
2. Remove the oil pump cover screws and remove the pump cover and gasket.
3. Remove the rotors.
4. Remove the pin and pull off the oil pump gear and shaft.
5. Slide off the pump gear and take the pin from the shaft.

Assembly

1. Assembly is the reverse of disassembly. Use a new gasket. Be sure that all of the internals are well oiled and the pump turns smoothly after assembly.

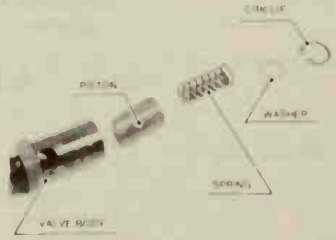
Installation

1. Before installing the oil pump, fill it with clean motor oil.
2. Check that the two knock pins are in place.
3. Be sure that the oil pump gear and the pump drive gear are properly meshed.
4. Use a non-permanent thread-locking compound on the oil pump mounting bolt. Peen the two mounting screws to lock them in place.



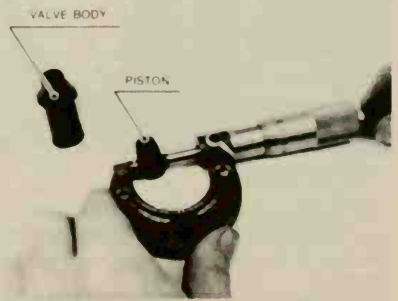
Replace the three oil passage o-rings with new ones

5. Replace the three oil passage o-rings with new ones.
6. Tighten the oil pan bolts to 5.1–6.5 ft lbs.



OIL PRESSURE RELIEF VALVE

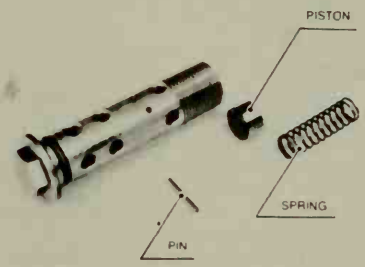
1. The oil pressure relief valve is fitted to the oil pan. To remove the pan, refer to "Oil Pump: Removal," Steps 1–5.
2. Unscrew the relief valve and remove it from the oil pan.



Removing the oil pressure relief valve

3. For models with engine numbers prior to KZ650BE000144, the relief valve can be disassembled and inspected. This cannot be done for later models.
4. To disassemble the relief valve on engines prior to KZ650BE000144, press down on the washer with a screwdriver and take out the circlip. Remove the washer, spring, and piston.
5. Check the piston and the inside of the valve body for scoring or other signs of wear.

Relief valve components (early)



6. Measure the diameter of the piston and the inside diameter of the valve body to determine piston-to-body clearance. The standard specification is 0.020–0.103 mm (0.0008–0.0041 in.). Replace the piston if clearance exceeds 0.13 mm (0.0051 in.).

Measuring relief valve piston diameter (early)

Checking relief valve operation (late)

Oil filter by-pass valve components

7. Check the valve spring free length. The standard specification is 20.1 mm (0.79 in.), and the spring should be replaced if it is less than 19.1 mm (0.75 in.) long.

8. For models after Engine No. KZ650BE000144, the oil pressure relief valve cannot be disassembled. The only check is to push on the steel ball in the valve body with a wooden dowel or the like and make sure that it slides smoothly and is fully seated by the valve spring pressure. Any rough movement which cannot be cured by cleaning the valve assembly thoroughly in a solvent will necessitate replacing the valve assembly.

CAUTION: *Do not attempt to disassemble the valve.*

OIL PRESSURE INDICATOR SWITCH

1. The switch should go on when the ignition is turned on. If it does not, check it by first disconnecting the switch lead. Then, connect the positive lead of a 30V DC voltmeter to the lead, and ground the negative meter lead on the engine. Turn on the ignition switch. The voltmeter should read battery voltage. If it does not, the trouble is either a broken wire or a burned-out warning light bulb.

2. If the voltmeter does read battery voltage, the oil pressure switch may be defective. To check this, use an ohmmeter to check for continuity between the switch terminal and the switch body. If the switch leads are disconnected, any reading other than zero ohms indicates that the switch is defective.

3. If the switch does not turn the warning light out at any engine speed above idle, check the oil pressure with a pressure gauge as outlined at the beginning of this chapter. If oil pressure is satisfactory, the switch is defective and should be replaced.

BY-PASS VALVE

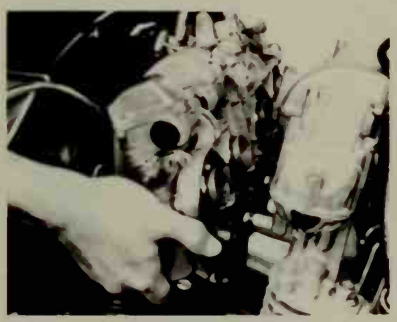
1. The by-pass valve consists of a piston and spring and is fitted inside the oil filter bolt. No routine maintenance is required.

2. If disassembly of the by-pass valve is desired, remove the pin and take out the spring and piston. Clean them thoroughly in solvent and lubricate them with clean motor oil before refitting.

3. Filter bolt rubber o-ring condition is critical. If the o-rings are chipped, hardened, or torn, or if there is any doubt as to their condition, they should be replaced with new ones.

FUEL SYSTEM

CARBURETOR OVERHAUL (650)

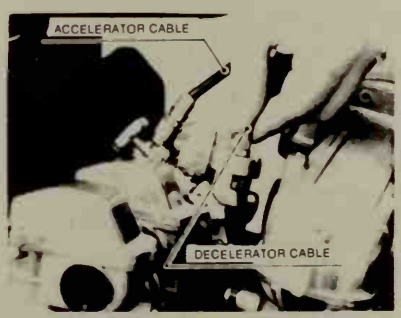


Removal

1. Remove the gas tank. Drain the carburetor float bowls.

2. Screw in the throttle cable adjusters near the twist-grip to give the cables plenty of play.

3. Loosen the manifold clamp for each carburetor.



4. Move the spring bands which secure the air cleaner hoses to the carburetors.

Removing the carburetors

5. Pull the carburetors off the manifolds as an assembly.

6. Loosen the throttle cable adjuster nuts and disconnect the cables from the pulley. Remove the carburetors from the motorcycle.

Disconnecting the cables

Installation

1. Installation is basically the reverse of removal. Note the following points:

2. Be sure that the throttle cables are correctly routed. They should run between the top frame tube and the right side cradle tube without sharp bends or kinks. Be sure that they are not twisted around each other.

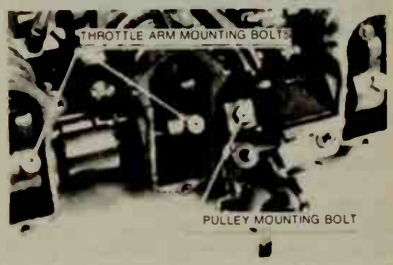
3. After installing the cables onto the pulley, center the adjusting nuts on the bracket.

4. After fitting the carburetors onto the manifolds, be sure that the clamps are properly tightened and that the air cleaner hose spring bands are in place.

5. The carburetor overflow tubes are routed to the right rear of the engine. The air vent tubes are routed to the sides of the battery housing between the air cleaner and the baffle plate.

6. Adjust the throttle cables after installing the carburetors.

Separation



All carburetor components with the exception of the linkage mechanism and starter plungers can be removed and inspected without separating the carburetors from their mounting plate. If this separation is required, proceed as follows:

1. Remove the carburetors from the motorcycle.

2. Remove the idle adjusting screw and spring.

3. Remove the carburetor covers.

4. Unscrew and remove the throttle arm mounting bolts and the pulley mounting bolt. Note the lockwashers on each bolt.

Remove the throttle arm mounting bolts and the pulley mounting bolt

Remove the throttle shaft set plate and rubber cap

5. Remove the throttle return spring.

6. Remove the phillips screw and take off the throttle shaft set plate.

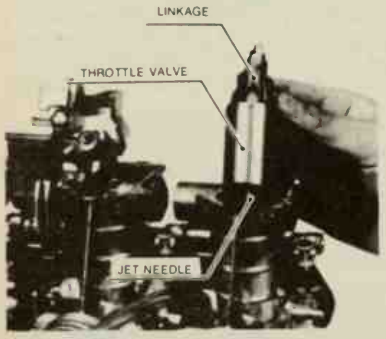
7. Remove the rubber shaft caps from the end carburetors.

8. Pull the throttle shaft out to the left side.

9. Remove the mounting screws and take off the carburetors.

10. To refit the carburetors, reverse the separation procedure. Note the following points:

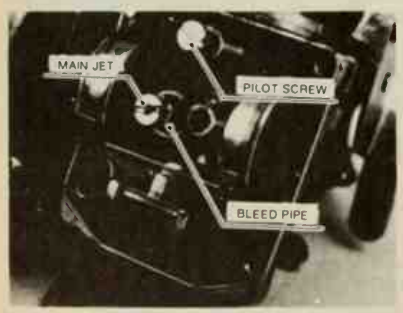
a. Use a non-permanent thread-locking compound on the mounting screws.



b. Apply a thin coat of grease to the throttle shaft before inserting it through the carburetors.

c. Perform a mechanical synchronization of the carburetors (see below).

Disassembly



As noted, all carburetor components with the exception of the linkage mechanism and the starter plungers can be removed without separating the carburetors from their mounting plate. To disassemble the carburetors in this manner, proceed as follows:

1. Refer to Steps 1–8 under "Separation" above.
2. Lift out the linkage and throttle valve assemblies.
